rina Eudoxia, who was suspected of complicity in the conspiracy, which had been the work of the old Russian or anti-reform party, was divorced, and shut up in a convent; the czar's own sister, Martha, was likewise compelled to take the veil. To show his gratitude to his faithful adherents, P. conferred upon the chief of them the Order of St. Andrew, now first instituted. He put the press on a proper footing, caused translations of the most celebrated works of foreign authors to be made and published, and established naval and other schools. At this period, the ordinary arithmetic was first introduced for the management of accounts, these having been previously kept by means of balls strung on a wire (the Tartar-method). P. also introduced the mode of raising revenue by taxation of commodities in common use. Trade with foreign countries, which was formerly punished as a capital crime, was now permitted, or rather, in the case of the principal merchants, insisted upon. Many improvements in dress, manners, and etiquette were introduced authoritatively among the public functionaries, and recommended to the people at large. Even the organization of the national church could not escape P.'s reforming zeal.

In 1700, P., desirous of gaining possession of Carelia and Ingria, provinces of Sweden, which had formerly belonged to Russia, entered into an alliance with the kings of Poland and Denmark to make a combined attack on Sweden, taking advantage of the tender age of its monarch, Charles XII.; but he was shamefully defeated at Narva, his raw troops being wholly unable to cope with the Swedish veterans. P. was by no means disheartened, for, taking advantage of the Swedes being employed elsewhere, he quietly appropriated a portion of Ingria, in which he laid the foundation of the new capital, St. Petersburg, 27th May 1703. Great inducements were held out to those who would reside in it, and in a few years it became the Russian commercial dépot for the Baltic. In the long contest with Sweden, the Russians were almost always defeated, but P. rather rejoiced at this, as he saw that these reverses were administering to his troops a more lasting and effective discipline than he could have hoped to give them in any other way. He had his revenge at last, in totally routing the Swedish king at Poltava (q. v.), 8th July 1709, and in seizing the whole of the Baltic provinces and a portion of Finland in the following year. His success against Sweden helped much to consolidate his empire, and to render his subjects more favorably disposed towards the new order of things. After re-organizing his army, he prepared for strife with the Turks, who, at the instigation of Charles XII. (then residing at Bender), had declared war against him. See OTTOMAN EMPIRE. In this contest, P. was reduced to such straits that he despaired of escape, and, looking forward to death or captivity, wrote a letter to his chief nobles, cautioning them against obeying any orders he might give them while a captive, and advising them regarding a successor to the throne in case of his death. But the finesse and ability of his mistress, Catharine, afterwards his wife and successor (see CATHARINE I.), extricated him from his difficulties; and a treaty was concluded (23d July 1711) by which Peter lost only his previous conquest—the port of Azof and the territory belonging to it. Shut out from the Black Sea, the possession of a good sea-board on the Baltic became the more necessary to him, and the war against Sweden in Pomerania was accordingly pushed on with the utmost vigor.

On 2d March 1712, his marriage with his mistress, Catharine, was celebrated at St. Petersburg; and two months afterwards, the offices of the central government were transferred to the new capital. His arms in Pomerania and Finland were crowned with success, and in 1713 the latter province was completely subdued. P. neglected nothing to develop the naval power of the empire, and the strictness with which he enforced the discharge of their duties on his ministers and officers, appears from the refusal, by the court of admiralty, of the czar's own application for the grade of vice-admiral, until by defeating the Swedish fleet at Hangoend, and taking the Åland Isles, and several coast forts in Finland, he had merited the honor. In the end of 1716, and beginning of 1717, in company with the zarina, he made another tour of Europe, this time visiting Paris, where he was received with great empressement, and returned to Russia in October 1717, carrying with him books, paintings, statues, &c., to a large amount. It was soon after this time that he ordered his son Alexei (q. v.) to be executed, and many of the nobles who had been implicated in his treasonable plans were punished with savage barbarity. In 1721 peace was made with Sweden, and on condition of that power giving up the Baltic provinces, Ingria (now government of St. Petersburg), Viborg, and Kexholm, and a small portion of Finland, with all the islands along the coast from Courland to Viborg, she received back the rest of Finland, with a sum of £400,000. In 1722 P. commenced a war with Persia, in order to open up the Caspian Sea to Russian commerce (see PERSIA). The internal troubles of Persia compelled the shah to yield to the demands of his formidable opponent, and to hand over the three Caspian provinces along with the towns of Derbend and Baku.

On P.'s return to his capital, he inquired into the conduct of his finance ministers, and punished with fines, imprisonment, and even death, those whom he detected in fraudulent acts. To save the empire which he had established and constituted from being abandoned to the weak government of a minor, he, in February 1722, promulgated his celebrated law of succession (see PETER II.). For the last years of his life he was chiefly engaged in beautifying and improving his new capital, and carrying out plans for the more general diffusion of knowledge and education among his subjects. In the autumn of 1724 he was seized with a serious illness, the result of his imprudence and now habitual excesses; and after enduring much agony, he expired, 8th February 1725, in the arms of the empress.

PETER II., ALEXEIVITCH, Czar of Russia, was the sole male representative of Peter the Great, being the son of the unfortunate Alexei (see Peter I.) by his wife the Princess Charlotte of Brunswick-Wolfenbützel, and was born 23d October 1715 at St. Petersburg. On the death of the Zarina Catharine I., he ascended the throne, May 17, 1727, in accordance with a decree of Peter the Great, which enjoined that each czar should name his successor; and the ambitious Menchikoff, who hoped to govern more easily in the name of a minor, prompted the empress to choose P. In order to secure himself in his high position, Menchikoff affianced one of his daughters to the youthful czar, and compelled his relative, Anna Petrowna, and her husband, the Duke of Holstein, to retire to their own estates. But, notwithstanding these and other precautions, his power was overturned by a mere child, a playfellow of the boy-ruler, who was of the powerful family of Dolgorouki. Instigated by his friends, this boy, Ivan Dolgorouki, opened the eyes of his sovereign to the humiliating dependence in which he was held by Menchikoff, and inspired him with a strong desire to free himself. The plan succeeded, and the minister and his family were exiled to Siberia, the Dolgorouki family taking their place as favorites. The marriage of a lady of this family with P. had been arranged, and was almost on the point of being celebrated, when he was seized with small-pox, and died at St. Petersburg, January 29, 1730. During his reign, the three Caspian provinces, Asterabad, Ghilan, and Mazanderan, which had been seized by Peter the Great, were recovered by Persia.

PETER III., FEODOROVITCH, Czar of Russia, grandson of Peter the Great (being the son of his eldest daughter Anna Petrowna, wife of Carl Friedrich, Duke of Holstein-Gottorp), was born at Kiel, March 4, 1728, and on November 18, 1742, was declared by the zarina Elizabeth (q. v.), her successor to the throne of Russia. From the time of his being publicly proclaimed heir, he lived at the Russian court; and, in obedience to the wishes of the zarina, married Sophia-Augusta, a princess of Anhalt-Zerbst, who, on entering the Greek Church (a necessary condition of marriage of a foreigner with the czar present or presumptive), assumed the name of Catharina Alexiowna. P. succeeded Elizabeth on her death, June 5, 1762; and his first act of authority was to withdraw from the confederate league of France, Austria, and Russia against Prussia, restoring to the heroic monarch of the latter kingdom, Frederic II., the provinces of Prussia Proper, which had been conquered during the Seven Years' War, and sending to his aid a force of 15,000 men; a line of conduct which seems to have been prompted solely by his admiration for the Prussian sovereign. He also recalled many of the political exiles from Siberia, among whom were L'Estocq, Munnich, and the Duke of Courland; abolished the sanguinary law which proscribed any one who should utter a word against the Greek church, the czar, or the government; and then attempted the realization of his favorite project, which was to recover from Denmark that portion of Slesvig which had been ceded to her in 1713, and to avenge the tyranny and annoyances to which his family—that of Holstein-Gottorp—had been subjected. But before the army he had dispatched could reach its destination, a formidable conspiracy, headed by his wife, and supported by the principal nobles, had broken out against him.

This conspiracy originated in the general discontent which was felt at the czar's conduct and government: for the nobility were offended at his liberal innovations, and the preference he showed for Germans; the people and clergy, at his indifference to the national religion, and his ill-concealed contempt for Russian manners and customs; while the whole nation murmured at his servility to Frederic II. of Prussia. His wife had still deeper cause for dislike, for though he was himself addicted to drunkenness and debauchery, he never ceased to reproach her with her infidelities, and had even planned to divorce her, disinherit her son Paul (q. v.), and elevate his mistress Elizabeth Woronzof to the conjugal throne. The revolution broke out on the night of the 8th July 1762; P. was declared to have forfeited his crown, and his wife Catharine was proclaimed zarina as Catharine II. (q. v.) by the Guards, the clergy, and the nobility. P., who was then at Oranienbaum, neglecting the counsels of Field-marshal

Munnich, who proposed to march at once on the capital at the head of the regiments which were still faithful, or at anyrate to take secure possession of Cronstadt and the fleet, soon found even the opportunity of flight cut off, and was compelled to submit. He abdicated the crown on 10th July, and on the 14th of the same month was put to death by Orlof (q. v.), to secure the safety of the conspirators.

PETERBOROUGH, an episcopal city and parliamentary borough of Northamptonshire, stands on the left bank of the Nen—which is thus far navigable for boats—37 miles north-east of Northampton, and 76 miles north-north-west of London by railway. The Great Northern, the Eastern Counties', the Northampton and Peterborough, and the Midland Counties' railways pass the city, and have stations there. P. is regularly laid out, has an excellent grammar-school with an endowment, a corn-exchange in the Italian style, a jail and house of correction, a handsome parish church, and a number of meeting-houses, schools, and charitable institutions.

But the great edifice of P. is the famous cathedral, which holds a high, if not the highest rank among English cathedrals of the second class. The choir and eastern aisles of the transept (built 1118—1138) are early Norman; the transept (1155—1177) is middle Norman; the nave (1177—1193) is late Norman; the western transept (dating from the same period), is transition Norman; the west front, which, as a portico (using that term in its classical sense), is said to be the grandest and finest in Europe, is early English; and the eastern aisle (begun in 1438, but not completed till 1528), is Perpendicular. The beautiful western front consists of three arches 81 feet in height, supported by triangular piers detached from the west wall. Each arch is surmounted by a beautiful pediment and cross. The front is flanked on each side with turrets 156 feet high, and crowned with pinnacles. The roof of the nave is painted in lozenge-shaped divisions, containing figures of kings, bishops, grotesques, &c., in colors. A central tower, lantern-shaped, rises at the intersection of the nave and transept. In the north-choir aisle, a slab of blue stone still covers the remains of Catharine of Aragon. On the stone is carved the simple inscription, 'Queen Catharine, A.D. 1536.' In July 1587, the remains of Mary, Queen of Scots, were brought here from Fotheringay for interment, and here they rested until, twenty-five years after, they were removed to Westminster Abbey. The entire length of the cathedral is 476 feet 5 inches; the breadth of nave and aisles, 78 feet; height of the ceiling of the church, 78 feet; breadth of the church at the great transepts, 203 feet; height of lantern, 135 feet; length of western front, 156 feet; height of central tower from the ground, 150 feet.

P. carries on an active trade in corn, coal, timber, lime, bricks, and stone. Two newspapers are published weekly. P. returns two members to the House of Commons. Pop. (1871) 17,434; (1881) 22,394.

The city had its origin in a great Benedictine monastery, founded in 655 by Oswy, king of Northumbria, and Peada, son of Penda, king of Mercia. This monastery, which became one of the wealthiest and most important in England, was reared in honor of St. Peter; but it was not until after being destroyed by the Danes in 807, and rebuilt about 966, that the town was called Peterborough. On the dissolution of the monasteries, this magnificent edifice was spared, owing, it is supposed, to its containing the remains of Queen Catharine of Aragon.—Murray's *Handbook to the English Cathedrals*.

PETERBOROUGH, LORD. See **MORDAUNT**.

PETERHEAD, a seaport and municipal and parliamentary burgh, in the district of Buchan, Aberdeenshire, on a peninsula, the eastmost point of land in Scotland, 44 miles north-north-east of Aberdeen, by railway. It is irregularly built, clean, and much paved with the reddish granite, called after the town, and used for polishing. The Earls Marischal, before their attainder, 1715, owned much of the parish, and were superiors of the town of P. The property was bought by the Merchant Maiden Hospital of Edinburgh, the governors of which have greatly improved the town and port. P. has no very striking edifices. The parish church has a granite spire, 118 feet high, and a granite Tuscan pillar stands on the market-cross. P. has Episcopal, Free, Roman Catholic, and other churches; an academy and other schools, and two libraries. P. has cloth and winey manufactures, and considerable ship-building. The chief exports are herrings, cod-fish, butter, grain, and granite; and imports, lime, wool, and general merchandise. P. was long the chief British depot of the seal and whale fishing, but the interest has declined.

In 1873, 12 vessels brought home 900 tons of oil, seal-skins, and whalebone, worth £50,000. In 1880, 1073 ships, of 91,687 tons burden, entered the port; and in 1880 it owned 716 fishing-boats, manned by 4296 persons, and cured 171,896 barrels of herrings, beside large quantities of cod and other fish. P. has a harbor on the north, another on the south side of the isthmus of the peninsula on which it is built, and they are connected by a passage

cut across the isthmus, thus allowing vessels to leave the harbor in different winds. On the south side of the bay of P., and about 2½ miles from the town, are the Buchanness and its lighthouse, and Boddam Castle ruins. The Ugie enters the sea a mile north-west of P.; and on its banks, 3 or 4 miles north-west of the town, are the ruined castles of Inverugie and Ravenscraig. The walls of the former are still standing, and access is obtained to the roof by means of a winding staircase in one of the towers, whence a magnificent view may be had of the valley of the Ugie. Ravenscraig stands on the opposite side of the river; it is built upon a rock, and is considered a good specimen of the ancient Scottish baronial style, in the square form so common in the beginning of the 13th century. Its walls are so strong as to have been deemed impregnable previous to the use of artillery. P. unites with Elgin, Kinross, Cullen, Banff, and Inverury in sending a member to parliament; constituency, (1877—8) 1103. Pop. (1841) 4762; (1871) 5535; (1881) 10,992. Annual value of real property, £38,184.

PETERLOO MASSACRE, the name popularly given to the dispersal of a large meeting by armed force in St. Peter's Field, Manchester, Monday, July 16, 1819. The assemblage, consisting chiefly of bodies of operatives from different parts of Lancashire, was called to consider the question of parliamentary reform, and the chair, on open hustings, was occupied by Mr. Henry Hunt. The dispersal took place by order of the magistrates; several troops of horse, including the Manchester Yeomanry, being concerned in the affair, of which an account will be found in *History of the Peace*, by Harriet Martineau, edition of 1858, p. 107. Five or six persons were killed and many wounded. St. Peter's Field is now covered by buildings. Peterloo was a fanciful term, suggested by Waterloo.

PETER'S ST., CHURCH, at Rome, is the largest cathedral in Christendom. It stands on the site of a much older basilica, founded by Constantine, A.D. 306, over the reputed grave of St. Peter, and near the spot where he is said to have suffered martyrdom. This basilica was of great size and magnificence; but had fallen into decay, when Pope Nicholas V., in 1450, resolved to erect a new cathedral, worthy of the dignity and importance of the Roman pontificate, then in the zenith of its power. A design was accordingly prepared by Rossellini on a very grand scale, and the tribune was begun, when the pope died. The new building remained neglected for about half a century, when Julius II. resolved to carry out the building, and employed Bramanté, then celebrated as an architect, to make a new design. This design still exists. The foundation stone was laid, in 1506; and the works carried on with great activity till the death of the pope in 1513. Bramanté who died the following year, was succeeded by Baldassare Peruzzi.

Almost every architect who was employed during the long course of time required for the erection of this great edifice, proposed a new design. That of San Gallo, who succeeded Peruzzi, is one of the best, and is still preserved. It was not till his death in 1546, when the superintendence devolved on Michael Angelo, then seventy-two years of age, that much progress was made. He designed the dome; and had the satisfaction, before his death in his ninetieth year (1564), of seeing the most arduous part of the task completed; and he left such complete models of the remainder that it was carried out exactly in conformity with his design by his successors, Vignola and Giacomo della Porta, and successfully terminated by the latter in 1590 in the pontificate of Sixtus V. The design of Michael Angelo was in the form of a Greek cross, but the building was actually completed as originally designed by Bramanté as a Latin cross, under Paul V., by the architect Carlo Maderno. The portico and façade were also by him. He is much blamed for altering Michael Angelo's plan, because the result is that the projecting nave prevents the dome (the great part of the work) from being well seen. The façade is considered paltry, and too much cut up into small pieces. It is observable that this entrance façade is at the east end of the church, not the west, as it would certainly have been north of the Alps. But in Italy the principle of orientation was little regarded.

Maderno's nave was finished in 1612, and the façade in 1614, and the church dedicated by Urban VIII. in 1626. In the front of the portico, is a magnificent atrium in the form of a piazza, enclosed on two sides by grand semicircular colonnades. This was erected under Alexander VII. by the architect Bernini.

The façade of the cathedral is 368 feet long and 45 feet high. As already mentioned, the design is not generally approved, but some allowance must be made for the necessities of the case. The balconies in the front were required, as the pope, at Easter, always bestows his blessing on the people from them. Five open arches lead into a magnificent vestibule, 439 feet long, 47 feet wide, and 65 feet high, and adorned with statues and mosaics. Here is preserved a celebrated mosaic of St. Peter walking on the sea, called the *Naviella*, designed by Giotto in 1293, and preserved from the old basilica. The central bronze doors are also relics saved from the old church. On entering the interior of the cathedral,

its enormous size does not produce the impression its grandeur of proportions should do on the spectator. This arises from the details being all of an excessive size. The pilasters of the nave, the niches, statues, mouldings, &c., are all such as they might have been in a much smaller church, magnified. There is nothing to mark the scale, and give expression to the magnitude of the building. The figures supporting the holy water fountain, for example, appear to be those of cherubs of a natural size, but when more closely approached, turn out to be six feet in height, and the figures in the niches are on a still more colossal scale. The cathedral is 613 feet long, and 450 feet across the transepts. The arch of the nave is 90 feet wide, and 152 feet high. The diameter of the dome is 195½ feet. From the pavement to the base of the lantern is 405 feet, and to the top of the cross 434½ feet. The dome is thus 50 feet wider and 64 feet higher than that of St. Paul's (q. v.) in London.

The walls of the interior are adorned with plates of the richest marbles, and copies of the most celebrated paintings executed in mosaic. The arch piers have two stories of niches with statues of saints, but these unfortunately, are in a debased style of art. The pavement is all in marbles of different colors, arranged in beautiful patterns designed by Giacomo della Porta. The dome is, however, the finest part of the cathedral; it is supported on four great arches. Immediately under the dome stands the high altar over the grave of St. Peter. It is surmounted by a magnificent baldacchino or canopy, in bronze, which was designed by Bernini in 1633, and executed with bronze stripped from the Pantheon by Pope Urban VIII. Beneath the high altar is the shrine, in which 112 lamps burn day and night. The building is adorned with many remarkable monuments and statues, some of them by Michael Angelo, Canova and Thorwaldsen. The most of the monuments are erected in memory of the popes, but there is one to 'James III., Charles III., and Henry IX., kings of England,' the remains of the exiled Stuarts being buried in the vaults beneath. The 'Grotte Vaticane,' or crypt, has been most carefully and religiously preserved during all the changes and works of the cathedral; so much so, that the ancient pavement remains undisturbed.

As a work of architectural art, St. Peter's is the greatest opportunity which has occurred in modern times; but, notwithstanding the great names of the men who were engaged upon the work, it is universally admitted to be a grand and lamentable failure.

PETER'S, ST., COLLEGE, Cambridge, commonly called Peter-house, was founded before any other college now existing in England—viz., in 1257, by Hugh de Balsham, Bishop of Ely, and was endowed by him in 1282, with a maintenance for a master and 14 fellows. In addition to the 14 original foundation-fellows, there are two bye-fellows on different foundations, and 23 scholars. The master is elected by the society.

PETERSBURG, a city and port of entry of Virginia, U.S., on the south bank of the Appomatox River, 12 miles above its junction with James River, at City Point. It is 23 miles south of Richmond. Five railways contribute to make it the third city in the state in respect of population, and connect it with Baltimore, Wilmington (N. C.), Norfolk, Richmond, Mobile, &c. P. is well built. It contains churches of the Presbyterians, Methodists, Episcopalians, Baptists, and Catholics. There are here several cotton and woollen factories, forges, and numerous mills to which the falls in the river furnish extensive power. In the campaign of 1864, Lieutenant-General Grant, commander of the Federal army, failing to take Richmond, besieged P., and was repulsed in several attacks by General Beauregard, with heavy loss. Pop. (1880) 21,656.

PETERSBURG, ST. See **ST. PETERSBURG**.

PETERSFIELD, a parliamentary borough and market-town in Hampshire, 23 miles east-north-east of Southampton, and 55 south-west of London by railway. It is a pleasant country-town, and contains a Norman parish chapel of the 12th c., and an educational institution, called Church's College. An equestrian statue of William III., once richly gilt, stands in the market-place. P. returns a member to the House of Commons. Pop. (1871) 6104; (1881) 6546.

PETERWA'RDEIN, a town in the Austrian province of Croatia and Slavonia, and one of the strongest fortresses in the Austrian dominions, is situated in a marshy, unhealthy locality on the right bank of the Danube, 50 miles north-west of Belgrade. The ordinary garrison is a very strong one, and besides it, the town and suburbs contain a population of (1869) 4022, mostly Germans. The most ancient part of the fortifications, the Upper Fortress, is situated on a rock of serpentine, which on three sides rises abruptly from the plain. P., situated on a narrow peninsula formed by a loop of the Danube, occupies the site of the Roman *Acumincum* (*acumen*, point), and is said to have been named in honor of Peter the Hermit, who marshalled here the soldiers of the first crusade. In 1688, the fortifications were blown up by

the imperialists, and the town was soon after burned to the ground by the Turks; but at the Peace of Passarowitz, on 21st July 1718, it remained in the possession of the emperor. It was here that, on 5th August, 1716, Prince Eugene obtained a great victory over the Grand Vizier Ali.

PETIOLE. See **LEAVES**.

PÉTION DE VILLENEUVE, JÉRÔME, noted for the part he played in the first French Revolution, was the son of a procurator at Chartres, and was born there in 1758. He was practising as an advocate in his native city, when he was elected in 1789 a deputy of the *Tiers Etat* to the States-General. His out-and-out republican principles, and his facile oratory, sonorous rather than eloquent, quickly made him popular, though he had an essentially mediocre understanding, and was altogether a windy, verbose personage. He was a prominent member of the Jacobin Club, and a great ally of Robespierre; the latter was called the 'Incorruptible,' and P. the 'Virtuous.' He was sent along with Barnave and Latour-Maubourg to bring back the fugitive royal family from Varennes, and in the execution of this commission he acted in an extremely unfeeling manner.

He afterwards advocated the deposition of the king, and the appointment of a popularly elected regency, and along with Robespierre received, 30th September 1791, the honors of a public triumph. On the 18th of November he was elected *Maire de Paris* in Bailly's stead, the court favoring his election, to prevent that of Lafayette. In this capacity he encouraged the demonstrations of the lowest classes, and the arming of the populace. But as the catastrophe drew near, he awoke to a sense of the terrible nature, and sought in vain to arrest the torrent. On the triumph of the Terrorists, P.'s popularity declined, and he joined the Girondists. On the king's trial, he voted for death, but with delay of execution and appeal to the people, upon which he became suspected of being a royalist, and of partaking in the treason of Dumouriez. He was thrown into prison, 2d June 1793, on the fall of the Gironde, but escaped from prison, and joined the other Girondists at Caen. Upon the defeat of their army by that of the Convention, he fled, in July 1793, into Bretagne, and in company with Buzot reached the neighborhood of Bordeaux, which, however, had already submitted. A short time after, P.'s and Buzot's corpses were found in a corn-field near St. Emilion, partly devoured by wolves. They were supposed to have died by their own hands. P.'s character has been defended by Madame de Genlis and Madame Roland. It appears that he was extremely virtuous in all his domestic relations; but, on the other hand, his public career shows him to have been weak, shallow, ostentatious, and vain. *Les Œuvres de Pétion*, containing his speeches, and some small political treatises, were published in 1793.

PETITIO PRINCIPII ('a begging of the principle or question') is the name given in Logic to that species of vicious reasoning in which the proposition to be proved is assumed in the premises of the syllogism.

PETITION (Lat. *peto*, I ask), a supplication preferred to one capable of granting it. The right of the British subject to petition the sovereign or either House of Parliament for the redress of grievances is a fundamental principle of the British constitution, and has been exercised from very early times. The earliest petitions were generally for the redress of private wrongs, and the mode of trying them was judicial rather than legislative. Receivers and triers of petitions were appointed, and proclamation was made inviting all persons to resort to the receivers. The receivers, who were clerks or masters in Chancery, transmitted the petitions to the triers, who were committees of prelates, peers, and judges, who examined into the alleged wrong, sometimes leaving the matter to the remedy of the ordinary courts, and sometimes transmitting the petition to the chancellor or the judges, or, if the common law afforded no redress, to parliament. Receivers and triers of petitions are still appointed by the House of Lords at the opening of every parliament, though their functions have long since been transferred to parliament itself. The earlier petitions were generally addressed to the House of Lords; the practice of petitioning the House of Commons first became frequent in the reign of Henry IV.

Since the Revolution of 1688, the practice has been gradually introduced of petitioning parliament, not so much for the redress of specific grievances, as regarding general questions of public policy. Petitions must be in proper form and respectful in language; and there are cases where petitions to the House of Commons will only be received if recommended by the crown, as where an advance of public money, the relinquishment of debts due to the crown, the remission of duties payable by any person, or a charge on the revenues of India have been prayed for. The same is the case with petitions praying for compensation for losses out of the public funds. A petition must, in ordinary cases, be presented by a member of the House to which it is addressed; but petitions from the corporation of London may be presented by the sheriffs or lord mayor. Petitions from the cor-

poration of Dublin have also been allowed to be presented by the lord mayor of that city, and it is believed that a similar privilege would be acceded to the lord provost of Edinburgh.

The practice of the House of Lords is to allow a petition to be made the subject of a debate when it is presented; and unless a debate has arisen on it, no public record is kept of its substance, or the parties by whom it is signed. In the House of Commons, petitions not relating to matters of urgency are referred to the Committee on Public Petitions, and in certain cases ordered to be printed.

In the five years ending 1843, the number of petitions presented to the House of Commons was 70,072; in the five years ending 1872, 101,573.

PETITION OF RIGHTS, a declaration of certain rights and privileges of the subject obtained from King Charles I. in his third parliament. It was so called because the Commons stated their grievances in the form of a petition, refusing to accord the supplies till its prayer was granted. The petition professes to be a mere corroboration and explanation of the ancient constitution of the kingdom; and after reciting various statutes, recognizing the rights contended for, prays 'that no man be compelled to make or yield any gift, loan, benevolence, tax, or such like charge, without common consent by act of parliament; that none be called upon to make answer for refusal so to do; that freemen be imprisoned or detained only by the law of the land, or by due process of law, and not by the king's special command, without any charge; that persons be not compelled to receive soldiers and mariners into their houses against the laws and customs of the realm; that commissions for proceeding by martial law be revoked.' The king at first eluded the petition, expressing in general terms his wish that right should be done according to the laws, and that his subjects should have no reason to complain of wrongs or oppressions; but at length, on both Houses of Parliament insisting on a fuller answer, he gave an unqualified assent on the 26th of June 1628.

PETŐFI, SANDOR (ALEXANDER), who may fairly be described as the national poet of Hungary, was born at Little Körös, in the county of Pesth, in 1823. His father was a butcher, and a small landowner in Little Kumania, and bore the name of Petrovich (son of Peter)—a name indicating a Slavonic origin, which the poet, when he came to manhood, exchanged for the Magyar equivalent, Petőfi. In 1838, his father was reduced to poverty by an overflowing of the Danube, which destroyed his little estate; and it was by the help of relatives that he was able to carry out his design of educating his son for a profession. P. was sent to the lyceum of the town of Schemnitz. It was while there that he began to write verses, and first displayed the extravagant fondness for theatricals which characterized him throughout life. From the first, he neglected his studies; ultimately, he ran away with a band of German strollers. His father after some time found him out, and brought him home, and he remained for a period in quasi-custody among his relatives. When at length he was again sent to school at Oedenburg, he almost immediately ran away, and enlisted as a common soldier. After he had been about two years in the army, a physician, who had taken pity upon him, procured his discharge, and he went back to his relations. He afterwards went to Pápa, to complete his education. His passion for the stage, however, drew him away from Pápa, as it had formerly done from Schemnitz; in 1842, he left it to join a troop of comedians. His stage-attempts were utter failures, and he soon parted from the comedians, if, indeed, he was not dismissed by them. He made his way to Presburg, and afterwards to Pesth, where he got some employment as a translator from the English and the French.

Among other works, he translated a novel by Mr. G. P. R. James. As soon as his literary labor supplied him with the means of traveling, his passion for the stage returned upon him; he went to Debreczin, and made another venture as an actor—playing the part of Othello—but failed even more completely than before. At last he had the good fortune to be invited to contribute to a newspaper at Pesth—the *Devallop*—and he immediately closed with the proposal. He made his way on foot from Debreczin to Pesth—a distance of nearly 200 miles—wearing shoes padded with straw, and carrying in his bosom a MS. volume of verses, his whole provision for the journey consisting of two florins, which he got from an old school-fellow. It was on his arrival at Pesth that he exchanged the name of Petrovich for Petőfi. Within a few weeks of his arrival, he had troops of friends and a reputation.

He introduced himself to Vörösmarti, then the most popular poet of Hungary, who received the shabbily-dressed stranger coldly, and did not readily consent to listen to his verses. But when he had listened, he expressed his admiration warmly. 'Hungary,' he exclaimed, 'never had such lyrics: you must be cared for.' And from that time, he treated P. as a son, and never rested until his merits were fully acknowledged by his

countrymen. P. was almost at once received into the Literary National Circle, at the expense of which was published his *Versek*, which appeared in 1844. This was soon followed by other volumes, which succeeded each other with amazing rapidity; all of them, though regarded as vulgar by some of the critics, obtaining an unbounded popularity; so that it was said of P. that 'he never went to bed at night, he never arose in the morning, without hearing his songs from the multitudinous passengers in the public streets.' He sprang almost at a bound into a position in Hungary similar to that which Burns holds in Scotland—that at once of the greatest poet and the representative man of his country.

In 1848, when the revolutionary movement which spread over Europe, began to affect the Hungarians, his energies and enthusiasm found a more useful direction; he became, by speech and pen, the advocates of the independence of Hungary. He was for some time a member of the Diet, but in October 1848, he became a captain in the Hungarian army; and in the beginning of 1849, he was appointed adjutant and secretary to General Bem. He was present at the battle of Segesvár, fought on July 31, 1849, in which Bem's army was defeated with great slaughter; and he was never heard of after that battle. It is believed that he was trampled to death in the flight, and that his body, so defaced as to escape recognition, was buried with the multitude of Magyar dead left upon the field. His countrymen long believed that he was not dead, but a prisoner in an Austrian dungeon; and it is said that among the peasantry this belief is cherished still. Several false Petőfis have made their appearance since his death, and much spurious poetry has been published under his name. Lately, however, his countrymen have subscribed for the erection of a monument to his memory, and have purchased, with a view to its preservation, the house in which he was born at Little Körös. He left a widow—who married again—and one son. His brother, STEPHEN, has gained some reputation as a poet.

His poems, 1775 in number, were published in ten volumes. Most of them are lyrics, of which he published several collections, under the titles, *Oppress Leaves on Bletka's Grave*; *Pearls of Love*; *Starless Nights*; *Clouds*. The most celebrated of his narrative poems—also the longest—are, *Janos, the Hero*; and *Istok, the Fool*. His earliest work was *The Village Hammer*, published in 1843; his latest, *The Assessor of the Judgment-seat*, which appeared in 1849. A volume, containing a poem entitled *The Apostle*, was suppressed by the Austrian government after the pacification of Hungary. P. published a novel, *The Hangman's Rope*, which was by no means successful, and several volumes of tales, criticisms, and sketches of travels; and he translated largely from English and French into the Magyar.

A selection from his earlier pieces, translated into German, was published in 1845; and several volumes of translations from his writings have since appeared in Germany. They have also been translated into French, Flemish, Polish, Danish, and Italian; and an English version, comprising his finest poems, was published in 1866 by Sir John Bowring. The quality of his poetry has been as fully recognized among foreigners as among his countrymen: thus, Grimm declared that 'Petőfi will rank among the very greatest poets of all times and tongues;' Henry Heine spoke rapturously of his 'rustic song, sweeter than that of the nightingale;' and Uhland avowed that only old age could prevent his learning Magyar, that he might enjoy P. in his native dress.

PE'TRA (Heb. SELA, both names signify 'Rock') was anciently the capital of the Nabathæans, and was situated in the 'desert of Edom' in Northern Arabia, about 72 miles north-east of Akabah—a town at the head of the Gulf of Akabah, an arm of the Red Sea. It occupied a narrow rocky valley overhung by mountains, the highest and most celebrated of which is Mount Hor, where Aaron, the first Hebrew high-priest, died, and was thus in the very heart of the region hallowed by the forty years' wanderings of the Israelites. The aboriginal inhabitants were called *Horim* ('dwellers in caves'). It was then conquered by the Edomites or Idumeans (but it never became their capital); and, in the 3d or 4th c. B.C., it fell into the hands of the Nabathæans, an Arab tribe, who carried on a great transit-trade between the eastern and western parts of the world. It was finally subdued by the Romans in 105 A.D., and afterwards became the seat of a metropolis; but was destroyed by the Mohammedans, and for 1200 years its very site remained unknown to Europeans. In 1812, Burckhardt first entered the valley of ruins, and suggested that they were the remains of ancient Petra. Six years later, it was visited by Messrs. Irby, Mangles, Banks, and Leigh, and in 1823 by M.M. Laborde and Linant, and since then by numerous travelers and tourists to the East, as Bartlett, Porter, and Dean Stanley.

Laborde's drawings give us a more vivid impression of the ruins of P. than any descriptions, however picturesque. These ruins stand in a small open irregular basin, about half a mile square, through which runs a brook, and are best approached by

an extraordinary chasm or ravine, called the Sik, narrowing as it proceeds till in some places the width is only 12 feet, while the rocky walls of red-sandstone tower to the height of 300 feet. Hardly a ray of light can pierce this gloomy gorge, yet it was once the highway to P., and the remains of an ancient pavement can be traced beneath the brilliant oleanders that now cover the pathway. All along the face of the rocky walls are rows of cave-tombs, hewn out of the solid stone, and ornamented with façades. These are also numerous elsewhere. Originally, they were probably dwellings of the living, not of the dead—a supposition justified by an examination of their interior; but when the Nabathæans built the city proper in a little basin of the hills, they were in all likelihood abandoned, and then set apart as the family-sepulchres of those who had formerly been 'dwellers in the clefts of the rocks.' The principal ruins are—1. *El-Khuzneh* ('the

securty still hangs over his relation to this lady, but it is almost certain that she was no less a paragon of virtue than of loveliness. He met her on the 6th of April 1327 in the church of St. Clara in Avignon, and at once and for ever fell deeply in love with her. The lady was then 19, and had been married for two years to a gentleman of Avignon, named Hugues de Sade.

For ten years, P. lived near her in the papal city, and frequently met her at church, in society, at festivities, &c. He sung her beauty and his love in those sonnets whose mellifluous conceits ravished the ears of his contemporaries, and have not yet ceased to charm. Laura was not insensible to a worship, which made an emperor (Charles IV.) beg to be introduced to her, and to be allowed to kiss her forehead; but she seems to have kept the too-passionate poet at a proper distance. Only once did he dare to make an avowal of his love in her presence, and then he was

sternly reproved. In 1338, P. withdrew from Avignon to the romantic valley of Vaucluse, where he lived for some years, spending his time almost solely in literary pursuits. A most brilliant honor awaited him at Rome, in 1341, where, on Easter-day, he was crowned in the Capitol with the laurel-wreath of the poet. The ceremonies which marked this coronation were a grotesque medley of pagan and Christian representations. P. was, however, as ardent a scholar as he was a poet; and throughout his whole life, he was occupied in the collection of Latin MSS., even copying some with his own hand. To obtain these, he traveled frequently throughout France, Germany, Italy, and Spain. His own Latin works were the first in modern times in which the language was classically written. The principal are his *Epistola*, consisting of letters to his numerous friends and acquaintances, and which rank as the best of his prose works; *De Vitis Virorum Illustrum*; *De Remediis utriusque Fortunæ*; *De Vita Solitaria*; *Rerum Memorandarum Libri IV.*; *De Contemptu Mundi*, &c. Besides his prose-epistles, P. wrote numerous epistles in Latin verse, eclogues, and an epic poem called *Africa*, on the subject of the second Punic War. It was this last production which obtained for him the laurel-

Petra—Mount Seir —From Laborde.

Treasure-house'), believed by the natives to contain, buried somewhere in its sacred enclosure, the treasures of Pharaoh. It directly faces the mouth of the gorge we have described, and was the great temple of the Petæans. 2. *The Theatre*, a magnificent building, capable of containing from 3000 to 4000 spectators. 3. *The Tomb with the Triple Range of Columns*. 4. *The Tomb with Latin Inscription*. 5. *The deer or Convent*, a huge monolithic temple hewn out of the side of a cliff, and facing Mount Hor. 6. *The Arcopolis*. 7. *Kusr Farôn*, or Pharaoh's palace, the least incomplete ruin of Petra. Most of the architecture is Greek, but there are also examples of the influence of Egypt, pyramidal forms being not unknown.

PETRARCA, FRANCESCO, the first and greatest lyric poet of Italy, was the son of a Florentine notary named Petracco, who belonged to the same political faction as the poet Dante, and went into exile along with him and others in 1302. Petracco took up his residence at Arezzo, and here the future poet was born in the month of July 1304. His original name was Francesco di Petracco, which he subsequently changed to that by which he is now known. When P. was about eight years of age, his father removed to Avignon, where the papal court was then held; and here, and at the neighboring town of Carpentras, the youth studied grammar, rhetoric, and dialectics. Contrary to his own inclination, but in compliance with the wish of his father, he spent seven years in the study of law at Montpellier and Bologna; but in 1326 his father died, and P. now devoted himself partly to the gaieties of Avignon, and partly to classical studies, or rather to the study of the Latin classics, as it was only towards the end of his life that he attempted to master Greek. At this time, he ranked among his friends, the jurist Soranzo, John of Florence, the apostolic secretary, Jacopo Colonna, Bishop of Lombes in Gascony, and his brother, the Cardinal Giovanni, Azzo da Corregio, lord of Parma, and many other noble and learned personages. His illustrious admirers—among whom were emperors, popes, doges, kings, and sovereign-dukes—obviously thought themselves honored by their intimacy with the son of a poor notary, and some were even forward in proffering him their favor. But the great event in P.'s life (viewed in the light of its literary consequences) was his tenderly romantic and ultimately pure passion for Laura—the golden-haired, beautiful Frenchwoman. Some slight ob-

wreath at Rome.

P., it may be mentioned, displayed little solicitude about the fate of his beautiful Italian verse, but built his hope of his name being remembered on his Latin poems, which, it has been said, are now only remembered by his name. In 1353 he finally left Avignon, and passed the remainder of his life in Italy—partly at Milan, where he spent nearly ten years, and partly at Parma, Mantua, Padua, Verona, Venice, and Rome. At last, in 1370, he removed to Arquà, a little village prettily situated among the Euganean Hills, where he spent his closing years in hard scholarly work, much annoyed by visitors, troubled with epileptic fits, not overly rich, but serene in heart, and displaying in his life and correspondence a rational and beautiful piety. He was found dead in his library on the morning of the 18th July 1374, his head dropped on a book!—P. was not only far beyond his age in learning, but had risen above many of its prejudices and superstitions. He despised astrology, and the childish medicine of his times; but, on the other hand, he had no liking for the conceited scepticism of the medieval *savants*; and, in his *De sui Ipsius et multorum aliorum Ignorantia*, he sharply attacked the irreligious speculations of those who had acquired a shallow free-thinking habit from the study of the Arabico-Aristotelian school of writers, such as Averrhoes. P. became an ecclesiastic, but was contented with one or two inconsiderable benefices, and refused all offers of higher ecclesiastical appointment.—The Italian lyrics of P.—the chief of which are the *Rime* or *Canzoniere*, in honor of Laura—have done far more to perpetuate his fame than all his other works. Of Italian prose, he has not left a line.

The *Rime*, consisting of sonnets, canzonets, madrigals, were composed during a period of more than forty years; and the later ones—in which P.'s love for Laura, long since laid in her grave, appears purified from all earthly taint, and beautiful with something of a beatific grace—have done as much to refine the Italian language as the *Divina Commedia* of Dante. Of his *Rime*, there have been probably more than 300 editions; the first that of Venice, 1470; the most accurate, that by Marsand (Padua, 1819; Eng. trans. by Macgregor, (1851). Collective editions of his works have been published (Basel, 1495, 1554, and 1581 *et seq.*). Of numerous lives of him the principal are those of Bellutello, De Sades, Tiraboschi, Ugo Foscolo, and Geiger (1874); in Eng. Campbell (1841); Reeve in *Modern Classics for Eng. Readers* (1876).

PETREL (*Procellaria*), a genus of birds, sometimes ranked among *Larida* (q. v.), and sometimes constituted into a separate family, *Procellariida*, which is now subdivided into several genera, and distinguished by having the bill hooked at the tip, the extremity of the upper mandible being a hard nail, which appears as if it were articulated to the rest, the nostrils united into a tube which lies along the back of the upper mandible, and the hind-toe merely rudimentary. They possess great power of wing, and are among the most strictly oceanic of birds, being often seen at great distances from land. Among the *Procellariida* are reckoned the Fulmars (q. v.), Shearwaters (q. v.), &c., and the small birds designated **PETRELS**, of which the Stormy Petrel is a familiar example. These form the genus *Thalassidroma* of recent ornithological systems, the name (Gr. sea-runner) being given to them in allusion to their apparent running along the surface of the waves, which they do in a remarkable manner, and with great rapidity, particularly when the sea is stormy, and the molluscs and other animals forming their food are brought in abundance to the surface—now descending into the very depth of the hollow between two waves, now touching their highest foamy crests, and flitting about with perfect safety and apparent delight. Hence also their name Petrel, a diminutive of Peter, from the apostle Peter's walking on the water.

From the frequency with which flocks of these birds are seen in stormy weather, or as heralds of a storm, they are very unfavorably regarded by sailors. They have very long and pointed wings, passing beyond the point of the tail; and the tail is square in some, slightly forked in others. Their flight much resembles that of a swallow. They are to be seen in the seas of all parts of the world, but are more abundant in the southern than in the northern hemisphere. The names Stormy P. and Mother Carey's Chicken are sometimes more particularly appropriated to *Thalassidroma pelagica*, a bird scarcely larger than a lark, and the smallest web-footed bird known, of a sooty black color, with a little white on the wings and some near the tail. Two or three other species are occasionally found on the British shores; one of which, the Fulmar P., breeds on the rocks of the Scilly Isles, St. Kilda, the Orkneys, Shetland Isles, &c. Like many others of the family, it generally has a quantity of oil in its stomach, which, when wounded or seized, it discharges by the mouth or nostrils; and of this the people of St. Kilda take advantage, by seizing the birds during incubation, when they sit so closely as to allow themselves to be taken with the hand, and collecting the oil in a vessel.

PETRIFACTION, a name given to organic remains found in the strata of the earth, because they are generally more or less mineralized or made into stone. The word has fallen very much into disuse, having given place to the terms Fossil (q. v.) and Organic Remains.

PETROCA, a genus of birds of the family *Sylviadae*, natives of Australia, nearly allied to the Redbreast, and to which its familiar name *Robin* has been given by the colonists. The song, call-note, and manners of *P. multicolor*, a species abundant in all the southern parts of Australia, very much resemble those of the European bird, but its plumage is very different: the male having the head, throat, and back jet-black, the forehead snowy-white, one longitudinal and two oblique bands of white on the wings, and the breast bright scarlet; the female is brown, with red breast. There are several other species, birds of beautiful plumage.

PETROLEUM. See **NAPHTHA**. In consequence of the danger attending the storing and keeping of petroleum, an act of parliament was passed in 1861 (25 and 26 Vict. c. 66) to regulate the subject, putting it on a similar footing to gunpowder. A license is required to keep large quantities, which is obtained in England from the aldermen of the city of London, the metropolitan board, the mayor and aldermen of boroughs, or the harbor commissioners, according to the locality where it is proposed to be kept; and in other places, in England and Scotland, from two justices of the peace. If the license is refused, the party may appeal to the Home Secretary. Not more than forty gallons must be kept within fifty yards of a dwelling-house or a warehouse for goods, except in pursuance of a license, under a penalty of £20 per day. One moiety of the penalty is given to the informer. A search-warrant may be obtained from justices, in case it is suspected that the act is violated.

PETROLOGY (Gr. science of rocks), a term recently introduced into geology to designate particular aspects of the study of rocks, apart from their organic contents. By some, it is confined to an examination of their structure and composition; by others, it is extended to the study of rock-masses, their planes of division, their forms, their position and mutual relations, and other characters not bearing on the question of the geological time of their production.

PETROMYZON. See **LAMPREY**.

PETRONEL, an ancient and clumsy description of pistol.

PETRONIUS, C., a Roman voluptuary at the court of Nero, whose profligacy is said to have been of the most superb and elegant description. We know, however, very little about him. He was at one time proconsul of Bithynia, was subsequently appointed consul, and is certified as having performed his official duties with energy and prudence. But his grand ambition was to shine as a court-exquisite. He was a kind of Roman *Brummell*, and Nero thought as highly of him as did the Prince Regent of the famous Beau. He was entrusted by his imperial master and companion with the charge of the royal entertainments, and thus obtained (according to Tacitus) the title of *Arbiter Elegantiae*. Nero would not venture to pronounce anything *comme il faut*, until it had received the approval of the oracle of Roman fashion. The influence which he thus acquired was the cause of his ruin. Tigellinus, another favorite of Nero, conceived a hatred of P., brought false accusations against him, and succeeded in getting his whole household arrested.

P. saw that his destruction was inevitable, and committed suicide (66 B.C.), but in a languid and graceful style, such, he thought, as became his life. He opened some veins, but every now and then applied bandages to them, and thus stopped the flow of blood, so that he was for a while enabled to gossip gaily with his friends, and even to appear in the streets of Cumæ before he died. We are told that he wrote, sealed, and despatched to Nero, a few hours before his death, a paper containing an account of the tyrant's crimes and flagitious deeds. It has been generally supposed that P. is the author of a well-known work entitled, in the oldest MSS., *Petronii Arbitri Satyricon*, a series of fragments belonging apparently to a very extensive comic novel or romance (see **NOVELS**), the greater portion of which has perished, but there is really no satisfactory evidence to show whether or not he was so. It is probable, however, that the work belongs to the 1st c. A.D. The fragments exhibit a horrible picture of the depravity of the times; but there is no indication that the author disapproves of what he describes. The *editio princeps* of the fragments appeared at Venice in 1499; later editions are those of Burmann (Traj. ad. Rhen. 1709; 2d. edit. Amst. 1748), and of Antonius (Leip. 1781).

PETROPOL'VSK, a town of Asiatic Russia, in the province of Akmoinsk, on the river Ishim, 175 m. W.N.W. of Omsk. Pop. (1867) 8220. It is an important military station, and has a cannon-foundry. A large trade is carried on.—P. is also the name of a small port of Russian Siberia, near the mouth of the river Avatcha. Pop. (1867) 479.

PETRO'VSK, a town of Russia, in the province of Saratov, 55 miles north-west of Saratov, situated on the Medveditsa, a tributary of the Don. Pop. (1880) 11,000.

PETROZAVODSK, an important mining-town in the north of European Russia, capital of the government of Olonetz, stands on the western shore of Lake Onega, 300 miles by water north-east of St. Petersburg. A cannon-foundry was erected here in 1701 by Peter the Great, who himself had discovered the rich resources of this northern region in iron and copper ores. The town itself dates from the year 1708; and from that to the present time it has been the great center of the mining industry of the government. The Alexandrovsky arms-factory is specially deserving of notice. It was founded in 1773, and, besides other arms, it has produced many thousand pieces of cast-iron ordnance. Works are also fitted up for the preparation of steel. Wood abounds in the vicinity, and there is easy communication by water with St. Petersburg. Pop. (1867) 10,910.

PETSH, or **IPEK** (i. e., silk), a town of European Turkey, in Albania, stands on the Bistritza, or White Drin, 70 miles north-east of Scutari. It is a pleasant town; the houses are large and handsome, and, as a rule, have gardens attached, in which fruit and mulberry-trees are cultivated. Water, from the river, is led up into all the houses. Silk is extensively made, tobacco and fruits are largely cultivated, and arms manufactured. P. was formerly the residence of the Servian patriarchs. Pop. upwards of 16,000.

PETTY BAG OFFICE, one of the branches of the Court of Chancery, was abolished in 1874, and its duties were transferred. The clerk of the petty bag, an officer appointed by the Master of the Rolls, drew up writs of summons to parliament, *Comptes d'élire* for bishops, writs of *Scire facias*, and all original writs. A great deal of miscellaneous business was also transacted in the petty bag office, which the Lord Chancellor and Master of the Rolls were empowered to regulate and transfer from time to time. By the Act of 37 and 38 Vict. c. 81, these various duties have devolved on the Clerk of the Crown in Chancery, and on officers of the Supreme Court.

PETTY OFFICERS, in the royal navy, are an upper class of seamen, analogous to the non-commissioned officers in the army. They comprise the men responsible for the proper care of the several portions of the ship, the foremen of artificers, the signal-

men, and many others. They are divided into three classes: chief petty officers, at 2s. 6d. to 6s. a day; first-class working petty officers, at 2s. 2d. a day; and second-class working petty officers at 2s. a day. Petty officers are appointed and can be degraded by the captain of the ship. Her efficiency much depends on this useful class of sailors.

PETTY SESSIONS is the court constituted by two or more justices of the peace in England, when sitting in the administration of their ordinary jurisdiction. Though for many purposes statutes enable one justice to do acts auxiliary to the hearing and adjudication of a matter, yet the jurisdiction to adjudicate is generally conferred upon the justices in petty sessions, in which case there must be at least two justices present, and this is called a petty sessions, as distinguished from quarter sessions, which generally may entertain an appeal from petty sessions. For the purpose of securing always sufficient justices, the whole of the counties of England are subdivided into what are called petty sessional divisions, those justices who live in the immediate neighborhood being the members who form the court of such division. This subdivision of counties is confirmed by statute, and the justices at quarter sessions have power from time to time to alter it. Each petty sessions is held in some town or village which gives it a name, and a police-court or place is appropriated for the purpose of the sittings of the court. There is a clerk of each petty sessions, usually a local attorney, who advises the justices, and issues the summons and receives the fees made payable for steps of the process. The justices in petty sessions have a multifarious jurisdiction, which they exercise chiefly by imposing penalties authorized by various acts of parliament, as penalties against poachers, vagrants, absconding workmen and apprentices, &c. They also have jurisdiction to hear charges for all indictable offences, to take depositions of witnesses, and, if they think a case of suspicion is made out, to commit the party for trial at the quarter sessions or assizes, and to bind over the witnesses to attend. See also **JUSTICE OF THE PEACE**.

PETUNIA, a genus of plants of the natural order *Solanaceae*, natives of the warmer parts of America. They are herbaceous plants, very nearly allied to Tobacco, and with a certain similarity to it in the general appearance of the foliage, which has also a slight viscidness, and emits when handled a disagreeable smell, but the flowers are very beautiful, and varieties improved by cultivation are amongst the favorite ornaments of our greenhouses and flower-borders. The petunias, although perennial, are very often treated as annuals, sown on a hot-bed in spring, and planted out in summer, in which way they succeed very well even in Scotland. They are tall plants, with branching weak stems, and may readily be made to cover a trellis. Although, when treated as greenhouse plants, they become half-shrubby, they do not live more than two or three years. The name *P.* is from the Brazilian *Petun*. The first *P.* was introduced into Britain in 1825.

PETUNTZE, a white earth used by the Chinese in the manufacture of porcelain, and said to consist of comminuted but undecomposed felspar. It is fusible, and is used for glazing porcelain.

PE'TWORTH, or **SUSSEX MARBLE**, is a thin layer of limestone, composed of the shells of fresh-water *Paludinae*. It has been long, but not extensively used for ornamental purposes. A polished slab of it was found in a Roman building at Chichester, and pillars formed of it exist in the cathedrals of Chichester and Canterbury.

PEUTINGERIAN TABLE, the name given to a most interesting ancient document, which exhibits the military roads of the Roman Empire, and indeed of the world known to the Romans. It is not, properly speaking, a map; no regard being paid to geographic position, or the extent of countries. The great lines of road are laid down in a narrow strip, as if nearly parallel, all proceeding from Rome as a center; and as to rivers, it only appears whether they cross the road from left to right or from right to left of the traveler proceeding from Rome. The Mediterranean and other seas are represented by mere narrow channels. A small house is the mark for a town; important towns and military stations are distinguished by walls and towers. Rome, Constantinople, and Antioch are each represented by a circle, within which is a human figure seated; in the case of Rome, the figure is crowned. Until very recently, a portion of the only copy of this valuable relic of antiquity known to exist was evidently wanting, as it terminated abruptly on the west at the confines of Spain, and included only the eastern parts of Britain. In the east, it traces roads through India to a number of places of trade as far as the mouth of the Ganges. It is on parchment, and as described in all the publications devoted to it, twenty-one feet in length, and about one foot wide. It was found in the library of the Benedictine monastery at Tegernsee, in Upper Bavaria, in the 15th c., by Conrad Celtes, who bequeathed it to Conrad

Peutingier of Augsburg, a zealous antiquary, and one of the earliest authors on the Roman and other antiquities of Germany. Peutingier began to prepare a copy of it for publication, but died before he could accomplish his purpose, which, however, was partially executed by Mark Welser, in his *Fragmenta Tabulae Antiquae ex Peutingeriorum Bibliotheca* (Venice 1591).

The ancient document itself remained in the hands of the Peutingier family and attracted no further notice, till it was offered for sale in 1714, and purchased by Prince Eugene, who presented it to the Imperial Library of Vienna, in which it still remains. An exact copy of it was published at Vienna in 1753, with an introduction and index by F. C. von Scheyb. It was again published as an appendix to Katancsich's *Orbis Antiquus* (Ofen. 1825); and at the request of the Academy of Munich, a revised edition, with an introduction, was published by Conrad Mannert (Leip. 1824). Since that time, a leaf detached from the rest has been found in the Imperial Library at Vienna, but we are not aware that any particular account of it or its contents has yet been given to the public.

The Peutingerian Table does not always agree with the Antonine Itinerary (see **ITINERARY**); some stations and towns being marked in the one which are not in the other, the distances marked being also sometimes different. But the two together throw great light on ancient geography. It appears almost certain from internal evidence that the Peutingerian Table belongs to the third century of the Christian era, or the beginning of the fourth, although the existing copy seems to belong to a later date. The general character of the work seems to show that its authorship is to be referred to times of prevalent paganism; whilst a few things appear, probably alterations or insertions of a copyist, which refer to Christianity.

PEWS (anciently *pues*; Old Fr. *puyis*; Dutch *puyes*; Lat. *podium*, 'anything on which to lean'; *s'appuyer*), enclosed seats in churches. Church-seats were in use in England some time before the Reformation, as is proved by numerous examples still extant, the carving on some of which is as early as the Decorated Period, i. e., before 1400 A.D.; and records as old as 1450, speak of such seats by the name of *pues*. They were originally plain fixed benches, all facing east, with partitions of wainscoting about three feet high, and sides of the width of the seat, panelled or carved; the sides sometimes rising above the wainscoting, and ending in finials or poppies, or else ranging with it and finished with a moulding. After the Reformation, probably under the influence of the Puritans, who, objecting to some parts of the service which they were compelled to attend, sought means to conceal their nonconformity, pews grew into large and high enclosures, containing two or four seats, lined with baize, and fitted with doors, desks, and cushions. Pews were early assigned to particular owners, but at first only to the patrons of churches. A canon made at Exeter in 1287, rebukes quarrelling for a seat in church, and decrees that none shall claim a seat as his own except noblemen and the patrons. Gradually, however, the system of appropriation was extended to other inhabitants of the parish, to the injury of the poor, and the multiplication of disputes.

The law of pews in England is briefly this. All church-seats are at the disposal of the bishop, and may be assigned by him, either (1) directly by faculty to the holders of any property in the parish; or (2) through the churchwardens, whose duty it is, as officers under the bishop, to 'seat the parishioners according to their degree.' In the former case, the right descends with the property, if the faculty can be shown, or immemorial occupation proved. In the latter, the right can at any time be recalled, and lapses on the party ceasing to be a regular occupant of the seat. It appears that by common law every parishioner has a right to a seat in the church, and the churchwardens are bound to place each one as best as they can. The practice of *letting* pews, except under the church-building acts, or special local acts of parliament, and, much more, of *selling* them, has been declared illegal.

In Scotland, pews in the parish churches are assigned by the heritors (q. v.) to the parishioners, who have accordingly the preferable claim on them; in towns the practice is to let them annually. As is well known, pews in dissenting churches are rented as a means of revenue to sustain general charges. In some parts of the United States, pews in churches are a matter of annual competition, and bring large sums. Latterly, in England, there has been some discussion as to the injuriously exclusive character of the 'pew system,' and a disposition has been manifested to abolish pews altogether, and substitute movable seats available by all indiscriminately. Several pamphlets have appeared on the subject. In the Roman Catholic churches on the Continent pews are seldom to be seen.

PEW'TER, a common and very useful alloy of the metals, tin and lead. Two other kinds of pewter have a more compound character. Common, or *ley-pewter*, consists of 4 parts of tin and 1 part of lead; *plate-pewter* is made of 100 parts of tin, 8 parts of

antimony, 2 parts each of bismuth and copper; another kind, called *trifle*, is composed of 88 parts of tin and 17 parts of antimony. Although these are the standard formulas, each kind is often much varied to suit the purposes of the manufacturer; the chief alteration being the addition of a large proportion of lead to the last, and a large increase of the same metal in the other two.

PEZENAS, a manufacturing town of France, in the department of Hérault, on the left bank of the river of that name, 25 miles west-south-west of Montpellier. It stands in a district remarkable for its beauty, and so well cultivated as to have received the name of the Garden of Hérault. It is famous for its healthy climate and clear sky. The vicinity produces excellent wine, and woollen and linen goods are manufactured. The trade, however, is chiefly in liquors, and P. is known as one of the principal brandy-markets of Europe. Pop. (1876) 7570.

PFEFFERS an extraordinary and much-visited locality in the Canton of St. Gall, Switzerland, five miles south-east of Sargans. It has been famous since the middle of the 11th c. for its hot baths, situated 2180 feet above sea-level, and 520 feet above the village of Ragatz. The old baths of P. are built on a ledge of rock a few feet above the roaring torrent of the Tamina, and are hemmed in by walls of rock towering above them to the height of 400 feet, and so far burying the baths within the gorge, that even in the height of summer sunlight appears above them only from ten to four. Above the old baths the walls of the ravine of the Tamina contract until they meet, covering up the river, which is there seen from a cavernous gap. The hot-springs are reached from the baths by means of a railed platform. This platform, leading to the hot spring, is secured to the rocks, and the Tamina churns its way through the cleft 30 or 40 feet below. The waters of the hot spring are now conveyed to Ragatz (about two miles below P.) by wooden pipes, 12,500 feet long. The waters, as they issue from the spring, have a temperature of 100° Fahr. A pint of the water, which is used both for drinking and bathing, contains only about three grains of saline particles.

PFEIFFER, IDA (*née* REYER), a celebrated female traveler, was born at Vienna, October 15, 1797, and from her earliest years showed a resolute and fearless, but not unfeminine disposition. In 1820, she married an advocate, named Pfeiffer, from whom she was obliged to obtain a separation, after she had borne him two sons, Oscar and Alfred, whose education devolved on herself. When she had settled them in life, and was free to act as she pleased, she at once proceeded to gratify, at the age of 45, her long-cherished inclination for a life of travel and adventure. Her first expedition was to the Holy Land. She left Vienna in March 1842, and returned in December of the same year, having traversed, alone and without guide, European and Asiatic Turkey, Palestine, and Egypt. She published an account of her eastern rambles in the following year (*Reise einer Wienerin in das Heilige Land*), which, like all her other works, has gone through many editions, and been translated into French and English. In 1845, she visited Northern Europe—Sweden, Norway, Lapland, and Iceland—and recorded her impressions in her *Reise nach dem Skandinavien, Norden und der Insel Island* (2 vols. 1846). But these journeys, which would have satisfied most women, were but little excursions in the eyes of this insatiable nomade, and only served to whet her appetite for something vaster. She resolved on a voyage round the world; and on the 28th of June 1846, sailed from Hamburg in a Danish brig for Brazil. Her descriptions of the scenery of that country and of the inhabitants—both native Indians and Brazilians—are exceedingly interesting. She then sailed round Cape Horn to Chile, and thence, after some time, across the Pacific to Otaheite, China, and Calcutta; crossed the Indian peninsula to Bombay, whence she took ship for the Persian Gulf, landed at Bassora, traversed a great part of Western Asia, Southern Russia, and Greece, and re-entered Vienna, November 4, 1848.

Two years later, she published a narrative of her travels and adventures, entitled *Eine Frauenfahrt um die Welt* (Vienna, 1850, 3 vols.). As a small recognition of her services, and of the singular energy, fortitude, and perseverance of her character, the Austrian government granted Madame P. a sum of £100. She now determined to go round the world again, but by a different route. Proceeding to England, she in May 1851, took ship for Sarawak, rounding the Cape of Good Hope, penetrated alone to the heart of Borneo, visited Java and Sumatra, lived for a time with some cannibal tribes, and sailed from the Moluccas to California, thence to Peru, scaled the peaks of Chimborazo and Cotopaxi, made a run through the principal of the United States, and returned to London in 1854. The second voyage, signalized by several scientific observations, is described in *Meine Zweite Weltreise* (Vien. 1856). But the more she traveled, the fiercer became her hunger for movement. In September 1856, she set out on what was to be her last expedition—namely, to Madagascar. After enduring terrible hardships, she got away, and came home to Vienna—to die. Her death took place October 28, 1858.

PFO'ZRHEIM, an important manufacturing town of the Grand Duchy of Baden, on the northern border of the Black Forest, stands on the Enz, at its confluence with the Nagold and Wurm, 55 miles S.S.E. of Mannheim, and on a recently constructed branch of the Mannheim and Basel Railway. Its trade has been greatly advanced by its position at the intersection of several minor lines of railway. P. contains the remains of an ancient castle, formerly the residence of the Markgrafs of Baden-Durlach; several churches, one of which, the *Schlosskirche*, on a height contains a number of monuments, with marble statues of the princes of Baden; a convent for noble ladies; industrial and other schools; chemical and iron-works; machine-shops, tanneries, and cloth and other factories. The principal articles of manufacture are gold and silver wares and trinkets, the chief markets for which are Germany and America. An important trade is carried on in timber, which is cut in the neighboring forests, and is floated down to Holland by the Neckar and Rhine. Pop. (1871) 19,801; (1875) 23,537.

PHÆ'DRUS, a Latin poet, whose works consist of fables. He was probably a Thracian or Macedonian, carried to Rome as a slave in his childhood, and brought up at the court of Augustus, who emancipated him. Under Tiberius, he was exposed to great danger from the hostility of Sejanus, but lived to see that general's overthrow, and died at an advanced age, probably in the reign of Claudius. Five books of fables, after the manner of Æsop, and called *Fabulae Æsopicae*, have been usually ascribed to him. The faults of the style have led, however, to the suspicion, not merely of alterations at a later date, but of later, and even much later, composition. The dry 'morals' have been supposed to indicate the Middle Ages as the period to which the work should probably be referred; but its authenticity is generally admitted. The first edition was published at Troyes in 1596. The text has subsequently occupied the attention of some of the greatest scholars and critics, from the days of Burmann and Bentley to the present time. A sixth book, containing 32 fables, has recently been discovered and published, of the authenticity of which, however, there are greater doubts than of that of the other books. The best edition is that of J. C. Orelli (Zürich, 1831).

PHÆNO'GAMOUS PLANTS. See PHANEROGAMOUS PLANTS.

PHAËTHON (i. e., the shining), in the writings of Homer and Hesiod, a frequent title of Helios the sun-god, and subsequently employed as his name.—P., in Greek mythology, is also the name of a son of Helios, famous for his unfortunate attempt to drive his father's chariot. Scarcely had the presumptuous youth seized the reins, when the horses, perceiving his weakness, ran off, and approaching too near the Earth, almost set it on fire. Whereupon the Earth cried to Jupiter for help, and Jupiter struck down P. with a thunderbolt into the Eridanus or Po. His sisters, the Heliades, who had harnessed the horses of the Sun, were changed into poplars, and their tears into amber.

PHAGEDÆ'NA (Gr., from *phagein*, to eat or corrode), designates a variety of ulceration in which there is much infiltration, and at the same time rapid destruction of the affected part. The sore presents an irregular outline, and a yellowish surface; it gives off a profuse bloody or ichorish discharge, and is extremely painful. It usually attacks persons whose constitutions are vitiated by scrofula, by the syphilitic virus, by the abuse of mercury, by intemperance, &c. It not very infrequently appears in the throat after scarlatina in a severe form. If relief is not afforded by the internal administration of opium (to allay the pain), and of quinia, or some other preparation of bark, wine, beef-tea, &c. to improve the tone of the constitution, together with astringent and sedative local applications, recourse must be had to the destruction of the part by strong nitric acid, or some other caustic.

The terrible disease known in civil practice as SLOUGHING PHAGEDÆNA, and in military and naval practice as HOSPITAL GANGRENE, is merely, according to some of our highest surgical authorities, a state of phagedæna in its fullest development. This disorder requires for its development the influence of some of those undefined causes which regulate the outbreak of epidemics, and is peculiarly characterized by its contagious and infectious nature. It is usually engendered by the overcrowding of sick and wounded men, and some idea of its virulence may be formed from the fact that on the return of the French fleet from the Crimean war, no less than 60 deaths from it occurred in one ship in the course of 38 hours. It is not of frequent occurrence in the London Hospitals; but it broke out in the Middlesex Hospital in 1835, in University College Hospital in 1844, and in St. Bartholomew's and St. George's Hospitals in 1847 (Druitt's *Surgeon's Vade-mecum*, 8th ed., p. 72, note). For details respecting this disorder the reader is referred to Hennen's *Principles of Military Surgery*, Boggie On *Hospital Gangrene*, and the article on 'Gangrene,' by Mr. Holmes Cooté in Holmes's *System of Surgery*, vol. I.

PHALACRO'CORAX. See CORMORANT.

PHALÆ'NA. See MOTH.

PHA'LANGER or PHALANGIST (*Phalangista*), a genus of marsupial quadrupeds, having a rather short head, short ears, short woolly fur, a long prehensile tail, sometimes completely covered with hair, and sometimes only at the base, and scaly towards the extremity; the dentition somewhat various as to the number of premolars, the incisors always six in the upper jaw and two in the lower, the true molars eight in each jaw, the canines of the lower jaw very small, and close to the incisors. The fore-paws are strong, and capable of much use in grasping food and bringing it to the mouth. A number of species inhabit Australia and the islands to the north of it. They live chiefly in trees, and feed on insects, small animals of various kinds, eggs, and fruits. The SOOTY P. or TAPOA (*P. fuliginosa*) is pretty common in Van Diemen's Land, and is much sought after on account of its fur, which is of a uniform smoky-black color, or tinged with chestnut, warm and beautiful. The tail is very bushy. It is nocturnal in its habits.—The VULPINE P. (*P. vulpina*), also called the VULPINE OPOSSUM, is very plentiful and widely diffused in Australia. The length of the animal from the point of the muzzle to the root of the tail is about 26 inches;

Vulpine Phalanger (*P. vulpina*).

the tail is about 15 inches long, and is bushy; the color is grayish-yellow on the upper parts, and tawny-buff below. The fur is not so much valued as that of the last species, but is used for various purposes. The flesh, although it has a strong peculiar flavor, is a favorite food of the Australian aborigines.—Nearly allied to this genus, is the genus *Cuscus*, of which one species, whitish-gray, spotted with brown, is plentiful in the Molucca and Papuan Islands.—Allied to the phalangers also are the Flying Phalangers (q. v.).

PHALA'NGIDÆ, a family of Trachearian Arachnida, popularly called *Harvest-men*, some of the species appearing in great numbers in fields during the hay and corn harvests. They resemble spiders in their general form, although their organs of respiration are very different. Their legs are extremely long and slender. Most of the species are very agile.

PHALANSTE'RIANISM (from Gr. signifying phalanx and solid), the system of living in communities called phalansteries, as suggested by Fourier, the French socialist. See FOURIERISM.

PHA'LANX, the ancient Greek formation for heavy infantry, which won for itself a reputation of invincibility, may be described as a line of parallel columns, rendered by its depth and solidity capable of penetrating any line of troops. The oldest phalanx was the Lacedæmonian or Spartan, in which the soldiers stood eight deep, the Athenian phalanx had been the same, until, at the battle of Marathon (480 B. C.), Miltiades reduced the depth to four men in order to increase his front. When Epaminondas organized the Theban army against Sparta, he felt that the Spartan line of battle would be impregnable to troops organized in their own manner. He therefore increased the depth and lessened the front of his phalanx, which enabled him to burst through the Spartan line, inflicting the sanguinary defeat of Leuctra (371 B. C.). Philip of Macedon had learned the art of war under Epaminondas, and when he resolved to make his state a military power, he formed the celebrated Macedonian phalanx (359 B. C.), which enabled him to conquer Greece, and with which his son Alexander subdued the eastern world. The Macedonian phalanx, as the latest form that organization assumed, and as the shape in which the phalanx encountered the military skill of the west, is deserving of description.

The line was 16 deep: a grand phalanx comprising 16,384 *hoplites*, or heavy-armed soldiers, subdivided as follows: the grand-phalanx was composed of four phalanxes or divisions, each under a general officer, called a *phalangarch*; his command was divided

into two brigades or *merarchies* (sometimes called *tetarchies*), each of these comprising two regiments, or *chiliarchies*, of four battalions or *syntagma* each. A *syntagma* answered accurately to a modern battalion, except that it was smaller. It was a perfect square, with 16 men each way, was commanded by a *syntagmarch* or *zenagos*; and had an adjutant, with one or two other staff-officers who stood behind. Eight files united were under a *taxiarch*, four under a *tetarch*, corresponding probably to a modern captain, two files were under a *dilochite* or subaltern. A single file of 16 men was called a *lochos*, and the best man was placed at its head; a picked man, the *ouragos*, also marching in the rear. The arms of all these phalanx-men were pikes or spears, 24 feet long, of which 6 feet were behind and 18 feet held in front of the combatant. As each man occupied with his shield three feet, the phalanx, when it advanced, had six tiers of spear-point, a wall of steel which no troops could withstand, especially as the bearers of the spears were pressed on by the ten ranks in their rear. By rapid movements the phalanx could change front, form in close column of *syntagma*, and execute other critical manoeuvres.—The heavy-armed phalanx was ordinarily flanked by *peltastes* or light infantry, similarly formed, but only eight deep, while the cavalry were but four deep. The phalanx, as representative of the heavy formation, came in contact with the lighter legion of Rome during the wars of Pyrrhus in Italy.—At the great battle of Heraclea (279 B. C.), the phalanx won the day; but the victory was attributable to other causes as much as to any superiority of formation.

PHA'LARIS, a tyrant of Agrigentum in Sicily, who flourished about the middle of the 6th c. B. C. According to the prevalent tradition, he was infamous for his cruelty. He maintained his power for 16 years by the aid of foreign hirelings, and, it is said, by putting to death all persons of eminence in his dominions; but at last he fell a victim to popular indignation. He gratified, we are told, his love of cruelty by causing persons to be roasted alive in a brazen bull, which was made for that purpose—the first victim being the maker, Perillus. Cicero calls him the 'most cruel of all tyrants' (*crudelissimus omnium tyrannorum*). But some doubt attaches to this view of his character, partly because many of the crimes laid to his charge are intrinsically improbable, and partly because later traditions represent him as fond of literature and philosophy, and a patron of learned men. Lucian affirms that he was naturally a man of a mild and humane disposition. How far the later view should be allowed to modify the earlier, it is—in the absence of all reliable knowledge—impossible to say. It is under the later aspect that he is shown to us in the famous but spurious *Epistles of Phalaris*. See BENTLEY.

PHA'LAROE (*Phalaropus*), a genus of birds of the family *Lobipedidae* (q. v.); having a rather long, slender, weak, straight bill, resembling that of the sandpipers, which, indeed, they otherwise much resemble, although differing in their aquatic habits; the greater part of their time being passed in swimming on the sea, where they seek molluscs and other small marine animals for their food. The GRAY P. (*P. lobatus*), although formerly so rare a bird in Britain that Pennant says he only knew of two instances of its occurrence in his time, is now not unfrequently seen in its autumn migration from its northern abode to its southern winter-quarters. It breeds in the Arctic regions both of the old and new

Gray Phalarope (*P. lobatus*).

world, migrating southward in both on the approach of winter. Its entire length is rather more than eight inches. The tail is short. It is a beautiful bird, and remarkable for the great difference of its summer and winter plumage, the prevailing tint in winter being a delicate gray, whilst in summer the upper parts exhibit a fine mixture of black, white, and yellow, and the breast and under parts are reddish chestnut.—The RED-NECKED P. (*P. hyperboreus*, or *Lobipes hyperboreus*, a generic distinction being made by Cuvier and others, on account of the sharper and more

slender bill), breeds in some of the northern Scottish islands, although it is more common in more northern regions, and, like the former, is found in all the northern parts of the world. It is rather smaller than the Gray P., and is, like it, very graceful in form and movements, and finely colored. The phalaropes are very fearless of man, and very easily tamed. Their flesh is oily and unpalatable.

PHALLUS, a representation of the male generative organs, used at certain Dionysian festivals in ancient Greece, as a symbol of the powers of procreation. It was an object of common worship throughout the nature-religion of the East, and was called by manifold names, such as *Linga* (q. v.), *Joni*, *Pollear*, &c. Originally, it had no other meaning than the allegorical one of that mysterious union between the male and female, which throughout nature seems to be the sole condition of the continuation of the existence of animated beings, but at a later period, more particularly when ancient Rome had become the hot-bed of all natural and unnatural vices, its worship became an intolerable nuisance, and was put down by the senate on account of the more than usual immorality to which it gave rise. Its origin has given rise to much speculation, but no certainty has been arrived at by investigators. The Phœnicians traced its introduction into their worship to Adonis, the Egyptians to Osiris, the Phrygians to Attys, the Greeks to Dionysus. The common myth concerning it was the story of some god deprived of his powers of generation—an allusion to the sun, which in autumn loses its fructifying influence. The procession in which it was carried about was called *Phallagoga*, or *Periphallia*, and a certain hymn was sung on that occasion, called the *Phallikon Melos*. The bearers of the phallus, which generally consisted of red leather, and was attached to an enormous pole, were the *Phallophoroi*. Phalli were on those occasions worn as ornaments round the neck, or attached to the body. Aristotle traces the origin of comedy to the ribaldry and the improvised jokes customary on those festivals. Phalli were often attached to statues, and of a prodigious size; sometimes they were even movable. At a procession of Ptolemy Philadelphus, a phallus was carried about made of gold, and 120 yards long. Before the temple of Venus at Hierapolis there stood two phalli, 180 feet high, upon which a priest mounted annually, and remained there in prayer for seven days. The phallus was an attribute of Pan, Pirapus, and to a certain extent also of Hermes.

PHALLUS, a genus of fungi of the division *Gasteromycetes*, egg-shaped, the outer covering at length bursting to permit the growth of a stem, the receptacle which produces the spores, and which is surmounted by a rudimentary *pileus*. The most common British species, *P. impudicus* or *foetidus*, popularly called *Stinkhorn*, is as large as a hen's egg, growing underground in thickets, and finally sending up a stem 4–6 inches high, the fetid smell of which is felt for many yards around. The egg is full of a jelly-like substance. The growth of the stem is very rapid, and it soon decays.

PHANEROGAMOUS (Gr. *phaneros*, manifest; *game*, marriage) **PLANTS**, or **PHÆNOGAMOUS** (Gr. *phaino*, to show) **PLANTS**, are those plants which have true flowers, and in which the sexual organs (stamens and pistils) are distinctly notable. They are also called **FLOWERING PLANTS**, being by all these names contradistinguished to **Cryptogamous Plants** (q. v.). The seeds of *P. P.* originate from *Ovules* (q. v.), and already contain the young plant, more or less perfectly formed, which is called the *embryo*. *P. P.* are about three-fourths of all known plants. Among them are included all the larger plants, and all plants of great importance in an economic point of view. They are generally divided into *Monocotyledonous* or *Endogenous Plants*, and *Dicotyledonous* or *Exogenous Plants*.

PHARAOH. The name given by the Hebrews to the monarch ruling in Egypt at the time, in the same manner as Cæsar was applied to the Roman emperors, and as Khan is to the Tartar and Shah to the Persian rulers. The word is of uncertain etymology, being capable of two derivations—viz., either *Pa ra*, 'the Sun,' which is the leading or first title of all Egyptian monarchs, or the popular expression, *Pi ouro*, or *Phouro*, 'the King.' It is even possible to derive it from *Pa har*, 'the Horus,' another title of Egyptian monarchs. The greatest difficulties have been encountered in attempting to determine the particular monarchs who pass under this name in the Scriptures. The first-mentioned *P.* is the one in whose reign Abraham visited Egypt, who is supposed by some chronologists to have been one of the Shepherd Monarchs, but nothing can be offered beyond mere conjecture in support of this theory. Another *P.* is the one in whose reign Joseph was brought to Egypt, and who was supposed by Eusebius to be Apophis, one of the later Shepherd Kings of the seventeenth dynasty, who are known from the monuments to have immediately preceded the eighteenth. Bunsen indeed places the arrival of Joseph in the reign of Usertesen, or, as he reads his name, Sesertesen I. of the 12th dynasty, in which indeed a famine

is stated in the hieroglyphical texts to have happened, and in which it appears numerous officers were established to take charge of the grain. Arguments, however, may be adduced for Joseph having arrived in the time of the 12th dynasty, from the fact of the establishment of the family of Jacob in the land of Goshen, the importance to which Joseph had risen, and the omission of the name of any of the principal Egyptian cities in the narrative, and the fact of Joseph having married Asenath, the daughter of Potipherah, priest of Heliopolis, a city evidently the seat of the court under the 12th dynasty, as Onar or Ovaris was under the Shepherds.

Equal difficulty is experienced in determining the *P.* who reduced the Israelites to bondage, employed them in the labors of the brick-field, and compelled them to build the treasure-cities of Pithom and Rameses. He appears to have meditated the total absorption of the Hebrews into the Egyptian race. All that is clear from the narrative is that the city of Rameses was called after his name, in the same manner as modern forts have been by contemporary rulers. Now frequent mention occurs in the Papyri and other texts of the *Makatalu en Ramesseu*, or Tower of Rameses II., which is represented on the walls of Medinet-Abu; and this has induced Lepsius and Bunsen to depress the date of the Exodus from 1491 B.C. to the close of the nineteenth dynasty, or after Rameses II., a point controverted by other chronologists, who wish to elevate it to the middle of the 18th dynasty, or 1732 B.C. To synchronize the former date, Lepsius takes the rabbinical date of 1314 B.C. for the Exodus, or 1340 B.C. for the birth of Moses. The *P.* of the Exodus is supposed to be the Meriפתח or Menephthes, the son and successor of Rameses II. Philologically, this explanation is preferable, as the fixed point in the inquiry is the name of the Migdol of Rameses found both in the Scriptures and on the monuments of Egypt. Other Pharaohs are mentioned; as the father of Tahpenes, wife of Hadad and mother of Genuboth; the *P.* whose daughter Solomon married; *P.* Nechao, or Necho II., who gave battle to Josiah, king of Judah, whom he slew at Megiddo, and who made war against the Syrians, defeated them at Magdolu, and took Cadytus or *Katsh*, on the *Ararat* or Orontes. He was subsequently defeated by Nebuchadnezzar at Carchemish, 607 B.C. *P.* Hophra, was the Uaphris or Apries of the Greeks, whose destruction was prophesied by Jeremiah, and who was strangled 570 B.C.—Bunsen, *Ägyptens Stelle*, iii. p. 109; Lepsius, *Einleit.* p. 317; Nash, *The Pharaoh of the Exodus* (8vo, Lond. 1862).

PHARISEES (*Perishin* or *Perushim*, Separatists), a so-called 'Jewish sect,' more correctly, however, a certain Jewish school, which probably dates as a distinct body or party from the time of the Syrian troubles, and whose chief tendency it was to resist all foreign, chiefly Greek, influences that threatened to undermine the sacred religion of their fathers. They most emphatically took their stand upon the Law, together with those inferences drawn from its written letter which had, partly from time immemorial, been current as a sacred tradition among the people. Out of the small band of the Chasidim (q. v.), the *P.* had taken their rise originally as *Chaberim*, Friends, Colleagues, Scholars—in contradistinction to the *Am-Haarez*, or common-people—and their chief object in life was the Divine Law, its study and further development. Principally distinguished by their most scrupulous observance of certain ordinances relating to things clean and unclean, they further adopted among themselves various degrees of purity, the highest of which, however, was scarcely ever reached by any member of their community. For every degree, a special course of instruction, a solemn initiation, and a novitiate was necessary; all of which, together with a certain distinction in dress, seems to have been imitated from them by the Essenes (q. v.). The name of *P.* or *Perushim* was probably at first bestowed upon them in derision by the Sadducees or Zadokites, the priestly aristocracy and their party, the Patricians, who differed from them politically, and to some extent also in religious matters. The *P.* had no special 'Confession of Faith,' or articles of creed different from the whole body of Jews.

The Bible, as interpreted by the traditional Law, was their only code. Obedience to this Law, strictest observance of all religious and moral duties, submission to the Divine will, full confidence in the wisdom and justice of Providence, firm belief in future reward and punishment, elasticity, meekness, and forbearance—these were the doctrines inculcated in their schools. They were, in fact, nothing more or less than the educated part of the people, who saw in the rigid adherence to the ancient religion, such as it had developed itself in the course of centuries, the only means of saving and preserving the commonwealth, notwithstanding all its internal and external troubles. Hence, they wished the public affairs, the state and all its political doings, to be directed and measured by the standard of this same Divine Law; without any regard for those aristocratic families who ruled, or at all events greatly influenced the commonwealth. These consisted of the priestly families, the Zadokites (Sadducees, q. v.), and of the val-

fant heroes and sagacious statesmen, who had brought the Syrian wars to a successful issue, and had, by prudent negotiations with other courts, restored the nation to its former greatness, and, on their own part, had acquired wealth and fame, and freer and wider views of life and religion. The latter held the modern doctrine, that religion and state were two totally different things; that God had given man the power of taking his matters into his own hands; and that it was foolish to wait for a supernatural interference, where energy and will were all that was required.

Naturally enough, the political difference between the two parties by degrees grew into a religious one, since the Jewish State was one still completely pervaded by the religious element—as indeed it had begun as a theocracy, and could still, to a certain extent, be called by that name. And the more the Sadducees lost their influence—the people siding with the P.—the more the religious gulf must have widened between them; although the divergence between them, as far as our authorities—Josephus, the New Testament, and the Talmud—go, does not seem to have been of a very grave nature. Thus, the P. assumed the dogma of immortality, chiefly with a view to a future reward of good and evil deeds in this world; while the Sadducees, without rejecting—as we are erroneously informed by Josephus—this dogma in the least, yet held that there was nothing in the Scripture to warrant it, and, above all, that there was no need of any future reward; at any rate, that a pious life with a view to this was not meritorious. While the P. held all the traditional ordinances in equal reverence with the Mosaic ones, tracing, in fact, most of the former to Sinai itself, the Sadducees rejected, or rather varied some of these according to the traditions of their own families; these ordinances chiefly relating to priestly and sacrificial observances, certain laws of purity, and some parts of the civil law. It may perhaps even be assumed, with the most recent investigators (chiefly Geiger), that the P. were the representatives of a newer Halacha, dictated by an oppositional and religious and national zeal which carried them far beyond the original boundaries.

Certain other legal differences between the two parties, such as the application of the laws of inheritance to daughters, or of the responsibility of the master for his servants, are nothing more than political party-views in a religious mask, which were meant to meet certain specially isolated cases only. In general, the P. handled justice in a much milder manner than their antagonists, who took their stand upon the rigid letter, and would hear of no mercy where a violation of the code was clearly made out. Out of the midst of the P. rose the great doctors and masters of the Law (*Soferim*, Scribes, *Nomodidaskaloi*, teachers of the Law), and to them were intrusted by the later rulers the most important offices.

Until recently the greatest misconception has prevailed even among scholars respecting this self-sacrificing, patriotic, pious, learned, and national party of progress. That there were among them those who were a disgrace to any party, and still more, to their strict one, no one knew better than the P. themselves, and in bitter words than were ever used by Christ and the apostles, the Talmud castigates certain hyperpious members of their own community as the 'plague of Pharisaism.' These hypocrites were characteristically styled *Zebuiim* [dyed, painted ones], 'who do evil deeds like Zimri, and require a godly reward like Phinehas.' Seven kinds of P. are enumerated in the Talmud, six of whom were not to be counted as real Pharisees—viz. (1) they who did the will of God for earthly motives; (2) those who made very small steps, or said: Wait for me—I have still some good deed to do; (3) those who knocked their heads against walls, lest they might look at a woman; (4) *ex-officio* Saints; (5) those who say: tell me of another duty; (6) those who are pious, because they fear God. The only genuine Pharisee was he 'who did the will of his Father in Heaven, because he loved Him.'

Josephus's accounts, distortions in themselves, have, to add to the confusion, been misunderstood (thus, for example, the word which he uses to designate the three parties, never meant 'sect,' as it has invariably been interpreted); and the position of Christ, in relation to the P., can never be understood properly without a full acquaintance with the circumstances of the time, to which there is no other way than a knowledge of that literature (the Talmud and Midrash) which has so long been neglected. Christ found the influence of the P. predominant among the people, although the Sadducees (and the Boethusians) were in reality the ruling classes and allies of the reigning dynasty. He naturally sided with the democratic party of the P. against that of the proud opposite camp. As for the religious tendencies of the latter, the Sadducees (q. v.)—the people had decided that point already practically, by siding with the Pharisees. Once only an allusion is made also to the leaven of Herod—the Sadducees (Mark viii. 15, cf. Matt. xvi. 6). But it was, above all things, necessary to combat the ever-growing tendency to choke up, as it were, all real piety and genuine virtue of heart under external ceremonies and observances, which, unless guarded against, will appear, instead of a mere symbol and memento, the essence of religion itself, and thus become in time

a delusion and bondage, and end in that vile hypocrisy, against which the Talmud fights with all its powers of derision, and Christ inveighs in much more vehement terms than is his wont. It was not in themselves that these 'oral laws' were held up to scorn. They were a necessary and natural growth, and acted, in the main, beneficially; as is now fully recognized by scholars of eminence. (For some further remarks on the subject, see TALMUD.)

Pharisaism—from which gradually branched off the wild democratical party of *Zealots* (Kannaim), and which for the last time represented political opinions in the revolution of Bar Cochba—has, from the downfall of the sanctuary, and the final destruction of the commonwealth of this day, remained the principal representative of Judaism as a creed only, Sadduceism dying out, or, at all events, producing only one such sterile plant as Karaism. See JEWISH SECTS, SADDUCEES.

PHARMACOPEIA. This term has been applied to various works, consisting for the most part of (1) a list of the articles of the *Materia Medica*, whether simple or compound, with their characters, and the tests for the determination of their purity; and (2) a collection of approved receipts or prescriptions, together with the processes for articles in the *Materia Medica*, obtained by chemical operations. Almost every civilized country of importance has its national pharmacopœia, amongst which those of the United States, France, and Prussia deserve specially honorable notice. The first pharmacopœia published under authority appears to have been that of Nuremberg in the year 1542. A student named Valerius Cordus, who was staying for a short time at Nuremberg, showed a collection of medical receipts, which he had selected from the works of the most eminent writers, to the physicians of that city, who were so struck with its value that they urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the senatus. Before this time, the books chiefly in use amongst apothecaries were the treatises: *On Simples* by Avicenna and Serapion; the *Liber Serapionis* of Balchasis ben Aberazerim; the *Antidotarium* of Johannes Damascenus or Mezue, arranged in classes; and the *Antidotarium* of Nicolaus de Salerno, which was arranged alphabetically. This work was commonly called *Nicolaus Magnus*, to distinguish it from an abridgment known as *Nicolaus Parvus*.

Confining our remarks to the British Pharmacopœias, we may notice that the first edition of the London Pharmacopœia (or, more correctly speaking, of the Pharmacopœia of the London College of Physicians) appeared in 1618, and was chiefly founded on the works of Mezue and Nicolaus de Salerno. Successive editions appeared in 1627, 1635, 1650, 1697, 1721, 1746, 1787, 1809, 1824, 1836, and 1851; and form an important contribution to the history of the progress of pharmacy and therapeutics during the last two centuries and a half. The nature and the number of the ingredients that entered into the composition of many of the pharmaceutical preparations of the 17th and 18th centuries, would equally astonish most of the practitioners and patients of the present day. In the earlier editions we find enumerated earth-worms, snails, wood-lice, frogs, toads, puppy dogs, foxes ('a fat fox of middle age, if you can get such a one'), the skull of a man who had been hanged, the blood of the cat, the urine and excrements of various animals, &c.; and eleutheraries were ordered, containing 50, 62, and in one instance—Mathiolus, his Great Antidote against Poison and Pestilence—124 different ingredients.

The Edinburgh Pharmacopœia is more modern than the London, the first edition having appeared in 1699; while the Dublin Pharmacopœia does not date further back than 1807. The latest edition of these works appeared in the years 1841 and 1850 respectively.

Until the Medical Act passed in 1858, the right of publishing the pharmacopœias for England, Scotland, and Ireland was vested in the Colleges of Physicians of London, Edinburgh, and Dublin respectively; and as these three pharmacopœias contained many important preparations, similar in name but totally different in strength (as, for example, dilute hydrocyanic acid, solution of hydrochlorate of morphia, &c.), dangerous complications arose from a London prescription being made up in Edinburgh or Dublin, or *vice versa*. By that act it is ordained that 'the General [Medical] Council shall cause to be published, under their direction, a book containing a list of medicines and compounds, and the manner of preparing them, together with the true weights and measures by which they are to be prepared and mixed; and containing such other matter and things relating thereto as the General Council shall think fit, to be called *British Pharmacopœia*, which shall for all purposes be deemed to be substituted throughout Great Britain and Ireland, for the several above-mentioned pharmacopœias.' The *British Pharmacopœia*, published in 1864, had the merit of amalgamating the London, Edinburgh, and Dublin Pharmacopœias; but it unfortunately contained so many defects, that, in accordance with the universal wishes both of the medical profession and of the chemists, the Medical Council or-

dered a new edition to be as speedily as possible prepared. This new edition has met with general favor from the profession; and it is to be hoped that as we have now succeeded in incorporating three distinct works into one, we may hope by and by to have a universal Pharmacopœia, or, at all events, one of so general a nature that the most important medicines of the American, British, and chief continental Pharmacopœias shall all be of the same strength.

PHARMACY (from the Gr. *pharmakon*, a medicine) is that department of *Materia Medica* (q. v.) which treats of the collection, preparation, preservation, and dispensing of medicines. It is synonymous with *Pharmaceutical Chemistry*.

PHAROS, a rocky islet off the coast of Egypt, which Alexander the Great connected with Alexandria by the Heptastadium, or Seven Furlong Mole. The light-house at its N.E. point, commenced by Ptolemy I. and finished about 280 B.C., was looked upon as one of the wonders of the world. It seems to have been 400 feet high, and lasted 1600 years. The fire, constantly kept lighted on its summit, was said to be visible for 40 miles. The island of P. became ultimately a suburb of Alexandria by means of a street extending along the mole. After the time of Julius Cæsar, it relapsed into the condition of a mere fishing station.

PHARSA'LUS, now **FERSALA**, a town of Thessaly, to the south of Larissa, on a branch of the Salambria, and accordingly in the part of Thessaly restored to Greece in 1881. It is historically notable mainly for the great battle fought here between Cæsar and Pompey, August 9, 48 B.C. Pompey had about 45,000 legionaries, 7000 cavalry, and a great number of light-armed auxiliaries. Cæsar had 22,000 legionaries and 1000 German and Gallic cavalry. The battle, which commenced with an attack on Pompey's left wing, ended in a complete victory for Cæsar, and determined the fate of the Roman world.

PHARYNGOBRA'NCHI, a sub-order of Dermopterous (q. v.) fishes, characterized by respiratory processes projecting from above the pharynx into the large cavity of the mouth. The P. have no heart, and are the lowest in organization of all fishes. The species are very few. See **LANCELET**.

PHARYNGOGNA'THI, an order of fishes, in the system of Müller and Owen; partly *Acanthopterous* and partly *Malacopterous* in the system of Cuvier; some of them also *Cycloid*, and some *Otenoid*. Their common characteristic is the union of the lower pharyngeals into one bone.

PHARYNX (Gr.) is the name of that part of the alimentary canal which lies behind the nose, mouth and larynx. It is a musculo-membranous sac, situated upon the cervical portion of the vertebral column, and extending from the base of the skull to the level of the fifth cervical vertebra, where it becomes continuous with the *Œsophagus* (q. v.). Its length is about four inches and a half, it is broader in its transverse than in its antero-posterior diameter, and its narrowest point is at its termination in the *Œsophagus*. Seven *foramina* or openings communicate with it—

Fig. 1.—The Pharynx laid open from behind:

1, a section of the base of the skull; 2, 2, the walls of the pharynx drawn to either side; 3, 3, the posterior nares, separated by the vomer; 4, 4, the extremities of the Eustachian tubes; 5, the soft palate; 6, 6, 7, 7, its posterior and anterior pillars; 8, the root of the tongue; 9, the epiglottis overhanging; 10, the opening of the larynx; 11, the posterior part of the larynx; 12, the opening into the *Œsophagus*, whose external surface is seen at 13; 14, the trachea. (From Wilson.)

viz., the two *posterior nares* or nostrils, at the upper and front part of the P.; the two *Eustachian tubes*, opening on the outer surface of the preceding orifices; the *mouth*; the *larynx*; and the *Œsophagus*.

The P. is composed of an external *muscular* coat; a middle

fibrous coat called the *pharyngeal aponeurosis*, thick above where the muscular coat is absent, and gradually thinning as it descends; and a *mucous* coat, continuous with the mucous mem-

Fig. 2.—External View of the Muscles of Pharynx:

1.—the orbicularis oris muscle; 2, the Buccinator muscle; 3, portion of lower jaw, part of which is cut away; 4, pterygo maxillary ligament; 5, the hyoid bone; 6, the thyroid cartilage; 7, the bicoid cartilage; 8, the trachea; 9, the *Œsophagus*, with the recurrent laryngeal nerve lying between it and the trachea; 10, the stylo-pharyngeus muscle; 11, 12, 13, the superior, middle, and inferior constrictor muscles.

brane of the mouth and nostrils. The muscular coat requires special notice. It is composed of a *superior*, *middle*, and *inferior constrictor* muscle on either side, together with two less important muscles, termed the *stylo-pharyngeal* and *palato-pharyngeal* muscles. When the food, after being sufficiently masticated and mixed with saliva, is thrown, by the action of the tongue, into the P., the latter is drawn upwards and dilated in different directions; the elevator muscles (the stylo-pharyngeal and palato-pharyngeal) then relax, and the P. descends; and as soon as the morsel is fairly within the sphere of action of the constrictor muscles, they successively contract upon it, and gradually pass it onwards to the *Œsophagus*. Independently of its importance in the act of swallowing, the P. exerts an influence on the modulation of the voice, especially in the production of the higher notes.

The P. is not so frequent a seat of disease as many other parts of the intestinal tube. In cases of *Diphtheria* (q. v.) it is usually the chief seat of the disease. It is liable to ordinary inflammation or *pharyngitis*—an affection characterized by pain, especially in swallowing, without redness in the fauces or change of voice. Little in the way of treatment, except low diet and attention to the bowels, is required; and the inflammation usually terminates in resolution. Sometimes, however, it proceeds to suppuration, and abscesses—dangerous partly from inanition consequent on inability to take food, but chiefly from suffocation due to pressure on the larynx are formed. These abscesses are more dangerous in the lower than in the upper part of the P., and are more common in young children than in adults. The treatment consists in opening the abscess, which gives immediate relief; but the operation must be conducted with great care, and the incision made as nearly as possible to the mesial line, in consequence of the large adjacent blood-vessels.

PHASCO'GALÉ, a genus of marsupial quadrupeds, of which one species, *P. penicillata*, about the size of a rat, gray, with long soft hair, and a long tufted tail, is common in most parts of Australia, lives chiefly in the hollows of decayed trees, and preys on small animals of every kind. It is much disliked by the colonists, to whom it is known as the *Tapoa Tafa*, on account of its depredations in poultry-yards and larders. It is very agile and audacious.

PHASE'OLUS. See **KIDNEY-BEAN**.

PHASES (Gr. *phasis*, appearance), the different luminous appearances presented by the moon and several of the planets, sometimes the whole, a part, or none, of the luminous surface being seen from the earth. The various phases of the moon, and the reasons of them, are mentioned under the article **MOON**. Mercury and Venus, being inferior planets, present to an observer on the earth exactly similar phases to those of the moon; but the former require, instead of a month, periods of 116 and 584 days respectively to pass through a complete series of phases. The superior planets, to a certain extent, exhibit phases, but the luminous surface, as seen from the earth, only varies from the full illumination seen when they are in conjunction with the earth to a slightly gibbous

appearance when they attain their greatest elongation; and their distance from the sun is so great in comparison with that of the earth, as to render the variation in the form of their luminous surface not observable, except in the case of Mars and occasionally of Jupiter. Galileo was the first to observe the phases of Venus, and he considered them as one of the most satisfactory proofs of the truth of the Copernican system. The great brilliancy of Mercury, and its nearness to the sun, prevented its phases from being so easily noticed, but they were at last observed by Masius, and since by many other astronomers. The term phases is frequently applied to designate the successive stages of an eclipse, lunar or solar.

PHASIA'NIDÆ, a family of gallinaceous birds, including pheasants, argus, Macartney cock, fowls, impeyans, tragopans, &c.; its limits, however, being extended by some ornithologists to include peacocks and turkeys (*pavonida*), which differ from it by no very considerable character. The hind-toe is placed higher on the tarsus than the front toes, so that only the tip touches the ground. The wings are short.

PHA'SIS, a river in Colchis, now called the **RION**. It rises in the mountains of Caucasus, flows in a generally western direction, and enters the Euxine near the ancient city of Phasis.

PHA'SMIDÆ (Gr. *phasma*, a spectre), a family of orthopterous insects, allied to *Mantidæ*, but differing in having the fore-legs similar to the other legs, and used like them for locomotion, not for combat and prehension, in the want of stigmatic eyes, and in the similarity of the first joint of the thorax to the other joints. They are insects of very extraordinary appearance, inhabiting tropical countries, and spending their lives upon trees and shrubs, the tender shoots of which they devour. Some of them resemble green leaves; some resemble brown and withered leaves; whilst others, wingless, or nearly so, and with much elongated bodies—one species nine inches in length—resemble dry twigs. To these peculiarities they owe their safety from enemies, eluding observation, for their motions are sluggish. Some are known as Leaf Insects, Spectre Insects, Walking-sticks, &c. The larvæ of the *P.* much resemble the perfect insect.

PHEA'SANT (*Phasianus*), a genus of gallinaceous birds of the family *Phasianidæ*; having a rather short strong bill, a little curved; the cheeks and skin surrounding the eyes destitute of feathers, and warty; the wings short; the tail long, its feathers so placed as to slope down, roof-like, on either side, the middle feathers longest; the tarsus of the male furnished with a spur. The males of all the species are birds of splendid plumage; the females have shorter tails and dull or somber colors. There are numerous species, natives of the warm and temperate parts of Asia. The **COMMON P.** (*P. Colchicus*) is said to have been brought from the banks of the Phasis, in Colchis, to the south of Europe, at a very remote period, its introduction being ascribed in classic legend to the Argonauts. From the Phasis it derived its Greek name *Phasianos*, the origin of its name in English and other modern languages. It was soon naturalized in Europe, and is now diffused over almost all the temperate parts of it. The date of its introduction into Britain is not known, but was certainly before the end of the 13th c.: it has long been plentiful in plantations and game-preserves, and has been introduced into almost every part of the country suitable to its habits. The abundance of pheasants in Britain, however, is to be ascribed chiefly to careful game-preservation, without which the race would in all probability soon be extirpated. No kind of game falls so easy a prey to the poacher.

A minute description of the Common *P.* is unnecessary. The head and neck of the male are steel-blue, reflecting brown, green, and purple in different lights; the back and wings exhibit a fine mixture of orange-red, black, brown, and light yellow; the breast and belly are golden-red, each feather margined with black, and reflecting tints of gold and purple. The whole length of a male *P.* is about three feet, of which the tail often measures two feet. The entire length of the female is about two feet. The general color of the female is pale yellowish-brown, varied with darker brown, the sides of the neck tinged with red and green. The ordinary weight of a *P.* is about two pounds and a half; but when pheasants are abundantly supplied with food, and kept undisturbed, they are sometimes four pounds or four pounds and a half in weight. The *P.*, unlike the partridge, is polygamous.

The nest of the *P.* is on the ground, and is a rude heap of leaves and grasses, in which eleven or twelve olive-brown eggs are laid. But in the half-domesticated state in which it exists in many English preserves, the *P.* does not pay that attention to its eggs and young which it does when more wild, and not unfrequently continues to lay eggs for a considerable time, like the domestic fowl; the eggs being removed by the gamekeeper, and hatched by hens, along with eggs from nests found among clover and hay in the season of mowing. Very young pheasants must be carefully supplied with ants' eggs, maggots, &c., and the whole difficulty of rearing them is in their earliest stage.

Pheasants feed very indiscriminately on berries, seeds, roots, young shoots of plants, worms, insects, &c. Beans, pease, corn, and buckwheat are frequently thrown for them in open places in woods; and they scrape up bulbous and tuberous roots in winter. They roost in trees at no great height from the ground, and poachers sometimes capture them by burning sulphur below them. During the moulting season, they do not ascend trees to roost, but spend the night on the ground, when they fall a ready prey to foxes. They are fond of woods with a thick undergrowth, in which, when disturbed, they naturally seek shelter, running whilst it is possible, rather than taking flight. The male *P.* takes flight much more readily than the female, which, apparently trusting to her brown color to escape observation, often remains still until the sportsman is almost upon her. The males and females do not associate together except during the breeding season, but small numbers of one sex are often found in company. The 'short crow' of the males begins to be heard in March. In England and Scotland pheasant-shooting legally begins on the 1st of October, and ends on the 3d of February. The pheasants turned out from the gamekeeper's breeding-yard into a preserve, are in general supplied with abundance of food during winter, and come to the accustomed call as readily as any kind of poultry, so that the sportsmanship of a *battue*, in which they are killed by scores or hundreds, is of the lowest kind. It is scarcely necessary to mention that the flesh of the *P.* is in very high esteem for the table.

The female *P.*, in old age, or when from any cause incapable of the functions of reproduction, sometimes assumes the plumage of the male. The *P.* exhibits a remarkable readiness to hybridize with other gallinaceous birds. A hybrid between it and the common fowl is not unfrequent, and is called a *Pero*. Hybrids between the *P.* and Black Grouse have also occurred; and hybrids are supposed to have been produced between the *P.* and Guinea-fowl, and the *P.* and turkey. None of these hybrids, however, have ever been known to be fertile, except with one of the original species. On the contrary, the offspring of the Common *P.* and the **RING-NECKED P.** (*P. torquatus*) is perfectly fertile, a circumstance which is urged in argument by those who regard them as mere varieties of one species. The Ring-necked *P.* is now almost as plentiful in Britain as the Common *P.*: it is a native of the forests of India and China, and is said not to breed with the Common *P.* in a truly wild state, but in Britain they readily intermix. It is distinguished by a white ring almost surrounding the neck, and is of smaller size than the Common *P.*, somewhat different in markings, and has a shorter tail.—The **BOHEMIAN P.** is another variety of a silvery-gray color.—White pheasants are of not very unfrequent occurrence.—Of other species of *P.* may be mentioned **DIARD'S P.** (*P. versicolor*), a native of Java, in which the prevailing color is green; and **REEVES'S P.** (*P. Reevesii*), a native of the north of China, in which white is the prevailing color, and the tail is of extraordinary length, so that a bird not larger than the Common *P.* measures eight feet in entire length.

Of somewhat different type, and more nearly approaching to the common fowl, are the **GOLDEN P.** (*P. pictus*, or *Thaumalia picta*) and the **SILVER P.** (*P.* or *Gallophasid nycthemerus*), both natives of China, and both hardy birds, the introduction of which into British preserves has been attempted with good prospect of success. Both have long been kept in a state of domestication by the Chinese. The Golden *P.* is one of the most splendid of the tribe. It has a fine crest, and a ruff of orange and black, capable of being erected at pleasure. The tail is very long. The crest and ruff are held in great estimation by anglers for making artificial flies.—**LADY AMHERST'S P.** (*P.* or *Thaumalia Amherstiae*) is a native of China, resembling the Golden *P.*, and with an extremely long tail.—The Silver *P.* is one of the largest and most powerful of the tribe, and very combative, driving the Common *P.* from preserves into which it is introduced. The prevailing color of the upper parts and tail of the male is white, finely pencilled with black, the breast and belly purplish-black.—The name *P.* is sometimes extended to gallinaceous birds of allied genera.

PHEASANT-SHELL (*Phasianella*), a genus of gasteropodous molluscs of the family *Turbinidæ*, of which the shells are much valued for their beauty, and when they were rare in collections, were sometimes sold for extraordinary prices. They are now comparatively cheap and plentiful, being found in great numbers on some parts of the Australian coast.

PHEI'DIAS (Lat. *Phidias*), son of Charmides, the greatest sculptor of ancient Greece, born at Athens probably between 500—490 B.C. His first instructor in art was Hegias of Athens; he afterwards studied under a more famous master, Ageladas of Argos. He appears to have first acquired distinction in his profession soon after the battle of Salamis, and indeed his great works were all executed during a period most favorable for the development and encouragement of genius, when Greece was triumphant over external enemies, and her people enjoyed a more perfect liberty than

almost at any other period of their history. With the character of the age correspond the works of its poets, particularly of the tragedians Æschylus, Sophocles, and Euripides, and of its sculptors, particularly of Phidias. Under Cimon's administration the Athenians began the work of restoring their city, which the Persians had destroyed, in more than its former magnificence, and to fill it with noble works of art. P. was accordingly employed in making the colossal brazen statue of Minerva, *Athena Promachos*, which was placed upon the citadel, and was executed probably about 460 B.C. To the government of Cimon succeeded that of Pericles, still more brilliant, and signalized by an extraordinary development of art. Pericles not only gave to P. a commission to execute all the more splendid statues that were to be erected, but made him general superintendent of all works of art going on in the city. Plutarch tells us that P. had under him architects, statuary, workers in copper and bronze, stone-cutters, gold and ivory beaters, &c.

To P., as director-general of all the skilled artists and artificers of Athens, we owe, among other glorious edifices, the Propylæa and the Parthenon, the sculptured ornaments of which were executed under his direct superintendence, while the statue of the goddess Athene, the materials for which were ivory and gold, was the work of P. himself (circa 438 B. C.). This statue was clothed with a golden robe, which alone was worth 44 talents of gold. The statue is gone forever, and the Parthenon is now only a magnificent wreck, but we still possess some splendid evidence of the genius of P., in the sculptures of the metopes, and friezes of the temple of Athene. See ELGIN MARBLES. Next year P. went to Elis, where he executed a colossal statue of Zeus for the Olympium at Olympia (q. v.), also of ivory and gold (about 433 B. C.). This was reckoned his masterpiece. On his return to Athens, political passions were running high. There was a strong—at least a violent—party inimical to Pericles, but as they did not dare to attack the great statesman, they assailed him through his friends P., Anaxagoras, Aspasia, &c. P. was accused of having appropriated to himself some portion of the gold destined for the robe of Athene. This accusation he repelled by taking off the robe and weighing it. He was then accused of impiety, for having introduced his own likeness and that of Pericles on the shield of the goddess. On this most frivolous and contemptible pretext he was thrown into prison, and died there, but whether of sickness or poison is uncertain. His death took place about 432 B. C. The works executed by, or ascribed to P., were numerous, but we have mentioned the most celebrated. Their prevailing characteristic appears to have been an ideal sublimity, and even the imperfect relics that we possess are the most noble specimens of sculpture in the world.

PHENO'MENON (Gr. appearance), the name given in philosophy to an object or fact as it is perceived by us, as distinguished from what it is in itself. In the philosophy of Kant, that, whatever it may be, which is behind the phenomenon, and causes it, is called the *noumenon*, as being merely assumed or thought of in the mind. See METAPHYSICS, PERCEPTION.

PHÉ'NYL, and THE PHÉ'NYLIC GROUP. Phenyl (C_6H_5) is an organic radical, which has not yet been isolated. Its most important compounds are: (1.) Carbolic or Phenic Acid (HO, C_6H_5O), known also as Phenol, Hydrated Oxide of Phenyl, and Phenyl-Alcohol. See CARBOLIC ACID. (2.) Hydride of Phenyl (C_6H_5), known also as Benzole, Benzine, and Phene. See BENZOLE. (3.) Phenylamine or Phenylia (C_6H_5, H_2N , or C_6H_5, N), better known under the name of Aniline, one of the most important of the artificially formed bases.

Aniline derives its name from *anil*, an obsolete name for indigo, which is one of the sources from which it is most readily procured. It exists amongst the products of the distillation of coal, and probably other organic compounds, but is always obtained by the manufacturing chemist either from indigo or from nitro-benzole. Dr. Hofmann, to whom we are mainly indebted for our knowledge of the chemistry of this substance, gives the following directions for obtaining it from indigo: 'Powdered indigo boiled with a highly-concentrated solution of hydrate of potassa, dissolves with evolution of hydrogen gas to a brownish-red liquid, containing a peculiar acid, called the *anthranilic* acid. If this matter be transferred to a retort, and still further heated, it swells up, and disengages aniline, which condenses in the form of oily drops in the neck of the retort and in the receiver. Separated from the ammoniacal water by which it is accompanied, and re-distilled, it is obtained nearly colorless. The formation of aniline from indigo is represented by the following equation:

By this process, the indigo is made to yield about one-fifth of its weight of pure aniline. Nitro-benzole is converted into aniline by the action of various reducing agents, such as hydrosulphate of ammonia, or acetate of protoxide of iron; and the distillation of one part of nitro-benzole, one part of acetic acid, and one and a half parts of iron filings, is regarded by Hofmann as the best means of preparing aniline, which is now required in large quantities for the dyers.

'When pure,' says Dr. Hofmann, 'aniline forms a thin, oily, colorless liquid, of faint vinous odor, and aromatic burning taste. It is very volatile, but has nevertheless a high boiling-point, 359°-6. In the air, it gradually becomes yellow or brown, and acquires a resinous consistency. Its density is 1.028. It is destitute of alkaline re-action on test-paper, but is remarkable for the number and beauty of the crystallizable compounds it forms with acids. Two extraordinary re-actions characterize this body, and distinguish it from all others—viz., that with chromic acid, and that with solution of hypochlorite of lime. The former gives with aniline a deep-greenish or bluish-black precipitate; and the latter, an extremely beautiful violet-colored compound, the fine tint of which is, however, very soon destroyed.' In the manufacture of aniline on a large scale, several bases having higher boiling-points than aniline are formed. To one of these—a beautiful crystalline compound, represented by the formula C_6H_4, N_2 —the name of *Paraniline* has been given, from its being isomeric with aniline. Aniline is a substance of the greatest importance in theoretical organic chemistry, from the large number of derivatives and substitution-products which it yields, and for the knowledge of which we are almost entirely indebted to Hofmann, whose investigations originally appeared in a series of papers in the *Transactions of the Philosophical Society*. These compounds are, however, for the most part of too complicated a nature to be noticed in these pages. But, independently of its theoretical importance, this substance has recently been extensively employed in the arts, a series of pigments of unequalled beauty having been obtained from it by the action of oxidizing agents. It is to Mr. W. Perkin that we are indebted for the idea of applying practically the property possessed by aniline of forming violet and blue solutions with chromic acid and with hypochlorite of lime, to which we have already referred; and he succeeded in fixing these colors, and adapting them to the use of the dyer. The most important of these coloring matters are described in the article DYE-STUFFS (q. v.).

(4.) Trinitrophenic Acid [$HO, C_6H_2(NO_3)_3O$], in which three of the equivalents of the hydrogen of phenic acid are replaced by three equivalents of the group, NO_3 ; known also as Carbazotic Acid (q. v.) and Picric Acid. In addition to the remarks contained in the article on CARBAZOTIC ACID, it may be noticed that while a solution of this acid communicates a bright-yellow tint to animal textures, as the skin, wool, and silk, it has no such effect on tissues composed of vegetable fibres, such as cotton and linen, and hence it may be employed to ascertain whether the materials of any tissue belong to the animal or to the vegetable kingdom. A solution of a salt of this acid, when treated with indigo, yields a beautiful green color, which is employed in the manufacture of artificial flowers, and for various other purposes. In doses of from 1 to 10 grains, it acts on rabbits as a strong poison, occasioning convulsions and speedy death. It has been prescribed in small doses, with moderate success, in cases of intermittent fever; but patients to whom it is given should be previously informed that it possesses the property of giving to the eye a yellow and, as it were, a jaundiced appearance. All the salts of this acid are of a beautiful red or yellow tint, and most of them form brilliant crystals. When heated, or in some cases when only struck, they explode with considerable violence.

PHÉ'ON, in Heraldry, the barbed head of a dart. It is represented as engraved on the inner side, and its position is with the point downwards, unless otherwise blazoned.

PHÉ'RÆ, a powerful city of Thessaly, near Mount Pellon; according to legend, the ancient royal seat of Admetus and Alcestis; and afterwards of political consequence under 'tyrants' of its own, who long made their influence felt in the affairs of Greece, and repeatedly attempted to make themselves masters of Thessaly. One of these tyrants named Alexander, is particularly celebrated for his cruelties. It was one of his practices to bury innocent persons alive, and another to sow them up in the skins of wild beasts and set his hounds upon them. After a bloody reign of thirteen years, he was slain by his wife and her brother, 357 B.C. Five years later, P., with the rest of Thessaly, became subject to Philip of Macedon.—At P. there was a mineral spring, named Hyperia, famous for its healing virtues. A few ruins at Velesino still mark the site of the city.

PHEBECY'DÉS, an ancient Greek writer, born in the island of Syros, one of the Cyclades, in the 6th c. B.C. He is said by Diogenes Laertius to have been a rival of Thales, and to have learned his wisdom from the Egyptians and Chaldeans. He wrote

a Cosmogony in a kind of prose much resembling poetry, under the title *Heptamychos*, the meaning of which is doubtful. In a manner rather poetic than philosophic, he endeavored in this work to show the origin of all things from three eternal principles, *Time* or *Kronos*; *Earth*, as the formless and passive mass; and *Aether* or *Zeus*, as the formative principle. He taught the doctrine of the existence of the human soul after death; but it is uncertain if he held the doctrine of the transmigration of souls, afterwards promulgated by his disciple, Pythagoras. Of his work, only fragments are extant, which have been collected and elucidated by Sturtz (Gera, 1798; 2d ed., Leip. 1824.—Another P., who lived in the 5th c. B.C., compiled the mythical histories of Athens and other states, but, except a few fragments, the work is lost. See Sturtz, *Pherecydis Fragmenta* (Leip. 1824).

PHIGALIAN MARBLES, the name now given to the sculptured frieze taken from the cella of the temple of Apollo at Phigalia in Arcadia in 1814, and transferred to the British Museum. It represents the contests between the Centaurs and Lapithæ. The Phigalian temple of Apollo is, next to the Theseum at Athens, the most perfect architectural ruin in all Greece; but owing to its sequestered position at the head of a lonely and rocky glen among the Arcadian hills, it long remained unknown in modern times, except to the shepherds of the district; and to the same circumstance it probably owes, in part, its preservation. Chandler first visited and described it in 1765; he was followed by Gell, Dodwell, and others; and in 1812 it was very carefully examined by a body of artists and scholars, the results of whose investigations are given in Stackeberg's *Der Apollo-tempel zu Bassä in Arkadien* (Rome, 1826). The temple is built of a hard yellowish-brown limestone, stands north and south, was originally about 125 feet long and 48 broad, and had 15 columns on either side, and 6 on either front, in all 42, of which 36 still remain.

PHILADELPHIA, the chief city and seaport of Pennsylvania, U.S., and the second city in population and importance in America, is situated on the west bank of the Delaware River, at the mouth of the Schuylkill, on a plain 2 to 4 miles wide between the two rivers; lat. 39° 56' 59" N., long. 75° 9' 54" W.; 125 miles north-east of Washington, 87 miles south-west of New York. Its greatest length is 22 miles, its breadth is from 5 to 10 miles, and its area 129 miles. The city is neatly but plainly built of red bricks and marble, with fine squares laid out as parks. The picturesque eminence of Fairmount, with its reservoirs of water raised from the Schuylkill, and the Laurel Hill and other ornamental cemeteries, are favorite public resorts. Among the finest edifices are the Girard (formerly United States) Bank, Custom-house, Mint, the Public Ledger Building, the City Hall, and the buildings of the Girard College, most of them built of white marble, the last in the Corinthian style, having cost 2,000,000 dollars. The most noted building is Independence Hall, occupied in the revolution of 1776 by the Continental Congress, in which was voted and signed the Declaration of Independence. The Philadelphia Library, founded by Benjamin Franklin, contains 100,000 vols., and the Mercantile Library has 135,000. P., in fact, possesses some of the most valuable libraries in the U.S. The Academy of Fine Arts has, in connection with it, a gallery exhibiting upwards of 1000 pictures. For the Centennial Exhibition, held here in 1876, a main building 1876 feet long, with numerous and extensive supplementary halls and galleries, was erected in Fairmount Park at a cost of about 4,500,000 dollars.

The medical schools of P. have long been held in high esteem, and attract every year a large body of students. There are 6 medical colleges; 15 other colleges (one entitled a university); more than 40 hospitals—3 for the insane, 1 for deaf-mutes, and one for the blind; 91 charitable and benevolent institutions; besides numerous literary, scientific, and art associations; Bible, tract, and missionary offices and agencies. The Girard College, a free school for orphans, founded by Stephen Girard, a Philadelphia merchant, supports and educates 550 boys, on a foundation of 8,000,000 dollars. The Masonic Temple is a remarkable building. P. is in point of area the largest city in the U. S. In Fairmount Park is the first established Zoological Garden in the States. Next to New York, P. is the largest publishing center in the U. S., issuing very numerous daily and weekly papers, and other publications. Of its 500 churches, about 100 are Presbyterian and nearly as many Episcopal, Methodists and Baptists coming next. There are only 15 Friends' meeting-houses. Of about 50 banks, 30 are national. From its excellent water supply and nearness to available coal-fields, P. has risen to be the first manufacturing city in the Union, both as regards the number of persons employed, and the extent and variety of its manufactures; bread-stuffs and petroleum are the chief exports. P. owns the only American lines of iron steam-ships which ply between America and Europe. The assessed value of real and personal property is about \$600,000,000. Pop. (1840) 93,665; (1870) 674,022; (1880) 847,170.

The site of P. was discovered in 1623 by the Dutch of New York who settled there; they were followed by the Swedes in 1638. When the Settlement of the Delaware fell under English authority, P. was laid out in 1682 by William Penn, on 'a spot that seemed to have been appointed for a town,' and of which he wrote, 'Of all places in the world, I remember not one better seated.' Its early settlers were mostly of the Society of Friends. In 1684 it had 2500 inhabitants. It grew rapidly by large immigrations from Germany and the North of Ireland. In 1719 was here printed the first American newspaper, the *Weekly Mercury*. In 1728 was established the *Gazette*, afterwards edited by Franklin. The first colonial congress met here in 1774; in 1777 the town was occupied by the British forces under General Lord Howe, when the city contained 21,767 inhabitants. It was the seat of the United States bank, the capital till 1800, and the first city in America, until surpassed by New York.

PHILÆ, the name of a celebrated island lying in the midst of the Nile, south of Syene, beyond the frontier of Egypt, in 24° 1' 28" N. lat. It was called by the Egyptians Menlak, the place of the Cataract; or *Mennab*, the Abaton or Sanctuary; and by the Copts, Pilak or 'Cataracts.' It is a small granite rock, about 1000 feet long, and 200 feet broad, on which is placed a suite of buildings, not of the most remote antiquity, but distinguished for great architectural beauty. The oldest of these, consisting of a hypæthral or roofless hall, was built in the reign of Nectanebus I., 377—357 B.C. A second mention of the same monarch occurs on the first propylon, where a door, constructed in his reign, has been incorporated into the constructions by a later Ptolemy. Both these are dedicated to the goddess of Isis, who in P. was venerated as Athor or the Egyptian Venus. The principal remains consist of the great temple of Isis, erected by Ptolemy II. or Philadelphus, and continued by his successors, especially by Ptolemy III., Euergetes, 247—222 B.C.

The temple consists of a shrine or sekos, a pronaos, an open portico, and two pylons or gateways. Both of the propylons were constructed by Ptolemy VII., or Philometer, and Lathyrus; but the first was added to by Ptolemy IX., or Euergetes II., 145—141 B.C. On the second pylon, the monarch is represented slaying the hostile nations. The colonnade was principally erected by Tiberius. The charming little temple, the Mastabat el Pharaoun, or Pharaoh's Bed of the Arabs, was made in the reign of Trajan, 100 A.D. The temples are particularly important as containing the principal representations of the story of Osiris, his birth, bringing up, death, and embalmment by Isis. Commenced in the reign of Nectanebus I., and continued by the Ptolemies and Romans, the worship of Isis lingered here till 453 A.D., or sixty years later than the edict of Theodosius. After the subjection of the Blemmyes to the Nubian Christians, the temple was converted into a church, and the paintings daubed with mud; and, in 577 A.D., the bishop Theodorus changed the pronaos of the temple of Isis into the church of St. Stephen; and a Coptic church, at a later period, was built out of the ruins. The whole area of the ancient temple was about 435 feet long by 135 broad, in the center of the dromos. At the present day the island is deserted. It is a favorite resort of travelers ascending to Nubia, and is one of the best of the remaining ruined sites of ancient Egypt.

Pliny, N. H., v. c. 20; Servius, *Æneid*, v. 154; Jones and Goury, *Views on the Nile*; Wilkinson, *Modern Egypt*, ii. 295—308; Brugsch, *Reiseberichte aus Ägypten*, p. 256; Lepsius, *Reise*, p. 262.

PHILANTHROPY, a word formed from the Greek, and signifying the 'love of mankind.' In the history of German school education it has acquired a special meaning. The influence exercised by Rousseau was not less great on education than on politics, and was as visible in the pedagogues of Germany and Switzerland as in the men of the French Revolution. It is to the brilliant and one-sided advocacy by the author of *Emile*, of a return to nature in social life and in the training of the young, that Basedow owed his novel and enthusiastic educationalism. A brief notice of the institution, which was opened under his auspices at Dessau in 1774, and which was called *Philanthropin*, is given in the article on Basedow. Other establishments of the same kind were founded in different parts of Germany, but the only one which still survives is Salzmann's Institute at Schnepfenthal, in Gotlin, opened in 1784.

PHILEMON AND BAUCIS, according to a classic myth, finely poetized by Ovid in his *Metamorphoses*, were a married pair, remarkable for their mutual love. Jupiter and Mercury, wandering through Phrygia in human form, were refused hospitality by every one, till this aged pair took them in, washed their feet, and gave them such humble fare as they could provide. On going away, the gods took them with them to a neighboring mountain, on looking from which they saw their village covered with a flood, but their own cottage changed into a splendid temple. Jupiter permitted them to make any request they chose, but they only asked to be servants of his temple, and that they might die at the same time. When, accordingly, they were seated at the

door of the temple, being now of great age, they were changed, Philemon into an oak, and Baucis into a linden. They felt the change taking place, and as long as the power remained with them, looked most tenderly upon one another.

PHILEMON, EPISTLE OF PAUL TO, is the shortest of the four extant letters which the apostle wrote from Rome during his captivity. We either directly learn, or legitimately infer from its contents, that Philemon, who probably lived at Colosse, was a man of considerable wealth, the head of a numerous household, and liberal to the poor. He had possessed a slave called Onesimus, who had run away from him, after—it has been thought (verse 18)—robbing or defrauding him. Onesimus, however, coming to Rome, had been brought into contact with Paul, and converted to Christianity. At first the apostle thought to retain him as his personal attendant, for he was now, as he tells us (verse 9), 'Paul the aged'; but on further consideration, he resolved to send him back to his former master. The epistle is simply a brief letter, begging Philemon to pardon Onesimus, and to receive him 'not now as a servant, but above a servant, a brother beloved.' It exhibits an exquisite tenderness and delicacy of feeling, with all that tact and subtlety of address, by which Paul was wont to find his way into the innermost heart of men. The historical evidence of its authenticity is complete. Even Baur has remarked that modern criticism in assailing this particular book runs a greater risk of exposing itself to the imputation of an excessive distrust—a morbid sensibility to doubt and denial—than in questioning the claims of any other epistle ascribed to Paul.

PHILIDOR, the assumed name of a French family, which has produced many distinguished musicians, and one celebrated composer. The real name of the family was **DANIGAN**, and the additional appellation **P.** was assumed by Michael Danigan, the hautboist to Louis XIII., on account of his having equalled a celebrated player on the same instrument, named Filidori. The name was transmitted to his descendants, the most famous of whom was his grandson **FRANÇOIS ANDRÉ DANIGAN**, who was born at Dreux, in the department of Eure et Loir, 1726, studied music, and produced a great many comic operas, all long forgotten. It may be noticed that, while residing in London—whither he had fled on the outbreak of the revolution—(1779), he set to music the 'Carmen Sæculare' of Horace, a work which is considered by many as a masterpiece of musical art. He died in London, 31st August 1795. **P.**'s modern reputation rests exclusively on his skill in the game of chess, the principles of which he has laid down with exceeding clearness. It was in great measure his passion for this game which prompted him to visit Germany and Holland, where at that time the most distinguished players were to be found, in order to measure his strength with theirs. He was one of the founders of the London Chess Club. Here it was that in 1777 he published his *Analyse du Jeu des Échecs* (Analysis of the Game of Chess). One principle, then unique, seems to lie at the root of all **P.**'s games—i. e., to maintain and support carefully the pieces in the center of the board—and rather than deviate from this principle, he rejects the opportunity of making an effective and advantageous move. He practised with success the playing of games blindfold; but in this particular he has been far surpassed in recent times by Harwitz, and more recently by Morphy.

PHILIP II., king of Macedonia, and father of Alexander the Great, was born at Pella in 382 B.C. He was the youngest son of Amyntas II. and Eurydice. At Thebes, whither he was taken as a hostage by Pelopidas, he spent part of his early life, employing his exile in studying the art of war, and the constitution and laws of the Greek states, as well as the literature and the character of the people—pursuits which were of the greatest service to him afterwards, when called on to administer the government of the Macedonian kingdom. The assassination of his eldest brother, Alexander II., by Ptolemy Alorites, after a short reign of two years (369–367 B.C.), and the death of his second brother, Perdicas III., in battle (360 B.C.), placed him at the head of affairs in Macedonia, as guardian to his nephew Amyntas, still an infant. In a few months, **P.** made himself king, the rights of Amyntas being set aside. Dangers soon beset him from without and from within. The Illyrians and other neighboring tribes assailed his kingdom on different sides; while two pretenders to the throne, urged on by the Athenians and Thracians, stirred up civil commotion. But foreign and domestic enemies soon disappeared before the decision, the energy, and the wise policy of the young king. In the brief space of a year he had secured the safety of his kingdom, and had gained for himself a dreaded name. At this time he was only 24 years of age. Henceforward his policy was one of aggression, and his every thought was directed to the extension of his empire and the spread of Macedonian influence. The Greek towns on the coast of Macedonia were the first objects of attack. After possessing himself of Amphipolis and Pydna, by means little consistent with the faith of treaties, he handed

over to the Olynthians the city of Potidæa, which he had taken from the Athenians.

In Thrace he captured the small town Crenides, which, under its new name, **PHILIPPI**, soon acquired great wealth and fame, and ultimately became celebrated in profane as well as in sacred history. The surrounding district was rich in gold-mines, which proved a source of great revenue to **P.** (about, say, £250,000 annually), and supplied him plentifully with the means of paying his armies, of bribing traitorous Greeks, and of opening the gates of many cities, the sieges of which might otherwise have cost the blood of thousands. After a few years of comparative leisure, he turned his ambitious views southward; and capturing Methone (at the siege of which he lost an eye), he advanced into Thessaly, and ultimately to the Strait of Thermopylæ, which, however, he did not attempt to force, as it was strongly guarded by the Athenians. He therefore returned into Macedonia, and directed his arms against the Thracians, waiting for a more fitting occasion to carry out his darling project. Such an opportunity was not long wanting. After capturing all the towns of Chalcidice—the last of which was the important city of Olynthus—he made peace with the Thracians, and next year with the Athenians, who had been at war with him in defence of their allies the Olynthians. It was this siege of Olynthus by **P.** which called forth these Olynthiac orations of Demosthenes, which are still admired as efforts of oratorical genius hitherto unequalled in any country.

P. was now requested by the Thebans to interfere in the war ('the Sacred War') which was raging between them and the Phocians. He marched into Phocis, destroyed its cities, and sent as colonists to Thrace many of the inhabitants (346 B.C.). The place which the Phocians had occupied in the Amphictyonic Council was transferred to **P.**, and he was appointed, jointly with the Thebans and Thessalians, as president of the Pythian games. His next step was to secure a footing in the Peloponnese, by espousing the cause of the Argives, Messenians, and others, against the Spartans. In 339 B.C. the Amphictyonic Council declared war against the Locrians of Amphissa; and in the following year, appointed **P.** commander-in-chief of their forces. The Athenians were alarmed at his approach into Greece in this capacity, and formed a league with the Thebans against him; but their united army was utterly defeated at the battle of Chæronea (338 B.C.), and all Greece was at the feet of the conqueror. He was now in a position to enter on the great dream of his later years—viz., to invade the Persian empire, and revenge the injuries of Greece. Deputies from the different states of Greece assembled in congress at Corinth; and after resolving to make war on the Persian king, chose **P.** as leader of their armies. Preparations were in progress for this great expedition when he was suddenly cut off by the hand of the assassin Pausanias, at a festival celebrating the marriage of his daughter with Alexander of Epirus (336 B.C.). A private grudge at **P.**, for neglect to punish an insult offered to Pausanias by Attalus, was said to be the motive which inspired the murderer, though suspicion is not wanting that the deed was done at the instigation of Alexander and his mother Olympias, who had retired from the court in disgust at **P.**'s marriage, the year previous, with Cleopatra, daughter of Attalus, one of his generals.

P. was a man given to self-indulgence and sensuality; he was faithless to the observance of treaty obligations, and unscrupulous as to the means by which he gained his ends; but he had to deal with factious and faithless opponents, which may help to explain, if it does not justify his policy; while his clemency as a victor has won the admiration even of the virtuous Cicero, who pronounces him 'always great.' Of his force and energy of character, his acuteness, fertility of invention and eloquence, it is impossible to speak too highly. He was at the same time a lover of learning, and a liberal patron of learned men. He reigned from 359 to 336 B.C.

PHILIP III., OF MACEDON. On the death of Alexander the Great at Babylon in 323 B.C., the army elected as king, under the name of Philip III., Arrhidæus, son of Philip and Philinna of Larissa, one of his many wives. He was a youth of weak understanding, and was totally unfit for the duties of government. His wife Eurydice (daughter of Amyntas, son of Perdicas III.), whom he married in 322 B.C., endeavored, on their return to Macedonia, to oppose the measures of Polysperchon and Olympias in support of the young Alexander; posthumous son of Alexander the Great and Roxana. But her army was defeated; she herself was taken prisoner; and, along with her husband, was put to death in 317 B.C.

PHILIP II., KING OF SPAIN, the only son of the Emperor Charles V. (q. v.) and Isabella of Portugal, was born at Valladolid, 21st May 1527. He was brought up in Spain, and carefully educated under the superintendence of able tutors, by whose instructions he greatly profited, becoming an accomplished linguist and mathematician, and a connoisseur in architecture and the fine arts. But all attempts to indoctrinate him with the chivalric ideas

of the time were utterly futile. From his very childhood he was distrustful and reserved; he invariably spoke with slowness and an air of deep reflection which was too marked to be wholly real, and exhibited in his manners a *sang-froid* which even in his early years was rarely disturbed by ebullitions of passion. While still very young he was intrusted, under the direction of a council, with the government of Spain, and in 1543 he espoused Mary of Portugal, who died three years after. In 1548 he went to join his father at Brussels, and there adopted the multitudinous equipage and minute and pompous etiquette of the late Burgundian court, which from this time he retained. While at Brussels, P. was presented to his future subjects, and was at the same time fully initiated into his father's policy, the two chief items of which were the maintenance and extension of absolute rule throughout his dominions, and the support and propagation of the Catholic religion. In 1554 he married Mary Tudor, Queen of England, and to gain the support of that country to his political projects, and at the same time restore it to the Roman Catholic pale, he laid aside his ordinarily cold and haughty demeanor, and labored to ingratiate himself with his wife's subjects, taking the utmost care to avoid exciting the national jealousy of foreign influence. But his plans were discovered and frustrated, and this disappointment, combined with the annoyance to which he was subjected by the jealousy of his wife, prompted him to leave England (which he did for ever), and return to Brussels (September 1555).

In the following month he became, by the abdication of his father, the most powerful potentate of Europe, having under his sway, Spain, the Two Sicilies, the Milanese, the Low Countries, Franche Comté, Mexico, and Peru; his European territories being more fertile, and their inhabitants more wealthy and prosperous, than any others on the continent, while his army was the best disciplined, and headed by the greatest generals of the age. The treasury alone was deficient, having been drained by the enormous expenditure of his father's wars. P. was eager to begin the crusade in favor of Catholicism, but he was compelled to postpone it, owing to a league which had been formed between France, the Pope, and the Sultan, to deprive him of his Italian dominions. He soon got over his religious scruples at engaging in warfare with the pope, and intrusted the defence of the Sicilies to Alva (q. v.), who speedily drove out the pope and the French, and conquered the papal territories, while P. himself vigorously prosecuted the war against France in the north, and defeated the French at St. Quentin (q. v.) (August 10, 1557) and Gravelines (July 13, 1558). These reverses forced the French (the pope having already made a separate treaty) to agree to terms of peace at Chateau-Cambresis (April 2, 1559). P.'s wife was now dead, and after an unsuccessful attempt to obtain the hand of her successor, Queen Elizabeth, he espoused Isabella of France, and returned to Spain, where from this time he always resided. Before leaving the Low Countries, he solemnly promised to withdraw almost the whole of his Spanish troops who preyed upon the peaceful Flemings, but he firmly refused to annul or modify the rigorous edicts of his father against heretics.

His realm being now at peace, he resolved, as a necessary preliminary to the carrying out of his great proselytizing scheme, to replenish his treasury, a thing impossible without forced contributions, which, at that time, could only be obtained in those countries over which he held absolute rule—viz., Spain and America. He therefore set about establishing absolute government in those of his states that were in possession of something like free institutions, and with this view sought to introduce the Inquisition into the Low Countries and Italy. But the introduction of this instrument of tyranny was successfully resisted in Naples and the Milanese; in Sicily its powers were so shackled as to render it quite a harmless institution; but these failures only stimulated him the more to establish it in all its pride and power in the Low Countries. For a number of years it continued in vigorous action in that country; but the natural result of such a course of conduct was a formidable rebellion of all classes, Catholic and Protestant, which was partially successful—the northern portion (the 'seven united provinces') establishing its independence in 1579. In this conflict the resources of Spain were largely expended, and to replenish his treasury in the speediest manner possible, P. exacted enormous contributions from Spain, abolishing all special communal or provincial privileges and rights which might interfere with his actions, and suppressing all insurrection and discontent by force of arms or the Inquisition. During the first half of his reign he engaged in a desultory warfare with the Barbary corsairs, who were supported by the Turks—the only memorable incident of which was the famous naval victory of Lepanto (q. v.), won September 16, 1571.

In 1580 the direct male line of Portugal having become extinct, P. laid claim to the throne, and after the Duke of Alva had occupied the kingdom with an army, the Spanish monarch's title was recognized by the Portuguese estates. His enmity to England on account of the anti-Spanish policy of Queen Elizabeth in-

cited him to attempt the conquest of that country, but his most formidable attempt failed signally. See ARMADA. After the accession of Catharine de Medicis to power, France and Spain drew closer the bonds of amity which had previously subsisted between the two countries; but the refusal of Catharine to adopt P.'s plans for the wholesale slaughter of heretics produced a coolness in their relations. However, when Henry, king of Navarre, a Huguenot, became heir-presumptive to the throne, P. allied himself with the Guises and the other chiefs of the Catholic party who were in rebellion, and his obstinate persistence in these intrigues after the cause of the Guises was shown to be hopeless, prompted Henry to declare war against him. The Spaniards had the worst of it, and P. was glad to conclude the treaty of Vervins (2d May 1598). He died in the Escorial at Madrid, on 13th September of the same year. It cannot be denied that P. was gifted with great abilities, but he was also a visionary, especially in politics, and engaged in so many grand enterprises at once as to overtask his resources without leading to any good or profitable result. No single kingdom in Europe could have long stood against him, but he was always at war with at least two at a time; and even the splendid opportunity which the extinction of the direct Capetian line in 1589 gave him for uniting France, Spain, and Portugal in one great monarchy, could not restrain this unfortunate peculiarity.

His fanatical enthusiasm for Catholicism, in which he was surpassed by no man who ever lived, and the zeal with which he persecuted all heretics through the Inquisition, combined with the odious tyranny of his secular government to degrade Spain, by breaking the proud and chivalrous spirit which had been the source of its pre-eminence among European nations, while his virulent persecutions of the industrious Moriscos, and his oppressive exactions, put a stop to the commerce of the country. By his fourth wife, Anne of Austria, he had a son, Philip III.

PHILIP V. king of Spain, and the founder of the Bourbon dynasty in that country, was the second son of the Dauphin Louis (son of Louis XIV.) of France, and was born at Versailles, December 19, 1683. The last king of Spain of the Hapsburg dynasty, Charles II., had successively promised the succession to the throne to Charles, archduke of Austria, the great grandson of Philip III. of Spain, and to P., then duke of Anjou, the son of his own eldest sister; but becoming cognizant of a secret treaty which had been agreed to between England, France, and Holland for the partition of Spain, he, to prevent the dismemberment of his kingdom, left by will the succession to P. of Anjou. France immediately seceded from the partition treaty, and, on the death of Charles II. in 1700, P., who was the favorite candidate among the Spaniards, with the exception of those in the eastern provinces, took possession of the kingdom (April 21, 1701); and, to gain over Savoy to his side, and thus create a diversion in Italy against Austria, he married Maria Louisa, daughter of Victor Amadeus. War almost immediately broke out between the rival claimants, Charles being supported by the 'grand alliance,' which included England, Austria, and Holland, and subsequently (January 1702) Prussia, Denmark, and Hanover (May 1703), Portugal, and (October 1703) Savoy. See SUCCESSION, WAR OF SPANISH.

The fortune of war was mostly on the side of the allies; but France and Spain carried on the contest heroically, and, though at great sacrifices, the throne was secured to P. by the peace of Utrecht (April 11, 1713). In the following year the queen died, and P. espoused Elizabeth Farnese of Parma, who immediately induced her husband to commit the reins of government to Alberoni (q. v.); in fact, so much was the weak-minded king under the influence of his talented young wife, that he granted everything she asked. 'He was,' says Sismondi, 'remarkable for good nature, he had few faults and as few virtues, his sentiments were just and honorable, but he was wholly deficient in energy; he had no taste for anything beyond devotional exercises and the chase; he was made to be governed, and he was so all his life.' Alberoni's adventurous foreign policy, which at first succeeded in restoring the Spanish rule in Sicily and Sardinia, brought down upon Spain the wrath of the Quadruple Alliance (France, England, Holland, and Austria), and war was only averted by his being dismissed; but his dismissal was really produced by his neglecting to further the queen's pet scheme of providing sovereignties in Italy for her sons, who seemed to have little chance of obtaining the throne of Spain. The strong bond of union which had hitherto subsisted between Spain and France was broken, in 1725, by the refusal of the regent of the latter country to fulfill certain matrimonial agreements; but four years afterwards the two countries joined with England and Holland against the emperor, and in 1731 P. took measures to recover the old Spanish possessions in Italy. The war which followed at last satisfied the queen by giving the kingdom of the two Sicilies to her son Charles (1736), but P. in attempting to obtain still greater advantages over Austria, was led into a war of which he was not destined to see the result. He died at Madrid, July 9, 1746.

PHILIPPE II., better known as **PHILIPPE AUGUSTE**, king of France, was the son of Louis VII. and Alix of Champagne, and was born in August 1165. He was crowned, in 1179, during the life of his father, succeeded him in 1180, and proved one of the greatest monarchs of the Capetian dynasty. His marriage with Isabella of Hainault, a descendant of the Carolingians, established more completely the right of his family to the throne of France. He first made war upon the Count of Flanders, to obtain the districts of Vermandois, Valois, Amienois, and Artois, which belonged to his wife, and, after various fortune, obtained Amienois and part of Vermandois at once, and the rest after the count's death in 1185. By the advice of St. Bernard (q. v.) he rigorously punished heretics, despoiled the Jews, absolving their debtors of all obligations, excepting one-fifth, which he transferred to himself; put down with vigor the numerous bands of brigands and priest-haters who devastated the country and burned the churches and monasteries, compelling their chief leader, the Duke of Burgundy, to submit (1186) to his authority—acts which gave him great popularity among his subjects. He sustained the sons of Henry II. of England in their rebellions against their father, and conquered, in conjunction with Richard Cœur-de-Lion, many of the English possessions in France. After the accession (1189) of Richard to the throne, P. and he set out together on the third crusade; but quarrelled while wintering in Sicily, and this dissension continuing, P., after a sojourn of 3½ months in Syria, set out (31st July 1190) on his return to France, after taking a solemn oath to respect the integrity of Richard's dominions; but no sooner had he returned than he entered into an arrangement for the partition of Richard's territories in France with his unworthy brother John. Some acquisitions were made, but Richard's sudden return overset the calculations of the conspirators, and a war immediately commenced between the two monarchs, in which P. had at one and the same time to defend his territories from the English, and the Counts of Champagne, Boulogne, Bretagne, and Hainault, who attacked them on all sides.

In order to obtain money he was obliged to rescind his edicts against the Jews; but the mediation of Pope Innocent put an end (13th January 1199) to a war which was productive of no other result than the exhaustion of the strength of the combatants. Richard of England died within two months after; but war almost immediately recommenced with England, regarding the respective claims of King John of England and his nephew Arthur of Bretagne to the French heritage of Richard Cœur-de-Lion, which consisted chiefly of Anjou, Maine, and Touraine. Arthur had applied for aid to P., and the French king immediately responded by causing the young duke to be recognized in the above-mentioned provinces; but a quarrel in which he became involved with the pope on account of his having divorced his second wife, Engelburga of Denmark, to marry Agnes of Meran, a Tyrolese princess, compelled him to leave the English in possession for a little time longer. The defeat, capture, and subsequent murder of Arthur, however, again brought him into the field. The English provinces in France were attacked by the combined French and Bretons; Normandy and Poitou, with the three disputed provinces, were annexed to France; and the English dynasty in Bretagne dispossessed by a French one (26th October 1206). During 1211—1214, P. was engaged in a war with King John of England and the Emperor Otho of Germany, who had leagued themselves against him, in which he was on the whole successful. During the rest of his reign, P. was occupied in consolidating his new possessions, and took no part either in the war with the Albigenes or that in England, though his son Louis (q. v.) went to the latter with an army.

P. succeeded in establishing the unity of his dominions, and in emancipating the royal authority from the trammels of the papacy and clergy, and vindicated his sovereign authority over the latter as his subjects, irrespective of the pope. His measures, without alienating the greatest feudal lords, tended firmly to establish his authority over them, and to emancipate the larger towns from their sway. To increase the unity of the kingdom, and strengthen the central power, he established at Paris a chamber of twelve peers, six lay and six ecclesiastical, who almost always supported his plans, even against the court of Rome. Finally, he largely improved and embellished Paris, built many churches and other institutions, and encouraged commercial associations; he also fortified many of the chief towns, including the capital. He died at Mantes, July 14, 1223.

PHILIPPE IV., surnamed *Le Bel* or 'Fair,' king of France, the son of Philippe III., king of France, and Isabella of Aragon, was born at Fontainebleau in 1268, and succeeded his father in 1285. By his marriage with Queen Joanna of Navarre, he obtained Navarre, Champagne, and Brie. For several years he carried on a struggle with the Count of Flanders to obtain possession of that country, and also seized Guienne from the English; but was, in the end, obliged to restore Guienne and Flan-

ders beyond the Lys. The great events of P.'s reign were his war with the papacy and the extermination of the Knights Templars; the former had its origin in the attempt of the king to tax the clergy as well as the laity for the heavy expenses of his numerous wars. Boniface forbade the clergy to submit to taxation, while P., on his side, ordered that neither money nor valuables were to be exported, thus cutting off a main supply of papal revenue; and on the pope's legate insolently reprimanding him, he threw him into prison.

P. now called an assembly of states, in which deputies of towns appeared—though not for the first time—and obtained assurance of their support, even in case of excommunication and interdict. Boniface, in turn, assembled a council at Rome (1302), which supported his view, and the celebrated bull, *Unam Sanctam* (q. v.) was issued. P. refused the bull to be publicly burned, and with the consent of the states-general confiscated the property of those prelates who had sided with the pope. Boniface now excommunicated him, but the king, nothing daunted, sent to Rome his general, William de Nogaret, who seized and imprisoned the pope; and though he was released after a few days by a popular rising, he soon afterwards died. In 1304, P. obtained the elevation of one of his own creatures to the papal chair as Clement V., on condition of his residing at Avignon, and giving up the Knights Templars (q. v.). In accordance with this agreement, the Templars were seized (1306—1314), and burned by hundreds, and their wealth appropriated by Philip. The grandmaster, Jacques Molay, was burned, 18th March 1314, and when dying he summoned P. to appear within a year and a day, and the pope within forty days, before the judgment-seat of God; strange to say, both the pope and king died within the time mentioned, the latter at Fontainebleau, November 29, 1314. P. during his whole reign steadily strove for the suppression of feudalism and the introduction of the Roman law; but while thus increasing the power of the crown, and also that of the third estate, he converted royalty, which was formerly protecting, kind, and popular to the mass of the people, into a hard, avaricious, and pitiless taskmaster. Under him the taxes were greatly increased, the Jews persecuted, and their property confiscated; and when these means were insufficient to satisfy P.'s avarice, he caused the coinage to be greatly debased; yet he was an able monarch, and under him France was extended almost to its present limits on the north and east.

PHILIPPE VI., or **VALOIS**, king of France, was the son of Charles of Valois, younger brother of Philippe IV., and succeeded to the regency of France on the death of Charles IV., the proclamation of a king being deferred on account of the pregnancy of Charles IV.'s widow; but on her giving birth to a daughter, P. caused himself to be crowned king at Reims (May 29, 1328), and assumed royal authority. His right to the throne was denied by Edward III. of England, the grandson of Philippe IV., who declared that females, though excluded by the Salic law, could transmit their rights to their children, and therefore insisted upon the superiority of his own claims. P. however, was not only already crowned king, but he had the support of the people. His reign commenced gloriously, for marching into Flanders to support the court against his rebellious subjects, he wiped out the disgrace of Courtrai by vanquishing the Flemings at Cassel (August 23, 1328). He was obliged to give up Navarre (q. v.), as the Salic law of succession did not apply to it, but he retained Champagne and Brie, paying for them a considerable annual stipend. P. seems to have had no settled plan of government, and no systematic political action; his acts were regulated by the whim of the hour, and were mostly calculated to gratify his own vanity and love of show. From 1330 to 1336, constant encroachments had been made upon the English possessions in France, till at last Edward III.'s patience was exhausted; and, on August 21, 1337, he formally declared war, and a commencement of this terrible hundred years' contest was made both in Guienne and Flanders; it was carried on languidly for several years, the only prominent incident being the destruction of the French fleet off Sluys (June 24, 1340).

In March 1343, P. established the 'gabelle,' or monopoly of salt, a heavy percentage tax on all mercantile transactions. The constant round of fêtes and tournaments at court was never interrupted, even when the war had well-nigh exhausted the wealth of the country, for the money to carry them on was immediately provided by some new tax or fresh confiscation. In 1346, Edward III. landed in Normandy, ravaged the whole country to the environs of Paris, and totally defeated P. at Crécy (q. v.). A truce was then concluded, but the devoted kingdom had no sooner been released from war, than destruction in another and a more terrible form, that of the 'Black Death' (q. v.), threatened it. The wild extravagance of the court was nothing lessened by this visitation; but the financial embarrassments in which P. found himself, compelled him to agree to the passing of a law (1338) which gave to the assembly of the states the sole power of imposing

taxes. He received Dauphiné in gift in 1349, purchased Majorca from its unfortunate king, and died August 22, 1350, neither loved nor respected. He was a despoiler of learning, and a bigot.

PHILIPPE LE HARDI (*Philip the Bold*), the founder of the second and last ducal house of Burgundy, was the third son of Jean, king of France, and his wife Bonne of Luxemburg, and was born January 15, 1342. He was present at the battle of Poitiers (1356), and displayed such heroic courage, venturing his own life to save that of his father, as gained for him the sobriquet of *le Hardi*, or 'the Bold.' He shared his father's captivity in England, and on returning to France in 1360, received in reward of his bravery the duchy of Touraine, and subsequently (1363) also that of Burgundy, being created at the same time the first peer of France. On the accession of his brother, Charles V., to the throne of France, P. had to resign Touraine, but, as a compensation, obtained in marriage, Margaret, the heiress of Flanders.

In 1372, he commanded the French army opposed to the English, and took from them many of their possessions. In 1380, he exerted himself to suppress the sedition of the Flemish towns against their count, and succeeded with some of the malcontents; but the citizens of some of the populous places, especially Ghent, were possessed with such a fever of independence, that after many fruitless attempts to induce them to return to their allegiance, P. raised an army, and inflicted upon them the bloody defeat of Rosebeck (November 27, 1382), leaving 26,000 of them on the field. Flanders, the county of Burgundy, Artois, Rethel, and Nevers fell to him by the death of the count in 1384, and the influence of his power, combined with prudence and good management on his part, soon won the affection and esteem of his new subjects. Energy and wisdom characterized his government; arts, manufactures, and commerce were much and judiciously encouraged, and his territory (a kingdom in extent) was one of the best governed in Europe. During the minority and subsequent imbecility of his nephew Charles VI. of France, he was obliged to take the helm of affairs, and preserve the state from insurrection and sedition within, and the attacks of the English without. He was on his way to repel an attack of the latter on Flanders when he died at the chateau of Hall in Brabant, a little to the south-west of Brussels, April 27, 1404.

PHILIPPE LE BON, i. e., 'the Good,' Duke of Burgundy, the son of Jean 'Sans-peur' by Margaret of Bavaria, and grandson of Philippe the Bold, was born at Dijon (the capital of the duchy), June 13, 1396, and on the assassination of his father on the bridge of Montreau at the instigation of the dauphin (afterwards Charles VII.), succeeded to the duchy of Burgundy. Bent on avenging the murder of his father, he entered into an offensive and defensive alliance with Henry V. of England at Arras in 1419, at the same time recognizing him as the rightful regent of France, and heir to the throne after Charles VI.'s death. This agreement, which disregarded the Salic law, was sanctioned by the king, parliament, university, and states-general of France by the treaty of Troyes, but the dauphin declined to resign his rights, and took to arms; he was, however, defeated at Crevant (1423) and Verneuil (1424), and driven beyond the Loire. Some disputes with the English prompted P. to conclude a treaty with the king of France in 1429. However, the English, by ceding to P. the province of Champagne, and paying him a large sum of money, restored him to their side. At this time, by becoming heir to Brabant, Holland, Zealand, and the rest of the Low Countries, he was at the head of the most flourishing and powerful realm in Western Europe; but though much more powerful than his superior, the king of France, he preferred to continue in nominal subjection. Smarting under some fresh insults of the English viceroy, and being strongly urged by the pope, he made a final peace (1435) with Charles, who gladly accepted it even on the hard conditions which P. prescribed. The English, in revenge, committed great havoc among the merchant navies of Flanders, which irritated P. to such an extent that he declared war against them, and, in conjunction with the king of France, gradually expelled them from their French possessions.

The imposition of taxes, which were necessarily heavy, excited a rebellion, headed, as usual, by the citizens of Ghent, but the duke inflicted upon them a terrible defeat (July 1454), though he wept over a victory bought with the blood of 20,000 of his subjects. The latter part of his reign was filled with trouble caused by the quarrels between Charles VII. and his son, the Dauphin Louis (afterwards Louis XI.), who had fled from his father's court, and sought shelter from P., although, after ascending the throne, far from showing gratitude, he tried, in the most dishonorable manner, to injure his benefactor. P. died at Bruges, July 15, 1467, deeply lamented by his subjects. Under him, Burgundy was the most wealthy, prosperous, and tranquil state in Europe; its ruler was the most feared and admired sovereign of his time, and his court far surpassed in brilliancy those of his contemporaries. Knights and nobles from all parts of Europe flocked to his jousts and tournaments.

PHILIPPEVILLE, a thriving town and seaport of Algeria, in the province of Constantine, and forty miles north-north-east of the city of that name, on the Gulf of Stora, between Cape Boujaroun and Cape de Fer. It was laid out in 1833 by Marshal Valée, on the ruins of the ancient Russiada, and is one of the prettiest towns in Algeria, and thoroughly French in its character. It is an important entrepôt of the commerce of the east of Algeria, and the country in the vicinity is picturesque and fertile, producing grain, tobacco, cotton, flax, and fruits. It contains numerous public offices, a large hospital and dispensary, Catholic and Protestant churches, public library and museum, theater, &c. In the vicinity are quarries of the famous Filfila marble. A harbor has been constructed, including a pier and dock, which afford shelter to small merchant ships in bad weather. There are here several establishments for curing fish, and trade is carried on in grain and in fabrics of native manufacture. P. is the chief station of the railway for the province of Constantine, and is connected by steamer with Marseille and Algiers. Pop. (1872) 13,022.

PHILIPPI, a city of Macedonia. It was named after Philip II. of Macedon, who conquered it from Thrace (up to which time it had been called Crenides, or the 'Place of Fountains'), and enlarged it because of the gold-mines in its neighborhood. Philip worked the mines so well, that he got from them 1000 talents a year. It is famous on account of the two battles fought in 42 B.C. between Antony and Octavianus on the one side, and the republicans under Brutus and Cassius on the other. The first engagement was undecided; in the second, 20 days after, the republic finally perished. The apostle, Paul founded a Christian church here in 53 A.D., to which one of his epistles is addressed. The ruins of the city still bear the name of Philippi, or Feliba.

PHILIPPIANS, EPISTLE TO THE, one of the latest of the Pauline epistles. It was transmitted, from Rome probably about the year 63 A.D., through Epaphroditus, apparently a pastor of the Philippian church, who had been sent to minister to the necessities of the apostle. The Philippian church was looked upon with peculiar tenderness and affection by Paul. It was the first fruits of his evangelization in Europe; its members were singularly kind towards him; again and again, when he was laboring in other cities, such as Thessalonica and Corinth, they sent him contributions that he might not be burdensome to his new converts, and now they had sent one of the brethren all the way to Rome with presents for him, knowing that he was in bonds, and suspecting—that was in fact the case—that he might be in sore straits for his daily bread. His letter to them is deeply affecting. It contains not so much of doctrinal matter, as of a warm outpouring of his personal feelings towards his friends at Philippi. The historical evidence in favor of the authenticity of the Epistle is so strong, that it could hardly give way to any internal criticism; and the objections of this kind, urged by Baur, Schweigger, and others of the Tübingen school, who regard it as a Gnostic composition of the 2d c., are regarded as preposterous even by many Biblical scholars who do not profess to be orthodox.

PHILIPPICS, originally the three orations of Demosthenes against Philip of Macedon. The name was afterwards applied to Cicero's orations against the ambitious and dangerous designs of Mark Antony. It is now commonly employed to designate any severe and violent invective, whether oral or written.

PHILIPPINE ISLANDS, lie to the north of Borneo and Celebes, in 5° 30'—19° 42' N. lat., and 117° 14'—126° 4' E. long. They are more than 1200 in number, with an area of about 150,000 square miles. Pop. (1876) 6,173,632, three-fourths of whom are subject to Spain, the remainder governed, according to their own laws and customs, by independent native princes.

Luzon, in the north, has an area of 51,300 square miles, and Mindanao, or Magindanao, in the south, fully 25,000. The islands lying between Luzon and Mindanao are called the Bissayas, the largest of which are—Samar, area 13,020 square miles; Mindoro, 12,600; Panay, 11,340; Leyte, 10,080; Negros, 6300; Masbate, 4200; and Zebu, 2352. There are upwards of a thousand lesser islands of which little is known. To the south-west of the Bissayas lies the long, narrow island of Paragao or Palawan, formed of a mountain-chain with low coast-lines, cut with numerous streams, and exceedingly fertile. The forests abound in ebony, log-wood, gum-trees, and bamboos. Area 8820 square miles. To the north of Luzon lie the Batanen, Bashee, and Babuyan islands, the two first groups having about 8000 inhabitants, the last unpeopled.

The Sooloo Islands form a long chain from Mindanao to Borneo, having the same mountainous and volcanic structure as the P. I., and all are probably fragments of a submerged continent. Many active volcanoes are scattered through the islands; Mayon, in Luzon, and Buhayan, in Mindanao, often causing great devastation. The mountain-chains run north and south, and never attain a greater elevation than 7000 feet. The islands have many rivers, the coasts are indented with deep bays, and there are many lakes in the interior. Earthquakes are frequent and destructive,

Manila, the capital, having been nearly destroyed by one in 1863. In 1864, another terrific earthquake visited Mindanao, destroying most of the houses. Three successive earthquakes in 1880 did great damage, especially in Manila, where many buildings were totally ruined. The soil is fertile, except where extensive marshes occur. In Mindanao are numerous lakes, which expand during the rainy seasons into inland seas. Rain may be expected from May to December, and from June to November the land is flooded. Violent hurricanes are experienced in the north of Luzon and west coast of Mindanao. Especially during the changes of the monsoons, storms of wind, rain, thunder and lightning prevail. The weather is very fine, and heat moderate, from December to May, when the temperature rapidly rises and becomes oppressive, except for a short time after a fall of rain. The fertility of the soil and humid atmosphere produce a richness of vegetation which is nowhere surpassed. Blossoms and fruit hang together on the trees, and the cultivated fields yield a constant succession of crops.

Immense forests spread over the P. I., clothing the mountains to their summits; ebony, iron-wood, cedar, sapau-wood, gum-trees, &c., being laced together and garlanded by the bush-rope or palasan, which attains a length of several hundred feet. The variety of fruit-trees is great, including the orange, citron, bread-fruit, mango, cocoa-nut, guava, tamarind, rose-apple, &c.; other important products of the vegetable kingdom being the banana, plantain, pine-apple, sugar-cane, cotton, tobacco, indigo, coffee, cocoa, cinnamon, vanilla, cassia, the areca-nut, ginger, pepper, &c., with rice, wheat, maize, and various other cereals.

Gold is found in river-beds and detrital deposits, being used in form of dust, as the medium of exchange in Mindanao. Iron is plentiful, and fine coal-beds, from one to four feet thick, have been found. Copper has long been worked in Luzon. There are also limestone, a fine variegated marble, sulphur in unlimited quantity, quicksilver, vermilion, and saltpetre—the sulphur being found both native and in combination with copper, arsenic, and iron.

Except the wild cat, beasts of prey are unknown. There are oxen, buffaloes, sheep, goats, swine, harts, squirrels, and a great variety of monkeys. The jungles swarm with lizards, snakes, and other reptiles; the rivers and lakes with crocodiles. Huge spiders, tarantulas, white ants, mosquitoes, and locusts are plagues which form a set-off to the beautiful fire-flies, the brilliant queen-beetle (*Blater noctiluca*), the melody of myriads of birds, the turtle-doves, pheasants, birds of paradise, and many lovely species of paroquets, with which the forests are alive. 'Hives of wild bees hang from the branches, and alongside of them are the nests of humming-birds dangling in the wind.'

The caverns along the shores are frequented by the swallow, whose edible nest is esteemed by the Chinese a rich delicacy. Some of them are also tenanted by multitudes of bats of immense size. Buffaloes are used for tillage and draught; a small horse for riding. Fowls are plentiful, and incredible numbers of ducks are artificially hatched. Fish is in great abundance and variety. Mother-of-pearl, coral, amber, and tortoise-shell are important articles of commerce.

The Tagals and Bisayers are the most numerous native races. They dwell in the cities and cultivated lowlands; 2,500,000 being converts to Roman Catholicism, and a considerable number, especially of the Bisayers, Mohammedan. The mountain districts are inhabited by a negro race, who, in features, stature, and savage mode of living, closely resemble the Alfours of the interior of Papua, and are probably the aborigines driven back before the invasions of the Malays. A few of the negroes are Christian, but they are chiefly idolaters, or without any manifest form of religion, and roaming about in families, without fixed dwelling. The Mestizos form an influential part of the population; by their activity engrossing the greatest share of the trade. These are mostly of Chinese fathers and native mothers. Few Spaniards reside in the P. I., and the leading mercantile houses are English and American. The Chinese exercise various trades and callings, remaining only for a time, and never bringing their wives with them. The principal languages are the Tagalese and Bisayan. Rice, sweet potatoes, fish, flesh, and fruits form the food of the Tagals and Bisayers, who usually drink only water, though sometimes indulging in cocoa-wine. Tobacco is used by all. They are gentle, hospitable, fond of dancing and cock-fighting.

With the exception of two Spanish brigades of artillery and a corps of engineers, the army is composed of natives, and consists of seven regiments of infantry and one of cavalry. There is also a body of Spanish militia in Manila, whom the governor, as commander of the naval and land forces, may call out in an emergency. The navy has four steamships, one brig, six gun-boats, and a great number of feluccas for coast service. Education is far behind, and similar to what it was in Europe during the middle ages. There is an archbishop of Manila, and bishops of New Segovia, Nueva Caceres, and Zebu. Religious processions are the pride of the people, and are formed with great parade,

thousands of persons carrying wax-candles, &c. The natives not only build canoes, but ships of considerable tonnage. They weave various textile fabrics of silk, cotton, abaca, and very fine shawls and handkerchiefs from the fibre of pine-apple leaves. These are called pinas, and often sell for one or two ounces of gold apiece. The pinilian is the finest sort, and is only made to order—one for the queen of Spain costing 500 dollars. They work in horn, make silver and gold chains, fine hats and cigar-cases of fibres, and beautiful mats of different colors, ornamented with gold and silver. The governor-general is appointed direct from Spain, and resides at Manila. There are also a lieutenant-governor, governors of provinces and chiefs of pueblos or townships, who are elected yearly. Acting governors reside also at Zamboanga in Mindanao, and Iloilo in Panay. They are appointed for six years by the governor-general.

It is to be remembered that all the ports of this archipelago, except Sual, Iloilo, Zebu, and Manila, are still closed against foreign vessels. In 1868, there seemed a gleam of hope that a more liberal commercial policy would be adopted by Spain for their possessions among the Philippine Islands. In that year it was decreed that differential duties should be abolished in April 1871. They were abolished accordingly, but only for three months. In July an order was issued granting importers, under the Spanish flag, of foreign goods, an advantage of 2½ per cent. The value of the imports into the United Kingdom for the P. I. and Ladrones in 1880 was £1,688,663; of our exports thither, £1,328,482. The total exports from the P. I. in 1877 were valued at £3,592,900; of which Great Britain got £1,239,000; India, £80,000; Hong-Kong, £40,000. The imports for 1876 were £2,397,432, the duties on which amounted to 7½ per cent. on their value. The principal exports are sugar, tobacco, cigars, indigo, Manila hemp, or Abaca (q. v.), coffee, rice, dye-woods, hides, gold-dust, and bees-wax. Cotton, woolen, and silk goods, agricultural implements, watches, jewelry, &c., are imported. British and American merchants do the largest business, the imports from Great Britain being about £1,000,000 per annum.

The Sooloo islands have a population of 150,000; are governed by a sultan, whose capital is Suig, in 66° 1' N. lat., and 120° 55' 51" E. long., who also rules over the greatest part of Paragoa, the northern corner only being subject to Spain.

Luzon has a population of 2,500,000, one-fifth part being independent; the Bissayas islands, 2,000,000, of whom three-fourths are under Spanish rule. The population of Panay amounts to 750,000, and that of Zebu to 150,000. Of the numbers in Mindanao nothing is known; the districts of Zamboanga, Misamis, and Caragan, with 100,000 inhabitants, being all that is subject to Spain. The greater part of the island is under the sultan of Mindanao, resident at Selanga, in 7° 9' N. lat. and 124° 38' E. long., who, with his feudatory chiefs, can bring together an army of 100,000 men. He is on friendly terms with the Spaniards. Besides Manila, there are very many large and important cities, especially in Luzon, Panay, and Zebu. The great centers of trade are Manila in Luzon, and Iloilo in Panay.

The P. I. were discovered in 1521 by Magellan, who, after visiting Mindanao, sailed to Zebu, where, taking part with the king in a war, he was wounded, and died at Mactan, 26th April 1521. Some years later the Spanish court sent an expedition under Villalobos, who named the islands in honor of the Prince of Asturias, afterwards Philip II. For some time the chief Spanish settlement was on Zebu; but in 1581 Manila was built, and has since continued to be the seat of government.

PHILIPPINS, a Russian sect, so called from the founder, Philip Pustosviät, under whose leadership they emigrated from Russia in the end of the 17th c., are a branch of the RASKOLNIKS (q. v.). They call themselves Starowerski, or 'Old Faith Men,' because they cling with the utmost tenacity to the old service-books, the old version of the Bible, and the old hymn and prayer-books of the Russo-Greek Church, in the exact form in which these books stood before the revision which they underwent at the hands of the patriarch Nikon in the middle of the 17th century. There are two classes of the Raskolniks—one which recognizes popes (or priests); the other, which admits no priest or other clerical functionary.

The P. are of the latter class; and they not only themselves refuse all priestly ministrations, but they regard all such ministrations—baptism, marriage, sacraments—as invalid; and they rebaptize all who join their sect from other Russian communities. All their own ministerial offices are discharged by the Starik, or parish elder, who for the time takes the title of pope, and is required to observe celibacy. Among the P. the spirit of fanaticism at times has run to the wildest excesses. They refuse oaths, and decline to enter military service; and having, on account of this, and many other incompatibilities of the system, with the Russian practice, encountered much persecution, they resolved to emigrate. Accordingly, in 1700, under the leadership of Philip Pustosviät, they settled partly in Polish Lithuania, partly afterwards in East

Prussia, where they still have several small settlements with churches of their own rite. They are reported to be a peaceable and orderly race. Their principal pursuit is agriculture; and their thrifty and industrious habits have secured for them the goodwill of the proprietors.

PHILIPS, AMBROSE, was born in Shropshire in 1675. He studied at St. John's College, Cambridge, and took his degree of M.A. in 1700. In 1709 his Pastorals appeared, along with those of Pope, in *Tonson's Miscellany*; and the same year, having gone on a diplomatic mission to Copenhagen, he addressed from thence a 'Poetical Letter' to the Earl of Dorset, which was published, with a warm eulogium from Steele, in the *Tatler*. In 1712, he brought on the stage *The Distressed Mother*, a tragedy adopted from Racine's *Andromaque*, which had great success. He subsequently wrote two other tragedies, but they proved failures. Some translations from Sappho, which appeared in the *Spectator*, added greatly to P.'s reputation, but Addison is believed to have assisted in these classic fragments.

Some exaggerated praise of P. having appeared in the *Guardian*, Pope ridiculed his pastorals in a piece of exquisite irony, which led to a bitter feud between the poets. P. even threatened personal chastisement, and hung up a rod in Button's Coffee-house, but no encounter took place. One of the names fastened upon P. was that of 'Nambly Pamby,' arising from a peculiar style of verse adopted by him in complimentary effusions, consisting of short lines and a sort of infantine simplicity of diction, yet not destitute of grace or melody. The accession of the House of Hanover proved favorable to the poet; he was appointed paymaster, and afterwards a commissioner of the lottery; and going to Ireland as secretary to Archbishop Boulter, he became secretary to the Lord Chancellor, M.P. for Armagh, and registrar of the Prerogative Court. He died in 1749. P. is somewhat conspicuous in literary history from the friendship of Addison and the enmity of Pope; but his poetry, wanting energy and passion, has fallen out of view.

PHILIPSTOWN, a market and post town (formerly the assize town) of King's County, province of Leinster, Ireland, 47 miles south-west from Dublin. Its charter dates from 1567; and in the reign of James II. it obtained the privilege of sending two members to parliament. This privilege was withdrawn at the Union. It is at present, and has long been a place of hardly any trade and entirely without manufacture, and the town has fallen still more into decay since the withdrawal of the assizes (1838) to the neighboring and more flourishing town of Tullamore. Pop. (1881) 829, principally Catholics.

PHILISTINES (*LXX.*, *Allophiloí*, Strangers), a word either derived from a root *phalasa* (*Ætli.*), to emigrate, wander about, or identified with *Pelagi* (q. v.), or compared by others with *Shefela* (Heb.), lowlanders; designates a certain population mentioned in the Bible as being in frequent contact with the Jews, and who lived on the coast of the Mediterranean, to the south-west of Judæa, from Ekron towards the Egyptian frontier, bordering principally on the tribes of Dan, Simeon, and Judah. Our information about the origin of the P. is extremely obscure and contradictory. The genealogical table in Genesis (x. 14) counts them among the Egyptian colonies (the 'Casluhim, out of whom came Philistim'); according to Amos ix. 7, Jeremiah xlvii. 4, and Deuteronomy ii. 23, they came from Caphtor. But supposing that the Casluhim were some separate tribe, and yet Caphtorian colonists, the question still remains, whether Caphtor can be identified with Cappadocia in Asia Minor, as the early versions (*LXX.*, *Targ.*, *Pesh. Vulg.*) have it; or whether it be Pelusium, Cyprus, or the Isle of Crete. The latter opinion seems not the least probable among them. At what time they first immigrated, and drove out the Canaanitish inhabitants, the Avvim, is difficult to conjecture. They would appear to have been in the country as early as the time of Abraham; and in the history of Isaac, Abimelech, king of Gerar, is distinctly called king of the Philistines. Yet, even supposing that in Genesis the country is designated by the name which it bore at a later period, there can yet be no doubt of the people being firmly established at the time of Moses (Exodus xv. 14, &c.). Thus the date of their immigration would have to be placed at about 1800 B.C.

At the Exodus, Moses, evidently fearing an encounter with the warlike colony for his undisciplined band, did not choose the shorter way to Canaan through their territory, but preferred the well-known circuitous route. At a later period, however, Joshua, having triumphed over 81 Canaanite princes, also conceived the plan of making himself master of the possessions of the P.; but his intended disposal of their country for the benefit of the tribe of Judah was never carried out. At this time, they were subject to five princes (Seranin = axes, pivots), who ruled over the provinces of Gaza, Ashdod, Ascalon, Gath, and Ekron. Not before the period of the Judges did they come into open collision with the Israelites; and the strength and importance in which they

suddenly appear then, contrast so strangely with their insignificance at the time of the patriarchs, that many theories—a double immigration principally—have been propounded to explain the circumstance. We find them daring powerful nations like the Sidonians, whom, about 1209 B.C., they forced to transfer their capital to a more secure position on the island of Tyre; or the Egyptians, with whom they engaged in naval warfare at the same time under Rameses III. With the Israelites their war assumed the air of guerrilla raids, sometimes into the very heart of the country. Under Shamgar (about 1370 B.C.), they were repulsed with a loss of 600 men; however, about 200 years later, the Israelites were tributary to them, and continued to groan under their yoke, with occasional pauses only, until Samson first commenced to humiliate them. But they were still so powerful at the time of Eli, that they carried away the ark itself. Under Samuel, their rule was terminated by the battle of Mizpah.

Saul was constantly engaged in warding off their new encroachments, and at Gilboa, he and his sons fell in a disastrous battle against them. At this time, they seem to have returned to their primitive form of a monarchy, limited, however, by a powerful aristocracy, the king's formal title again being 'Abimelech' = 'Father-king,' as we find it in Genesis. David succeeded in routing them repeatedly; and under Solomon their whole country seems to have been incorporated in the Jewish empire. The internal troubles of Judæa emboldened the P. once more to open resistance. Under Joram, in union with the Arabians, they invaded Judæa, and not only carried away the royal property, but also the serail and the royal children. Uzziah, however, recovered the lost ground; he overthrew them, and dismantled some of their most powerful fortresses—Gath, Yabne, and Ashdod, and erected forts in different parts of their country. Under Ahaz, they rose again, and attacked the border-cities of the 'plain' on the south of Judah; and a few years later, renewed their attacks, in league with the Syrians and Assyrians. Hezekiah, in the first years of his reign, subjected their whole country again, by the aid of the Egyptians, whom we find in the possession of five cities. The Assyrians, however, took Ashdod, under Tartan, which was retaken again by Psammetich, after 29 years' siege. About this time, Philistæa was traversed by a Scythian horde on their way to Egypt, who pillaged the temple of Venus at Ascalon. In the terrible struggles for supremacy which raged between the Chaldeans and Egyptians, Philistæa was the constant battle-ground of both—her fortresses being taken and retaken by each of them in turn; so that the country soon sank into ruin and insignificance. Yet a shadow of independence seems to have been left to it, to judge from the threats which Zechariah (ix. 5), after the exile, utters against Gaza and Ascalon, and their pride.

In the time of the Maccabees, the P. were Syrian subjects, and had to suffer occasionally from the Jews, although inter-marriages between the two nations were of no rare occurrence. Alexander Balas transferred part of the country to Judæa; another part was taken by Alexander Jannæus; Pompey incorporated some of the cities with Roman Syria; Augustus transferred another portion to Herod; and finally, Salome, his sister, received a small principality of it, consisting of Jamnia, Ashdod, and Ascalon. But by this time the name of the country had long been lost in that of Palestine, which designated all the territory between the Lebanon and Egypt.

Of their state of culture, institutions, &c., we know very little indeed. They appear as a civilized, agricultural, commercial, and warlike nation. They trade largely, and their wares seem to have been much sought after. Their worship was much akin to that of the Phœnicians—a nature-religion, of which Dagon, Ash-taro, Baalzebub, and Derceto were the chief deities. Priests and soothsayers abounded; their oracles were consulted even by people from afar. They carried their charms about their persons, and their deities had to accompany them to the wars. They do not seem to have practised circumcision. As to their language, so little is known about it, that conjectures seem more than usually vain. Those who take them to have been Semites, conclude that their language, too, was Semitic; others, who would identify them with the Pelasgians, differ also respecting their language. Thus much is certain, that their proper names, as they are recorded in the Bible, are mostly Semitic, and that there always remained a difference of dialect between the Hebrew and the Philistæan idiom.

The name of Philistines is given by German students to all non-students in general, and the citizens of the special university-place in particular.

PHILLIP, JOHN, R.A., was born, 22d May 1817, at Aberdeen. At a very early age he gave indication of the talent which afterwards so distinguished him; and before he had attained his fifteenth year, had painted various pictures showing his feeling for color. He thus procured an introduction to the late Lord Panmure, by whom he was enabled to go to London to pursue his studies. He began by copying from the Elgin marbles at the

British Museum, and after a few months was admitted as a student at the Royal Academy.

All his early subjects were of Scotch character, such as a 'Scotch Fair,' 'Baptism in Scotland,' a 'Scotch Washing,' 'The Offering,' &c. In the year 1851 he went to Spain in search of health, which he found, and with it a change in the character of his subjects. On his return home he established himself at the head of the painters of the habits and customs of the Spanish people. In 1853 he exhibited at the Royal Academy 'Life among the Gipsies at Seville.' His pictures for 1854—1855, 'A Letter Writer of Seville,' and 'El Paseo,' were both purchased by Her Majesty the Queen. In 1857, he attained the rank of Associate of the Royal Academy, and the following year exhibited a most powerful picture of 'Spanish Contrabandistas,' which was purchased by the late Prince Consort, of whom he also painted a portrait the same year for the town-hall of his native city. In 1859, he received the full honor of Royal Academician. His work for exhibition in 1860 was certainly the most difficult he had yet tried, and his success was proportionably great. 'The Marriage of the Princess Royal' was pronounced by both his fellow-artists and the public as a decided success. His next portrait subject (exhibited 1863) was, if possible, a still more difficult task, being the 'House of Commons, 1860,' containing upwards of thirty portraits of the leading members of both sides of the House; in it he was equally successful. However much he excelled in portraiture, his heart was more in his Spanish subjects, of which he was understood to have in progress more works (the fruits of his last two visits to Spain) than he could have finished in several years.

The characteristics of Mr. P.'s style are rich powerful color, broad light and shade, strong bold outline, and great variety and truthfulness of texture; there was no artist in his day who had more power over his brush, or whose example produced a greater effect on the colorists of the present British school. He died February 27, 1867.

PHILIPPO'POLIS, chief town of the recently organized province of Eastern Roumelia, Turkey, 91 miles W.N.W. from Adrianople. It stands on a small island formed by the Maritza, which here becomes navigable. This island rises as a hill in the midst of a vast plain, which extends beyond Adrianople on the east, and from the base of the Rhodope Mountains on the south, to the Balkan chain on the north. The plain is extremely fertile, and is celebrated for the excellence of the rice which it produces. P. carries on a very extensive commerce both with Austria and with the East. P. is an ancient town, and in the time of the Romans bore the name of *Trinontium*. Three-fifths of the inhabitants are Christians, one-fifth Jews and gipsies, the remainder Mohammedans. P. is the seat of a Greek archbishop. The North American Board of Missions has a station at Philippopolis. Pop. about 60,000.

PHILIPPSBURG, a town of the grand-duchy of Baden, 16 miles north from Carlsruhe, on the right bank of the Rhine, at the mouth of the Salzbach. In former times it was one of the most important fortresses on the Rhine, and belonged to the Bishop of Spire. During the Thirty Years' War, P. fell successively into the hands of the Swedes, the French, the Imperialists, and again of the French, who were confirmed in possession of it by the Peace of Westphalia. In the wars of Louis XIV., it was taken by the Germans, and assigned to Germany by the peace of Nimeguen in 1679; but was again taken in 1688 by the French under Vauban, and once more restored to Germany by the peace of Ryswick in 1697. The French captured it again in 1734, and relinquished it in 1735. During the wars of the French Revolution, P. was bombarded, taken, and its fortifications completely destroyed in 1800. Pop. 2317.

PHILO JUDÆ'US, the *Philosopher* (there being another Jewish Greek writer of this name), was born at Alexandria, about the time of the birth of Christ. Belonging to one of the most wealthy and aristocratic families—his brother was the Alabarch Alexander—he received the most liberal education; and, impelled by a rare zeal for learning, he, at a very early age, had passed the ordinary course of Greek studies which were deemed necessary for one of his station. Although every one of the different free sciences and arts included in the *Encyclopædia*, he says, attracted him like so many beautiful slaves, he yet aimed higher, to embrace the mistress of them all—Philosophy. Metaphysical investigation was the only thing which, according to his own confession, could give him anything like satisfaction or pleasure. The extraordinary brilliancy of his style, which, by his contemporaries, was likened to that of Plato—his rare power of thought and imagination, and an erudition which displayed the most astonishing familiarity with all the works of the classical Greek poets and philosophers, while at the same time it made him an adept in the fields of history, geography, mathematics, astronomy, physiology, natural history, music, &c.—could not but be of vast influence both upon his co-religionists and those beyond the pale of his ancestral creed. He had com-

pletely mastered the literature of his nation; but, strange to say, he chiefly knew it, as far as it was Hebrew, from translations. Thus, the Bible was only familiar to him through the Septuagint version, with all its shortcomings. When about 40 years of age, he went to Rome as the advocate of his Alexandrian brethren, who had refused to worship Caligula in obedience to the imperial edict. He has left an account of this embassy, into the result of which we need not enter here. Of his life we know little except what is recorded above, and that he once went to Jerusalem. His second mission to Rome, to the Emperor Claudius, on which occasion he is said to have made the acquaintance of the Apostle Peter, as reported by Eusebius, is doubtful.

The religious and philosophical system of P., however, which is really the thing of most consequence, is most minutely known, and is deserving of the profoundest study, on account of the vast influence which it has exercised both on the Jewish and Christian world. To understand his system aright, it will be necessary to remember the strange mental atmosphere of his days, which we have endeavored briefly to sketch in our introduction to Gnostics (q. v.). The Alexandrines had endeavored to make Judaism palatable to the refined Greeks, by proving it to be identical with the grandest conceptions of their philosophers and poets, and had quite allegorized away its distinctive characteristics. P. was the first man who, although himself to a great extent imbued with allegorizing tendencies, made a bold and successful stand against a like evaporation of the revealed religion of his fathers: which, indeed, in many cases had led people to throw off its yoke also outwardly. A most zealous champion of Judaism, his bitterness in rebuking those co-religionists who tried to defend their secret or overt apostasy by scoffing at the Law itself, who were 'impatient of their religious institutions, ever on the look-out for matter of censure and complaint against the laws of religion, who, in excuse of their ungodliness, thoughtlessly argue all manner of objections'—knows no bounds. He cannot understand how Jews, 'destined by divine authority to be the priests and prophets for all mankind,' could be found so utterly blind to the fact, that that which is the position only of a few disciples of a truly genuine philosophy—viz., the knowledge of the Highest, had by law and custom become the inheritance of every individual of their own people; whose real calling, in fact, it was to invoke the blessing of God on mankind, and who, when they offered up sacrifices 'for the people,' offered them up in reality for all men.

To P., the divinity of the Jewish Law is the basis and test of all true philosophy. Although, like his contemporaries, he holds that the greater part of the Pentateuch, both in its historical and legal portions, may be explained allegorically, nay, goes so far even as to call only the Ten Commandments, the fundamental rules of the Jewish theocracy, direct and immediate revelations, while the other parts of the Book are owing to Moses: he yet holds the latter to be the interpreter specially selected by God, to whose dicta in so far also divine veneration and strict obedience are due; and again, although many explanations of a metaphysical nature could be given to single passages, yet their literal meaning must not be tampered with. This literal meaning, according to him, is the essential part, the other explanations are mere speculation—exactly as the Midrash and some Church Fathers hold. Only that allegorical method differed in so far from that of his contemporaries, that to him these interpretations—for which he did not disdain sometimes even to use the numbers symbolically, or to derive Hebrew words from Greek roots, and the like—were not a mere play of fancy, in which he could exercise his powers of imagination, but, to a certain extent, a reality, an inner necessity. He clung to philosophy, as combined with the Law. If the former could be shown, somehow or other, to be hinted at in the latter, then only he could be that which all his soul yearned to be—viz., the disciple of both: a Greek, with all the refinement of Greek culture; and a Jew—a faithful, pious, religious Jew. Nay, he even urged the necessity of allegory from the twofold reason of the anthropomorphism current in Scripture and from certain apparent superfluities, repetitions, and the like, which, in a record that emanated from the Deity, must needs have a special meaning of their own, which required investigation and a peculiar interpretation. See MIDRASH, HAGGADA. Yet this fanciful method never for one moment interfered with his real object of pointing out how Judaism most plainly and unmistakably was based upon the highest ethical principles.

His writings develop his ideas and his system in the two directions indicated. In that division of his writings principally, which treats of the Creation (*Kosmopoia*), he allows allegory to take the reins out of his hands; in that on the Laws (*Nomoi*), on the other hand, he remains remarkably sober and clear, extolling the Mosaic legislation throughout, at the expense of every other known to him. In a very few instances only he is induced to find fault, or to alter slightly, by way of allegory, the existing ordinances.

His idea of God is a pre-eminently religious, not a philosophical one. He alone is the real Good, the Perfect; the world has

only an apparent existence, and is the source of all evil. God is only to be imagined as the primeval light, which cannot be seen by itself, but which may be known from its rays, that fill the whole world. Being infinite and uncreated, He is not to be compared with any created thing. He has therefore no name, and reveals Himself only in designations expressive of this 'inexpressibility.' He is also named the Place (the talmudical *Makom*) because He comprises all space, and there is nothing anywhere besides Him. He is better than Virtue and Knowledge, better than the Beautiful and the Good (*Kalokagatheia*), simpler than the One, more blissful than bliss. Thus, He has, properly speaking, no quality, or only negative ones. He is the existing Unity or Existence itself (*On*, or *On*), comprised in the unpronounceable Tetragrammaton. As Creator God manifests Himself to man, and He is then called 'The Beginning, the Name, the Word, the Primeval Angel.' In this phase of active revelation of God, which is as natural to Him as burning is to the heat, and cold to the snow, we notice two distinct sides, the Power and the Grace, to which correspond the two names of Elohim and Adonai, used in the Bible.

The Power also gives the laws, and punishes the offender; while the Grace is the beneficent, forgiving, merciful quality. Yet, since there is not to be assumed an immediate influence of God upon the world, their respective natures being so different, that a point of contact cannot be found, an intermediate class of beings had to be created to stand between both, through whom He could act in and upon creation—viz., the spiritual world of ideas, which are not only 'Ideals,' or types, in the Platonic sense, but real, active powers, surrounding God like a number of attendant Beings. They are His messengers, who work His will, and by the Greeks are called good demons; by Moses, angels. There are very many different degrees of perfection among them. Some are immediate 'serving angels,' others are the souls of the pious, of the prophets, and of the people of Israel, who rise higher up to the Deity; others, again, are the heads and chief representatives of the different nations, such as Israel does not need, since they conceive and acknowledge the Everlasting Head of all beings, Himself. The *Logos* comprises all these intermediate spiritual powers in His own essence. See article LOGOS for P.'s views on this part of his system. Man is a microcosm, a little world in himself, a creation of Logos, through whom he participates in the Deity, or, as Scripture has it, 'he is created in the image of God.' He stands between the higher and lower beings—in the middle of creation. The ethical principles of Stoicism, P. identified with the Mosaic ethics, in which the ideal is most exalted moral perfectibility or sanctity, and man's duties consist in veneration of God, and love and righteousness towards fellow men. P. holds firmly the belief in immortality. Man is immortal by his heavenly nature; but as there are degrees in his divine nature, so there are degrees in his immortality, which only then deserves this name when it has been acquired by an eminence of virtue.

There is a vast difference between the mere living after death, which is common to all mankind, and the future existence of the perfect ones. Future recompense and punishment are not taken by him in the ordinary sense of the word. Virtue and sin both have all their rewards within themselves; but the soul, which is 'pre-existing,' having finished its course in the sublunar world, carries this consciousness with it in a more intense and exalted manner. Paradise is Oneness with God; there is no hell with bodily punishments for souls without a body, and no Devil in the Philonic system.—Philo's Messianic notions are vague in the extreme, and he partly even interprets certain scriptural passages alluding to some future Redeemer as referring to the soul. Yet he indicates his belief in a distant time when some hero will arise out of the midst of the nation, who will gather all the dispersed together; and these, purified by long punishments, will henceforth form a happy, sinless, most prosperous community, to which all the other nations will be eager to belong.

We have only been able to indicate, in the slightest of outlines, the principal features of P.'s theology and philosophy, without endeavoring to follow any one of the manifold systematic schemes into which his scattered half-obscure dicta have been pressed. The influence P. has exercised upon Christianity and Judaism (in the later writings of which his name occurs as 'Yedidiah the Alexandrine') is enormous, and the various articles in the course of this work (Gnosticism, Jews, Logos, &c.) dwell more or less upon this point. What he has done for the development of Philosophy, is discussed under that head, and in the articles PLATO, NEO-PLATONISM, &c.

Of the many works left under his name, several have been declared spurious, but in some cases without much show of reason. His writings are generally brought under three chief divisions, the first of which comprises those of a more general and metaphysical nature, such as, *De Mundi Incorruptibilitate, Quod Omnis Probus Liber, De Vita Contemplativa*. The second contains those written in defence of his compatriots, *Adversus Flaccum, Legatio ad Caicum, De Nobilitate*. The third and most important is de-

voted to the interpretation and explanation of Scripture in the philosophical manner indicated, *De Mundi Opificio, Legis Allegoriarum Libri III.*; containing also a number of special treatises, *De Circumcisione, De Monarchia, De Præmissis Sacerdotum, De Posteritate Caini, De Cherubim*, &c.; five books *On the History of Abraham, De Josepho, Vita Moysi, De Caritate, De Penitentia*, &c.; to which also belong *De Parentibus Colendis, De Virtute eiusque Partibus*, first published by A. Mai; and certain very doubtful fragments, first discovered in an Armenian translation, such as *De Providentia and De Animalibus*, &c. Many of his works, however, seem irredeemably lost. The *editio princeps* by Turnebus, dates Paris, 1552; reprinted Geneva, 1618; Paris, 1640; &c. Mangey published a more critical edition (Lond. 1742, 2 vols. fol.), and Richter a slightly improved one (Leip. 1828—1830, 8 vols.). An edition of Pfeiffer (1785, &c.) remained incomplete. Another edition was published by Tauchnitz (1851, &c.). As yet, there are several codd. in the Escorial, in Rome, in St. Petersburg, which have never been collated, and which promise, to judge from the few readings known, to furnish an immense help for that really critical edition, which as yet is a desideratum.—Of the scholars who have written on P., we mention principally Dahl, Bryant, Grfrörer, Creuzer, Grosmann, Wolff, Ritter, Beer, &c. The English translation of P. in 4 vols., forms part of Bohm's *Ecclesiastical Library*.

PHILOLOGY. This word, as a technical name for a branch of knowledge, has gone through various phases of meaning. Originally signifying the love of talk or discourse, and then, in a more restricted sense, the love of philosophical conversation such as is exhibited in the dialogues of Plato, it came, in the later period of Greek literature, to mean the study and knowledge of books, and of the history and other science contained in them. In this sense it passed over to the Romans, under whom the name of philologists was applied to men distinguished for universal learning, more especially to the *grammatici*, whose chief occupation of editing and illustrating the classic poets, naturally led them to this multifarious knowledge; and when Martianus Capella (q. v.) in the 5th c. composed his *Encyclopædia* (q. v.) or curriculum of education, embracing the 'seven liberal arts' (Grammar, Dialectic, Rhetoric, Music, Arithmetic, Geometry, and Astronomy), he designates the collective whole by the name of philology. What is known as the Revival of Literature after the dark ages, is nothing else than the revival of the ancient philology. But when men, instead of looking only at what had been written, began to examine the world for themselves, and enlarge the bounds of science, it became impossible for one man to cultivate the whole round of knowledge, and the term philology was by degrees restricted to a knowledge of the languages, history, laws, &c. of the ancient world (by which the Greek and Roman world was chiefly thought of), or, more narrowly still, to the study merely of the languages—of grammar, criticism, and interpretation. A more complete conception of philology, as an independent branch of knowledge, was that of F. A. Wolf, who assigned as its field all that belongs to the life of the ancient peoples; and the conception is still further extended by Böckh, who makes it almost synonymous with history—its problem being the reproduction of the past; in this sense, the word is applicable to all peoples at all periods of their history, so that we are beginning to have an Indian philology, a German philology, a Slavic philology, no less than a classic philology. The fullest and most systematic exposition of what philology in this sense ought to embrace, has been given by G. Haase in Ersch and Gruber's *Ency.*, 3d sect., vol. xxiii.

Of philology, even in its widest sense, the study of language was always, and necessarily, a fundamental part; and, in the usual sense of the word, it has been the chief part—often nearly the whole. For a long time after the revival of learning, the classic writers were studied chiefly for their language and style, and those of them that did not come up to an imaginary standard of purity were despised and neglected, however valuable they might be for their matter. But although great and even undue attention was thus given to language, it was only as an instrument, as means to an end. The philologist studied a language in order to be able to understand it and use it—to get at the thoughts conveyed in it, or to convey his own thoughts with force and elegance to others. This is the object of the grammars, dictionaries, annotated editions, and criticisms, which constitute the chief part of philological literature. But within recent years, philology has entered upon a new phase, or rather a new study has sprung up alongside of the old. As the naturalist investigates a class of objects not with a view to turn them to use, but to understand their nature, and classify them; so the new school of philologists examine and compare the structures of the various languages, and arrange them in classes and families, with the ultimate view of arriving at some theory of language in general—its mode of origin and growth. The comparison of the structure of two or more languages is called Comparative Grammar, and the whole of this

new branch of study is sometimes designated as Comparative Philology; but it seems better to leave the old field in possession of the old name, and in contradistinction to philology as the practical knowledge of languages, to speak of the study of language as a phenomenon *per se*, as the Science of Language. The German term *Sprachenkunde*, and the French *Linguistique*, have more especial reference to the naturalist, or classificatory aspect of the study.

So long as the view prevailed that language was a human invention, anything like a science of it was impossible. According to that view, which was early started, and was especially elaborated and discussed by Locke, Adam Smith, and Dugald Stewart, it was only after men found that their rapidly increasing ideas could be no longer conveyed by gestures of the body and changes of the countenance, that they set about inventing a set of artificial vocal signs, the meaning of which was fixed by mutual agreement. On this theory, there might be a history of the subsequent course of the different languages, but inquiries into the nature and laws of language after the manner of the physical sciences would be absurd. In opposition to the philosophers who attributed the origin of language to human invention, some theologians claimed a divine origin for it, representing the Deity as having created the names of things, and directly taught them to Adam. Both these theories may now be considered as given up by all who are entitled to speak on the subject. Everything, in fact, tends to show that language is a spontaneous product of human nature—a necessary result of man's physical and mental constitution (including his social instincts), as natural to him as to walk, eat, or sleep, and as independent of his will as his stature or the color of his hair.

Language was an object of speculation among the Greek philosophers; but as was the case with their inquiries into the outward world generally, they began at the wrong end; they speculated on the origin of things before they had examined the things themselves. They knew no language but their own, and all others were indiscriminately classed as 'barbarous' or foreign; they had no test of affinity among tongues except mutual intelligibility. The theories of the modern philosophers of the 18th c. were nearly as baseless; they were mere *a priori* speculations, akin to Burnet's (q. v.) 'theory of the earth,' which was constructed before the strata of the earth's crust had been explored. The great obstruction to the true course of inquiry was the assumption, first made by the Church Fathers, and for a long time unquestioned, that Hebrew was the primitive language of man, and that therefore all languages must be derived from Hebrew. A prodigious amount of learning and labor was wasted during the 17th and 18th centuries, in trying to trace this imaginary connection. Leibnitz was the first to set aside this notion, and to establish the principle that the study of languages must be conducted in the same way as that of the exact sciences, by first collecting as many facts as possible, and then proceeding by inductive reasoning. It was owing to his appeals and exertions that missionaries, travelers, and others, now began making those collections of vocabularies and specimens of languages and dialects which form the *Herbarium*, as it were, of human speech. A valuable Catalogue of Languages in six volumes was published in Spanish in 1800, by Hervas, a Jesuit missionary. It contains specimens and notices of more than 300 languages, and many of the true affinities are happily traced. A similar work was Adelung's *Mithridates* (4 vols. Berlin, 1806—1817), based on the catalogue of Hervas, and also on the collections which the Russian government had caused to be made.

In none of these efforts, however, although much truth was struck out, were there anything like fixed principles of scientific classification. The light that brought order into the chaos rose with the study of Sanscrit (q. v.), first made accessible to European scholars by Sir William Jones, Colebrooke, and other members of the Asiatic Society, founded in Calcutta in 1784. The similarity of Sanscrit to Greek and Latin, especially in the grammatical forms, struck every one with surprise. Sir William Jones declared that 'no philologist could examine the Sanscrit, Greek, and Latin without believing them to have sprung from the same source, which perhaps no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic had the same origin with the Sanscrit. The old Persian may be added to the same family.' Rather than admit this relation, which it was seen would involve also ethnological affinities, some, as Dugald Stewart, denied that Sanscrit had ever been the language of a people, and held that it was an invention of the Brahmins, who had constructed it on the model of the Greek and Latin. Fr. Schlegel's work, *On the Language and Wisdom of the Indians* (1808), although defective and erroneous in point of scholarship, has the merit of boldly embracing the languages of India, Persia, and Europe in one family group, by the comprehensive name of Indo-Germanic. It was this work that called the attention of German scholars to a field of labor which they have since made specially their own.

The successive publications of Bopp (q. v.), beginning in 1816, and culminating in his great work on the grammar of the Aryan languages, *Vergleichende Grammatik* (Berl. 1833—1852; a 2d ed. recast and enlarged, 3 vols., Berl. 1857; an English translation of 1st ed. was published in 3 vols., 1845—1850, and, revised, in 1854), created the new science of Comparative Grammar, and laid a sure and broad foundation for the science of language generally. Concurrent with the labors of Bopp, were those of Pott in his *Etymological Researches* (*Etymologische Forschungen*, 2 vols., 1833—1836; 2d ed. 1859) and other works. Not less important, though confined to one stock of the Aryan family, the Teutonic, was the Great German Grammar (*Deutsche Grammatik*, 4 vols., 1818—1837) of J. Grimm (q. v.). William von Humboldt (q. v.) did much to establish a philosophy of language—the relations and interactions of mind and speech; a department of the subject which has been further cultivated in recent years by Steinthal. The method of investigation, thus invented and perfected in the field of the Aryan tongues, has been applied to other languages, and considerable progress has been made in grouping the principal varieties of human speech into families, which again fall into subdivisions or branches, according to the different degrees of nearness in the relationship. In establishing these relationships, although a comparison of the vocabularies—the numerals, pronouns, and more essential nouns and verbs—may establish a general affinity, and render a common origin probable; yet the surer test lies in the grammatical forms. For when those elements of a language which express the relations of things—case, number, tense—have once become mere terminations, and lost their original form and independent meaning, they can only be transmitted by tradition; and when the same grammatical forms are found possessed in common by two or more tongues, they must be an inheritance from a common ancestor. It follows from this that the 'genealogical' classification, as it is called, cannot be carried out with great surety or rigor except in the case of languages in which grammatical forms had become in some degree fixed before their divergence—in other words, of the inflectional languages. Accordingly, the only two well-defined genealogical families are the Aryan and the Semitic, which embrace the whole of the languages of the inflectional type.

Besides the division of languages into families bearing traces of a common origin, there is a division into three orders, as they may be called, depending upon a radical difference of structure. Speech, as the expression of thought, contains two elements: ideas or conceptions, which constitute the substance or material part; and the relations of these ideas to one another, which constitute the formal part; and the nature of a language depends upon the particular way in which the vocal expression of these two elements is combined. At the foundation of all words lie Roots (q. v.), or simple sounds expressive of meaning. Now, some languages, as the Chinese (q. v.), use these roots in their naked form as words, the same syllable, according to its position, serving as noun, adjective, verb, &c.—e. g., *ta* means great, greatness, to be or to make great, greatly or very. The relational part of the thought, for the most part, gets no vocal expression, it is only indicated by position, as when *min*, people, and *li*, power, are simply put together (*min li*) to signify the people's power. Relations not readily indicated by position are expressed in a roundabout way by using additional significant words: thus, *tachung* (mass or multitude) *jin* (man) = men; *nü* (woman) *tsé* (child) = daughter; *y min li* (employ people power) = with people's power. Even in such cases, each root preserves its independence, and is felt to express its own radical meaning. Languages like the Chinese, whose development has been arrested at this rudimentary stage, are called *Monosyllabic* or *Isolating*.

The next stage of development is that of the *Agglutinating* languages, which are by far the most numerous, including the Turanian and American families. In these, the relational part of thought obtains prominent vocal expression by separate roots joined or *glued* on to the significant roots as terminations. These terminations were originally themselves significant roots, and many of them are still used as separate significant words, although the greater part have sunk down to mere signs of cases and other relations. The compound expression thus formed never, however, attains perfect unity; the significant root always remains rigid, unobscured in its sense and unchanged in form, and the termination is felt as something distinct from the body of the word.

Thus, the Finnish declension exhibits a structure of the most mechanical and transparent kind—e. g., *karhu*, bear; *karhu-n*, of the bear; *karhut-ta*, without bear; *karhu-sta*, out of the bear; and so on through fifteen cases. The insertion of the plural suffix, *t*, gives *karhu-i-n*, of the bears; *karhu-i-ta*, without bears; *karhu-i-sta*, out of the bears; &c. But this composite mechanical structure reaches its climax—remaining all the while perfectly transparent—in the Turkish verb. Thus, the root *se* has the indefinite meaning of loving, and the inf. is *se-mek*, to love; which then, by the insertion of certain suffixes, can take on as many as

forty forms or voices—e. g., *sev-me-mek*, not to love; *sev-e-me-mek*, not to be able to love; *sev-dir-mek*, to cause to love; *sev-dir-ish-mek*, to cause one another to love; *sev-il-mek*, to be loved; *sev-il-e-me-mek*, not to be able to be loved; &c. Each of these forms, then, runs through a large round of tenses and moods, with their persons and numbers.

The languages of the American Indians are all of this agglutinating type, although they have also got the name Incorporative, or Intercalative, because they run a whole phrase or sentence into one word—e. g., *hoponi*, to wash; *hopocuni*, to wash hands; *hopoaduni*, to wash feet; *ninacagua*, I (ni) eat (qua) flesh (naca). The Basque language partakes of this character.

It is only in the third or *Inflectional* stage that perfect unity of the two elements is attained. In the Aryan and Semitic tongues, which alone have reached this highest state of development, the significant root and the termination have become blended into one both in effect and form, and phonetic changes have for the most part obliterated the traces of composition. Yet no doubt is felt by philologists that the most highly organized of the inflecting or amalgamating languages began with the radical stage, and passed through the agglutinate. The analytic powers of comparative grammar have succeeded in tracing back the formal elements of the Aryan tongues to original independent words, agglutinated to other words to modify them. See INFLECTION. Against this theory it has been urged, that there is no historical instance of a language so changing its type, and passing from one stage to another. But a sufficient account of this phenomenon may be found in the different mental habits and political positions of the peoples (see Max Müller, *Lectures on the Science of Language*, First Series, page 316). Besides, the languages of the lower types do show a tendency, under favorable circumstances, to produce grammatical forms of the higher kind. Even in Chinese, in some of its modern dialects, something like cases is to be seen; and Finnish and Turkish, in contact with the inflected languages of Europe, are making approaches to the inflectional type.

On the other hand, the inflectional languages had, before the earliest times of which we have any written monuments, entered on the reverse phase—the *analytic*. By the process of phonetic change and decay, the grammatical forms have been gradually becoming obliterated and losing their power, and their place has been supplied by separate words, in the shape of prepositions and auxiliary verbs. See INFLECTION.

Connected with these radical differences of type, is one of the higher and more speculative problems of the science—the question as to the common origin of all languages. The inherent and apparently ineffaceable difference of structure in the three orders above described, as well as the absence of all sure marks of genealogical affinity even between the two families of the inflectional type, the Aryan and the Semitic, are considered by some as insuperable objections to the theory of a common origin. But although it may be fruitless to look for extensive identifications of the roots and grammatical forms of the Aryan tongues, even in the oldest forms to which we can trace them, with those of the Semitic, still more with Chinese or Turkish elements; it seems rash and unscientific to affirm that, going back to the radical stage, the development of all could not have begun from a common stock of monosyllabic roots. The wonderful transformations exhibited by language in the course of its known history, seem sufficient ground for maintaining the *possibility* of a common origin. On the other hand, the nature of the case forbids all hope of ever being able to *prove* it; for the coincidences that occur (e. g., Chinese *fu*, Tibetan *pha*, Lat. and Gr. *pa-ter*, Eng. *fa-ther*; Chin. *mu*, Egypt. *mu*, Lat. and Gr. *ma-ter*, Eng. *mo-ther*), even though they were much more numerous than they are, might well arise from the mind and vocal organs of man being everywhere essentially the same.

Languages, like living organisms, are in a state of continual flux or change, and an essential part of the science consists in investigating the laws according to which these changes take place. It is because there are such laws that a science of language is possible. In tracing words to their origin, and identifying them with words in other languages, we are no longer guided by mere similarity of sound; on the contrary, identity of sound is often a proof that a proposed etymology is wrong. It has been established, for instance, by induction (see GRIMM'S LAW), that *c* in Latin is regularly represented by *h* in Gothic and English; while for Gothic or English *c*, the corresponding letter in Latin is *g*. Accordingly, we readily recognize Latin *corn-u* and English *horn* as cognate words; while a suggestion to connect the English *corn* with *cornu*, is immediately rejected. If *corn* has a representative in Latin, it must begin with *g*, which points out *granum* as the word. *Grain* is not the English representative of *granum*; it is *granum*, borrowed from the Latin through the French. The expert etymologist can often identify with certainty two words, although not a letter remains the same. In simple cases, this is done by every one. Who, for instance, doubts that Aberdeen-shire *fa*, *filk*, are merely dialectic varieties of Eng. *who*, *which*.

Yet the same persons who readily admit such cases, are sceptical when it is proposed, for instance, to identify Fr. *larme*, with Eng. *tear*. The grounds of identification, however, are similar in both instances; the only difference being, that with regard to *larme* and *tear*, they require to be traced historically. No one will dispute that *larme* is a corruption of Lat. *lacrima*; in fact, it can be followed through the successive stages of change.

Now we know that the Romans had a peculiarity of letting *d* in some positions degenerate into *l*. Nor is this unaccountable, when we consider that the contact of organs which produces *d*, differs from that which produces *l*, chiefly in being more energetic; a slovenly *d* slides into *l*. Thus the Greek name, Odysseus, became, in the mouth of the Romans, Ulysses; they said *odor* (a smell), but *oleo* (I smell); and, instead of *impedimentum*, *dedicare*, we sometimes find *impelumentum*, *delicare*. These and other instances would warrant us to conclude that *lacri-ma* was a corruption of *dacri-ma* (corresponding to Gr. *dakru*), even if we had not the express statement of Festus that *dacrima* was the older form. After this there is no difficulty in recognizing *dacri*, or *dakru*, as identical with Gothic *tagr*, Eng. *tear*.

In order to give a rational account of the phonetic changes now exemplified, the nature of articulate sounds, and of the organs that produce them, must be carefully investigated. The most valuable contributions, in English, to this important preliminary branch of the study (called *Phonetics*), are those of Mr. Alex. J. Ellis, and of Mr. Melville Bell, in his book entitled *Visible Speech*. See PHONETIC WRITING and VISIBLE SPEECH. A résumé of the subject, with diagrams of the organs of voice in the position of pronouncing the different articulations, is given in the second series of Max Müller's *Lectures on the Science of Language*.

The transformations that words exhibit, as they are traced down the stream of history, are of the nature of phonetic decay, and are due to a natural tendency to economize muscular energy by pronouncing two syllables in one. The dropping of inflections, the shortening of words by internal elision and otherwise (Fr. *père*, from Lat. *pater*; Eng. *fair*, from A. S. *fæger*; *stranger*, from old Fr. *estrangier*, Lat. *extraneus*), are all owing to the action of this force, and the uniformities observable among such changes, can be explained on physiological principles.

Dialectic diversification is not so easily accounted for; it is difficult to say why sister nations—as in the case of the Aryan family, or of the nations speaking Romanic tongues—should have given such different forms to the same stock of primitive roots; why, e. g., Gr. *pente* (Æol. *pempe*), *pepo*, should be in Lat. *quinque*, *cogno*. Max Müller thinks it necessary to go back to a time when many of the articulations were not yet sharply defined; and he appeals, in illustration to the confusion children make between such sounds as *tat* and *cat*; and, what is still more in point, to the analogy presented by languages like the Polynesian. In the language of the Sandwich Islands, the two consonants, *k* and *t*, run into one another, and it seems impossible for a foreigner to say whether what he hears is a guttural or a dental. The same word is written by Protestant missionaries with *k*, by French with *t*. It takes months of patient labor to teach a Hawaiian youth the difference between *k* and *t*, *g* and *d*, *l* and *r*. . . . If colonies started to-morrow from the Hawaiian Islands, the same which took place thousands of years ago, when the Hindus, the Greeks, and Romans left their common home (see ARYAN), would take place again. One colony would elaborate the indistinct, half-guttural, half-dental contact into a pure guttural; another, into a pure dental; a third, into a labial. Much light is thrown on this question by those phonetic peculiarities—those deficiencies and predilections of articulation which characterize whole tribes and nations, as they often do individuals. They may have originated, perhaps, in the idiosyncrasies of individual ancestors (a lisping patriarch might produce a tribe of lispers, without their inheriting the physical defect which caused the lisp in him), or in a common habit of the organs of speech produced by external circumstances; but once established, they are very persistent and influential.

The Mohawks, and several other American tribes, have no *p*, *b*, *m*, *f*, *v*, or *w*; they never articulate with their lips. In Chinese, there is no *d*; *r* is also wanting; and as the habit of the language requires a vowel after every consonant, the nearest approach they can make to the sound of *Christ* is *Ki-li-se-tu*. An analogous habit of articulation transforms the English word *gold* in the mouth of a Kafir into *i-go-li-de*. On this principle can be explained the Fr. *espérer*, from Lat. *sperare*; *établir* or *établi*, from *stabilire*; *école* (*escole*), from *schola*, &c. In the Celtic tongue, an initial *s* with a consonant after it was an unwonted combination; when it would have occurred, a vowel was always prefixed; and, on adopting the Latin language, the Celtic peoples carried their old habit of pronunciation with them. The effects upon a language of thus coming in contact with another, are important elements in its history. See ENGLISH LANGUAGE and LITERATURE.

The positive part of the science of language having pushed inquiry back until it arrives at monosyllabic roots that admit of no

further analysis, there stops, as at the legitimate boundary of its province. It assumes the existence of a certain store of crude or primary matter, and merely concerns itself with how out of this matter the structure as we know it, has been built or has grown up. But a question yet remains, which, although it can never receive but a conjectural answer, has a wonderful fascination for the speculative mind, and was, in fact, the question with which all inquiries into language began; the question, namely: How did language take a beginning at all? how came this primitive material of language, these significant roots, into existence? The answer may be thus conceived: To speak is a necessity of man's rational and emotional nature; he speaks because he thinks and feels. When the mind receives an impression or intuition, by an instinctive impulse of the nature of reflex action, some outward expression—a gesture or vocal sound—breaks forth, which by association, becomes a sign or symbol, to the individual and to his associates, of the impression or idea that gave it birth.

Associated at first with individual impressions and objects, these sounds, by the process of abstraction, which is pre-eminently a human faculty, would gradually come to represent more generalized impressions—would become words, as distinguished from mere animal sounds. The necessity of words to think in is much insisted on by speculators on this subject, as being the motive-power in the generation of language; and no doubt it is true that, without language, thought could advance but little, if at all, beyond what is manifested by the brutes. But when they argue as if this necessity of having his ideas objectively depicted, in order to exercise his own reason, would impel an individual man to construct a language for his own use, they make the unwarranted assumption that, under any circumstances, even though he grew up from infancy in solitude, the thinking powers of a human being must necessarily develop themselves. The necessarily few facts that bear on the case look the other way. Kaspar Hauser (q. v.), instead of elaborating a system of symbols of thought for himself, had forgotten what he had once possessed; his faculties of thought and of speech seem to have been simultaneously arrested. Observation seems to favor the opinion, that man in solitude—if he could exist in solitude—would be as mute as the lower animals. The social nature of man helped to give birth to the germs of speech, no less than to his rational nature; an instinctive desire to give a sensible sign of his impressions to his fellows, was perhaps the primary impulse; the aid thus given to his own thinking powers, a secondary result. Be this as it may, it seems reasonable to assume, as it has been well put by Steinthal, that 'at the origin of humanity, the soul and the body were in such mutual dependence, that all the emotions of the soul had their echo in the body, principally in the organs of respiration and the voice. This sympathy of soul and body, still found in the infant and the savage, was intimate and fruitful in the primitive man; each intuition woke in him an accent or a sound.'—Farrar, *Origin of Lang.*

Were these sounds, then, guided by chance or caprice? or if not, what determined particular articulations to be associated with particular objects or ideas? Any mystic innate correspondence between sounds and things, is out of the question; but what more reasonable than to suppose that the natural sounds emitted by so many things, animate and inanimate, should suggest the character of the articulations which the ideas of the things called forth—not so as to produce exact imitations, which it is not of the nature of articulate sounds to be, but such resemblances as would suffice for association. See ONOMATOPEIA. In the case of ideas unconnected with any natural sound, names would readily be suggested in many cases by analogies, real or fancied, with things that were attended by sounds. We can see, again, a physiological fitness in the articulation *sta*, to stand, with the idea of stability; with the attitude, the organs involuntarily assume the position with which this syllable is emitted. Similar instances might be multiplied. We are not to suppose that the same thing would suggest the same sound to all, or even to the same individual at all times. The language-making faculty in the flush of its spring would throw out a multitude of names for the same thing (synonyms), as well as apply the same name to many different things (homonyms); but by a process of natural elimination, those only would survive that were felt best to answer the purposes of speech. The abstracting faculty would also soon dissociate them from the concrete individual objects that first suggested them, and convert them into symbols of the prominent attributes of whole classes. It is these generalized names, syllables significant of such general simple notions as seeing, moving, running, shining, striking, cutting, or being sharp, that, by a kind of inverse process, became the roots of language as it now exists.

A syllable expressive of a single prominent attribute forms the foundation of the names of a whole class of objects, the specific differences being marked by other significant syllables joined on to it. See ROOTS. In some such way, by the unconscious working of man's intellectual nature, we may conceive language to have grown out of the exclamatory or interjectional stage into the

rational structure that we now admire. This theory of the origin of roots, together with the constant operation of phonetic change, accounts for the absence of all traces of onomatopoeia in the great bulk of the words of a language, and seems to meet the objections of Max Müller and other philologists to the onomatopoeic theory.

With regard to these primary or radical words it is only necessary to observe here that they are all significant of sensible or physical ideas, and expressions for immaterial conceptions are derived from them by metaphor. How, from a comparatively few roots of this kind, the vocabulary of the richest language may grow, is further illustrated in the article *Root*.

Another speculative question regards the length of time that language must have taken to advance from the rudimentary stage to the state in which it is found in the earliest records. Bunsen assigns 20,000 years as the lowest limit; but it is evident that the same uncertainty must always rest on this question as on the corresponding one in geology.

Separate points of philology will be found treated under a variety of heads. See—besides the articles already referred to—*ALPHABET*; the several letters, *A, B, &c.*; *GENITIVE*; *NOUN*; *ADVERB*; *PRONOUN*; *DIALECT*; *PERSIAN LANGUAGE AND LITERATURE*; *SEMITIC LANGUAGES*; &c.

The literature of the new science of language is already rich; but much of it is scattered through the transactions of societies and periodicals. Of separate works of a comprehensive kind, in addition to those already named, we may mention, in German, Schleicher, *Die Sprachen Europas* (Bonn, 1850), and *Vergleichende Grammatik der Indo-Ger. Sprachen* (2 vols. Weimar, 1861); J. Grimm, *Ueber den Ursprung der Sprache* (Ber. 1852); Diez, *Etymol. Wörterbuch der Romanischen Sprachen* (2d ed. Bonn, 1861), and *Vergleichende Grammatik der Romanischen Sprachen* (3 vols. Bonn, 1836—1842); translations of both works into English have been published by Williams and Norgate (1864). Heyse, *System der Sprachwissenschaft* (Ber. 1856); Steinthal, *Die Classification der Sprachen* (Ber. 1856); and *Der Ursprung der Sprache* (Ber. 1851). In French, Renan, *Histoire Générale et Système comparé des Langues Semitiques* (3d ed. Paris, 1863); and *De l'Origine du Langage* (3d ed. Paris, 1863); Pictet, *Les Origines Indo-Européennes* (Paris, 1859).

English scholars were late in entering this field of research. Horne Tooke's (q. v.) *Diversions of Purley*, though a work of genius, and though it has been the means of first awakening in many an interest in the nature of language, was written without sufficient acquaintance with the kindred tongues, and before the true key to the inquiry had been obtained, and therefore few of the results can now be accepted. Among the first important contributions were Richard's *Eastern Origin of the Celtic Nations* (Oxf. 1831), and the contributions of the Rev. Richard Garnett to the *Quarterly Review* in 1835—1848. Mr. Garnett's essays in the *Quarterly*, and his subsequent papers printed in the proceedings of the London Philological Society (in the formation of which, in 1842, he took an active part), have been reprinted under the title of *Philological Essays* (Williams and Norgate, 1859), and are models of linguistic research. The philological articles of the *Penny Cyclopædia* also contributed to popularize the study in England.

Of substantive works, the most important, though bearing more directly on the Greek and Latin tongues, are *The New Cratylus* (1839, 3d ed. 1859), and the *Varronianus* (1844) of J. W. Donaldson (q. v.). Winning's *Manual of Comparative Philology* (1838) had previously given a popular sketch of the affinities of the Aryan languages. Latham's *Elements of Comparative Philology* (1862) gives an elaborate classification of the languages of the world, with specimens; only a small part of the work is given to the general principles of the science. Farrar, *On the Origin of Language* (1860), chiefly deals with the speculative part of the subject; in his *Chapters on Language* (new ed. 1873), he defends his original positions; his *Families of Speech* (new ed. 1873) deals with classification. The writings of Max Müller (*Comparative Mythology* in the *Oxford Essays*, 1856; *Lectures on the Science of Language*, 1861; second series, 1864; new ed. of both, 1871) went far to make the study of this science take root in Britain. The principles of linguistic science are set forth in Whitney's *Language and the Study of Language* (1868), and *The Life and Growth of Language* (1875). Other recent works are: Key's *Origin and Development of Language* (1874); and Sayce's *Principles of Comparative Philology*.

On the principles of classification above sketched, the chief languages of the earth may be thus arranged:

I. *Monosyllabic or Isolating*.—1. Chinese, the typical language of this order. 2. Tibetan, which shows some beginnings of grammatical forms. 3. The languages of the Eastern Peninsula—Siamese, Anamese, Burman, Japanese and the language of Corea are doubtful.

II. *Agglutinate*.—1. The most important division of this order is the Turanian family, comprising 'all languages spoken in Asia and Europe (including Oceania), and not included under the Aryan and Semitic families, with the exception of Chinese and its

cognate dialects. For the subdivisions of this family, see **TURANIAN LANGUAGES**. 2. *African Languages*.—Some of the languages of Africa are allied to the Semitic family, and were introduced by immigration, such as the dialect of Tigré in Abyssinia (see **ETHIOPIA**), and the Arabic dialects spoken by the Mohammedan population of the coasts, and which have even penetrated deep into the interior. How far the Berber dialects are of Semitic character, is a disputed question; and the same is the case with the language of the Gallas in Abyssinia. Little has as yet been done in investigating and classifying the native Agglutinate languages of Africa, which have been designated by the common name of Hamitic. The ancient Egyptian, from which the modern Coptic is derived, would seem never to have got beyond the isolating stage (see **HIEROGLYPHICS**). Some of the languages adjoining Egypt are thought to be allied to the Coptic. The negro languages, properly so called, of the Sudan, and of the west coast from the Senegal to the Niger, are exceedingly numerous and widely diverse. The languages to the south of the equator are

markedly different from those to the north. They fall, according to some, into two great families, the Congo family on the west, and the Kafir family on the east. The Hottentot language is distinct from both. A valuable contribution has recently been made to the study of part of the field by Bleek's *Comparative Grammar of the South African Languages* (1862). 3. *The Languages of the American Indians*.—The native languages of the New World are numbered by many hundreds, all differing totally in their vocabulary, but still agreeing in the peculiar grammatical structure which has given the name of Incorporative (see above). Their area is fast contracting, and they seem destined to disappear.

III. *Inflectional*.—This order consists of two families so distinct in their grammatical framework that it is impossible to imagine a language of the one family derived from one of the other. It is the peoples speaking these languages that have been the leaders of civilization within the historic period. The subdivisions of these families will be best understood from the accompanying tables, taken from Max Müller's Lectures, First Series.

PHILOMELA, the name of a personage in Greek legend, who was changed according to one account into a swallow, to another into a nightingale. Modern poets are (or rather were, for it was chiefly an 18th c. fashion) fond of calling the nightingale by its classic name.

PHILOPÆ MEN, the most illustrious patriot and general who figures in the later history of Greece, belonged to one of the best families of Arcadia, and was born at Megalopolis about 252 B.C. At an early age he lost his father, and was brought up by a wealthy citizen, named Cleander, who took care that he should receive an excellent education. His earliest experiences of war were confined to the border raids of the Arcadians into Laconia; but in 222 B.C., he was one of the defenders of Megalopolis against Cleomenes, king of Sparta. Next year, when the Macedonian king Antigonus marched to the assistance of the Achæans, P. joined him at the head of 1000 horse, and contributed materially to the terrible defeat which the Spartan king received at Sellasia. As tranquility was now for a short time restored to Greece, P. went abroad to perfect himself in the art of war, and served in Crete with such distinction, that on his return to the Peloponnese, in 210, he was appointed general of the Achæan horse, and at once proceeded to discipline his men in a vigorous and masterly style. In the expedition against Elis (209) he slew the Elean leader, Demophantus with his own hand. In 208 he was raised to the highest military dignity then possible in Greece, being elected *strategus* or commander-in-chief of the Achæan League, and in this capacity signalized himself by the great improvements which he effected in the drill, discipline, and armor of the Achæan soldiery. It seemed as if the ancient heroism of the land were reviving.

The battle of Mantinea, which took place in the course of the same year, and in which the Spartans were again utterly routed—their general and king, Machanidas, falling by the sword of P. himself—raised him to the pinnacle of fame, and at the Nemean festival which followed he was proclaimed liberator of Greece. His exalted honors did not in the slightest degree disturb the integrity of his character. So great was his influence over his quarrelsome countrymen, that the Macedonian monarch, Philip, began to fear that Greece would regain its independence, and tried to have him secretly assassinated; but the infamous treachery was discovered in time, and its only effect was to endear P. still more to the Achæans. Another of his determined enemies was Nabis, successor of Machanidas in the 'tyranny' of Sparta, but in 201 he inflicted on the latter a severe defeat at Skotetas on the borders of Laconia. During the next few years he was absent in Crete, partly, it would seem, for political reasons, but returned to the Peloponnese in 194 to find matters in a serious condition. A new and dreaded power—the Romans—had appeared, and overthrown both Philip and Nabis, and P. foreboded future mischief to all Greece from these ambitious warriors. On the departure of the consul Flamininus, Nabis recommenced hostilities against the Achæans; P. was once more appointed *strategus* (192); and in a pitched battle nearly annihilated the troops of Nabis, who himself was shortly afterwards killed by the Ætolians. He now exerted all his power to heal the divisions among the Achæans, and to prevent them from affording the Romans a pretext for taking away their independence. In 188, he took a fierce revenge on Sparta for having put a number of his friends to death, and was in consequence strongly censured by the Roman senate, and by Q. Cæcilius Metellus, who was sent out as a commissioner to Greece in 185.

Two years later P. (now an old man of 70) was elected *strategus* for the eighth time. When lying ill of a fever at Argos, news was brought to him that the Messenians had broken their connection with the league; P. instantly rose from his sick bed, hastened at the head of some cavalry to quell the revolt, but was overpowered by numbers, and fell into the hands of Deinocrates, the leader of the Messenians, who two nights after sent him a cup of poison, which P. drank off and died. The remains of the hero were brought in solemn procession to his native city—the historian Polybius carrying the urn—and statues were erected to his memory by his grateful and repentant countrymen.

PHILOSOPHY. This word meant originally the 'love of knowledge,' and indicated, therefore, a special taste, appetite, or desire, of which the subject-matter was knowledge. At first, man's pursuit of knowledge was subservient to the immediate uses of life; but, in the course of time, an interest was taken in knowing the order of the world, independent of its application to the common utilities. We find that this stage had been reached in Greece especially, about five or six centuries before Christ; at which time the name 'philosophy' took its rise, being attributed to Pythagoras.

The world has had a variety of acceptations, although all pervaded by the one idea of employing the human understanding in the search for increasing knowledge and certainty. It always implies this effort in a distinguished degree, such as only a few

persons in any age have ever been able to sustain. The pursuit of knowledge had to become an end in itself, for the mere improvement of practice would not at first have been a sufficient motive for men to undergo the labors of scientific inquiry. Indeed, this improvement was not at all apparent as a consequence of the earliest efforts of speculation. As one celebrated example, the investigation of the properties of the sections of the cone—the ellipse, parabola, and hyperbola—was without any practical use for nearly two thousand years.

As may be readily supposed, the precise aim of philosophy, the statement of what constitutes its end, has varied with the advancement of its study. In modern times the pursuit of truth has taken a well-defined form, expressed by the name Science (q. v.). But, in the ancient world, this operation was a mixture of speculation, practice, and sentiment—of legitimate inquiry with aspirations after the unattainable; and hence the word 'philosophy,' in its modern employment, often refers to the subjects that have not as yet adopted the strict scientific form. On this view, science is the goal and the grave of philosophy. (See Lewes's *Biographical History of Philosophy*.) It is chiefly with reference to morals, metaphysics, and the human mind generally, that the term is still retained.

The characters that distinguish the highest form of truth are Generality and Certainty or precision; and in proportion as a subject has advanced in these respects, it might be said to have become philosophical, but we now prefer to use the word scientific. The theoretical foundations of a practical subject, as grammar, are sometimes pretentiously called the philosophy of it. So any department of nature or humanity, where explanations by general laws are furnished, is styled 'philosophical'; thus, we have the philosophy of zoology or of history, and a 'philosophical' naturalist or historian.

Again, after definite branches of knowledge have taken a scientific shape, and have been reckoned as distinct 'sciences' mathematics, &c., the general principles and views that are supposed to run through the whole, are sometimes called 'philosophy.' This was one of the meanings of the word in Plato. The great work of Auguste Comte bases its title (*Cours de Philosophie Positive*) upon this consideration.

Professor Ferrier remarks that philosophy is not truth, but 'reasoned truth'; that is, it must be truth presented under the forms and processes that evolve and establish the highest or scientific knowledge. This is merely another mode of stating that philosophy implies a special procedure for attaining truth, the ordinary unregulated operations of the understanding being insufficient.

Among the oldest problems of philosophy, we are to reckon the attempt to generalize the universe, or to resolve all nature into some great unity, or common substance or principle. Thales considered Water the primordial and fundamental principle. Anaximander adopted as the foundation of the universe something called by him the Infinite or Indeterminate, out of which the various definite substances, air, fire, water, &c., were generated, and to which they were again resolved. Anaximenes assumed Air as the primordial substance, which, by rarefaction, produced fire and ether, and by condensation, water, earth, and stone. These three philosophers all belonged to the Ionic colony of Miletus. Pythagoras was an emigrant from Ionia to Italy; he gave Number as the essence and foundation of all existing things: the different numbers being representative of different natural properties and powers; thus, *five* stood for color, *six* for life, &c. Xenophanes of Kolophon attacked the popular polytheism, and propounded one great indivisible agency comprehending and identified with the universe, which he would not designate as finite or infinite, in motion or at rest. Parmenides of Elea distinguished between self-existent being, Ens, or the absolute, characterized by extension and duration, and phenomenal nature, the region of inferior certainty, or mere opinion. This was the first sketch of what has since been called Ontology, or the science of the *noumenon*, or absolute being. Heraclitus of Ephesus maintained an absolute of a totally different character—a principle of incessant Change, the negation of all substance and stability, a power of perpetual destruction and renovation.

Empedocles took his stand upon the Four Elements out of which all things were constituted by the action of the opposing principles of love, and enmity or discord—a poetical representation of attraction and repulsion. Anaxagoras also treated the world as made up of elements, but indefinite in number. By the attraction of each for its own kind, the primitive chaos was separated, but, excepting 'mind,' no element ever was perfectly pure, the character of each substance being determined by the predominance of the proper element. These elements were called the 'homœomeries.' Diogenes of Apollonia, the last of the series called Ionic philosophers, adopted in a modified form the tenet of Anaximenes, that Air was the primordial element. The celebrated Atomic theory originated with Leukippus, but is commonly identified with his pupil Democritus of Abdera. The elements of Anax-

agoras were acted on by mind, but with Democritus their activity was inherent in themselves from the beginning.

The grand problem of External Perception (see PERCEPTION) was agitated at an early period, and has been always reckoned a leading question of philosophy. The first attempt at a solution was an application by Democritus of his atomic hypothesis. He supposed that all things were constantly throwing off images of themselves, which enter the soul through the pores of the organs of sense. He was aware that this left us in a state of uncertainty, as to whether the images corresponded to the otherwise unknown originals.

The many difficulties and uncertainties incident to the search for knowledge, could not but be felt by inquirers generally. There was one sect in particular, more especially impressed by this circumstance, and hence called Sceptics or Doubters. They were represented in antiquity by Pyrrho. They dwelt on the absence of any sure criterion of truth, and pointed out that what was considered most certain was not free from objections, or counter-arguments.

Philosophical speculation began to take definite shape in the age of Plato and Aristotle, the age of the beginnings of many of the sciences. More especially at this time do we find the distinct enunciation of the Philosophy of Human Life, otherwise called Moral and Ethical Philosophy. The questions concerning the end of life, the pursuit of happiness, and men's duties in various relationships, had been answered by a sort of rule-of-thumb experience, rather than by deep reflections or farseeing combinations. The distinctions of virtue and vice were determined by political society, and connected more or less with religion. There were tests and maxims of conduct, for the most part merely prudential. The first approach to a moralizing strain is found in the poems of Hesiod. He combines a gloomy view of life with much practical wisdom, enjoining justice, energy, temperance, and simplicity of living. The 'Seven Wise Men,' who belonged to the 6th c. B.C., followed in the same course, and uttered a variety of sayings or short maxims, of which the most ordinary subjects were 'the uncertainty of human things, the brevity of life, the unhappiness of the poor, the blessing of friendship, the sanctity of an oath, the force of necessity,' &c., together with the simple rules of prudence.

The most celebrated saying of this age was the Delphian inscription (of uncertain authorship), 'Know thyself.' The teaching of the Sophists made another stage in the history of moral philosophy. They opened up discussions on virtue, on justice, on the laws, and on happiness; and framed hortatory addresses with a view to moral culture. Socrates then came forward, and instituted a severe logical analysis of the meaning of ethical terms, asking 'What is piety? What is impiety? What is the noble? What the base? What is just? What is temperance? What is madness? What is a state? What constitutes the character of a citizen? What is rule over man? What makes one able to rule?' The rigid search after strict definitions of these terms may be said to constitute a philosophical method in ethics, and hence Socrates is called the first moral philosopher. He gave the impulse to Plato, his successor, who in his turn acted upon Aristotle, and also to the opposing sects of the Cynics and the Cyrenaics—the one affecting a hard and ascetic life, and a proud superiority of the individual will to all outward conventions and customs; the other avowing pleasure as the chief good, sitting loose to the irksome duties of the citizen, and in despair of attaining happiness, sliding into apathy. The Stoics and the Epicureans afforded a similar contrast, although differently expressed. The Stoic ideal was a being in whom the natural impulses and desires should be absolutely subjected to highly abstract views of the universe: the Epicurean ideal was a being moving harmoniously according to natural impulses—in short, following nature up to the limits of prudence.

The last phase of ancient philosophy is represented by Neo-Platonism (q. v.), or the Alexandrian school. In the middle ages, speculative philosophy took the form called Scholasticism (q. v.). At the revival of learning, Descartes and Bacon led in opposite directions, the one representing what is called *a priori* philosophizing; the other, *Induction* (q. v.). From this time, 'philosophy' comes to mean more exclusively the inquiries connected with the mind, as exemplified in the writings of Hobbes, Locke, Leibnitz, Berkeley, Hume, Reid, Kant, &c. The qualified phrase, Natural Philosophy (in the English sense), was applied to a special department of the outer world, as Moral Philosophy was used in connection with mind and the discussion of moral duties. The chief points in the history of modern philosophy will be found under the heads of GERMAN PHILOSOPHY, ECLECTICISM, COMMON SENSE, PERCEPTION, METAPHYSICS, ETHICS; and in the notices of BERKELEY, LOCKE, HUME, REID, KANT, HEGEL, FICHTE, COUSIN, HAMILTON, &c.

PHILOSTRATUS, the Elder, of Lemnos, a famous Greek sophist and rhetorician, was born probably about 170—180 A.D.,

studied under Proclus at Athens, and finally established himself at Rome, where he became a member of the brilliant and learned circle that gathered round the 'philosophic' Julia Domna, wife of Severus. He was alive, according to Suidas, in the time of the Emperor Philip (244—249). He is the author of a number of works still extant, and not without value on account of their matter, although the style and arrangement are faulty. Among them are a life of Apollonius (q. v.) of Tyana, a description of a collection of paintings at Naples under the title of *Imagines*, biographies of a number of sophists, *Heroica*, Letters, &c. There are complete editions of his works by Morel (Paris, 1608); Olearius (Leip. 1709); and Kayser (Zur. 1844, *et seq.*), of which the last is by far the most correct and critical.—PHILOSTRATUS the Younger, called Philostratus the Lemnian, also a teacher of elocution, was an intimate friend, perhaps a relative of the former, but nothing is known with certainty regarding him.

PHILT'ER, PHILTRE (Gr. *philt'ron*, love-charm, love-potion). A superstitious belief in the efficacy of certain artificial means of inspiring and securing love, seems to have been generally prevalent from very early times; and among the Greeks and Romans (among the latter in the later days of the republic, and under the emperors), love-charms, and especially love-potions, were in continual use. It is not certainly known of what these love-potions were composed—nor can we rely entirely on the details given us on this subject by classic writers, and their commentators in later time—but there is no doubt that certain poisonous or deleterious herbs and drugs were among their chief ingredients, to which other substances, animal as well as vegetable, are said to have been added, coupled with the employment of magic rites. Thessaly had the credit of producing the most potent herbs, and her people were notorious as the most skilful practisers of magic arts, whence the well-known 'Thessala philt'ra' of Juvenal (vi. 610). These potions were violent and dangerous in operation, and their use resulted often in the weakening of the mental powers, madness, and death, instead of the purpose for which they were intended. Lucretius is said to have been driven mad by a love-potion, and to have died by his own hand in consequence—though the story does not perhaps rest on sufficient authority; and the madness of the Emperor Caligula was attributed by some persons to love-potions given him by his wife Cæsonia—by which also she is said to have preserved his attachment till the end of his life. In the corrupt and licentious days of the Roman empire, the manufacture of love-charms of all kinds seems to have been carried on as a regular trade; the purchasers, if not the makers of them, being chiefly women. The use of philters seems to have been not unknown during the middle ages; and in the East, the nurse of superstition of all kinds, belief in the power of love-potions lingers probably down to the present day.

PHLEBE'NTERISM is a term invented by De Quatrefages to designate an anatomical arrangement, existing, as he supposed, in certain of the nudibranchiate molluscs, and characterized by ramified prolongations of the digestive tube, in virtue of which the digestive apparatus, to a certain extent, supplies the place of a complete circulatory apparatus, and aids in the process of respiration. The researches of Alder and Hancock, and other zoologists, seem, however, to show that in these animals the circulation is as complete as in the gasteropodous molluscs generally, and that these ramified prolongations are of the nature of a rudimentary liver. For further information on this subject, the reader is referred to De Quatrefages's *Rambles of a Naturalist*, vol. i. pp. 348—353.

PHLEBI'TIS, or INFLAMMATION OF THE VEINS (Gr. *phlebs*, a vein), although seldom an original or *idiopathic* disease, is a frequent sequence of wounds, in which case it is termed *traumatic* phlebitis (from the Greek *trauma*, a wound), and is not uncommon after delivery. The disease is indicated by great tenderness and pain along the course of the affected vessel, which feels like a hard knotted cord, and rolls under the fingers. The hardness is, however, sometimes obscured by the swelling of the limb beyond and about the seat of the disorder, partly in consequence of the effusion of serum caused by the obstruction to the return of the venous blood (which thus gives rise to a local dropsy), and partly in consequence of the propagation of the inflammation to the surrounding tissues. The inner surface of the inflamed vessel is supposed to throw out fibrinous fluid, which coagulates in layers, and finally closes the tube. If the vessel is small, the consequences of its obstruction may be of little importance, but when a large vein is affected, the consequences are always dangerous, and may be fatal.

There are two modes of recovery: solution of the coagulated fibrine may take place, and the vessel may again become pervious; or, as is more commonly the case, the obstruction may continue, but a collateral venous circulation may be established, and the circulation thus carried on through a circuitous route. With the return of the circulation—in whichever of these two ways it is ac-

complished—the swelling subsides, and the patient gradually recovers. If, however, the disease advances, suppuration takes place within the coagulum, and one of two things happens; either abscesses are formed along the vein, or the pus gets into the current of blood and contaminates the circulation, giving rise to the perilous disease known as *Pyæmia* (q. v.). Either condition is dangerous; the latter pre-eminently so.

Phlebitis generally originates in some local injury of a vein, and the inflammation, when once established, is readily propagated along the course of the vessel. Sometimes very slight injuries give rise to it. It occasionally occurs after venesection, especially with a dull lancet, or one soiled by contact with diseased matter. Women are peculiarly liable to this disease after delivery, as the veins of the womb are apt to become inflamed, and to communicate the inflammation to the venous trunks connected with them. See **PHLEGMASIA**.

There is considerable difference of opinion as to the treatment to be pursued; some high authorities (Dr. Wood, for example) recommending 'the very free use of leeches along the affected vein,' and that they 'should be repeated over and over again if the symptoms of inflammation should persevere,' the subsequent application of cold lotions, and the internal use of mercury 'pushed to a moderate salivation,' while others question the utility of such treatment, and recommend 'rest, warm fomentations, and poultices, early incision of abscesses, evacuation of bile and fæces by one or two doses of calomel, opium to relieve pain and insure quiet of mind and body, and wine, especially if there has been great loss of blood.'—Druitt's *Surgeon's Vade Mecum*, 8th ed., p. 326. The latter is in most cases the preferable mode of treatment.

During convalescence, the patient must be satisfied if the swelling goes down slowly. Time is required for the enlargement of the veins by which the collateral circulation is to be carried on; and active counter-irritation, such as the application of ointments of iodine or mercury, if employed incautiously, frequently does harm by increasing the inflammation. With care, however, they are useful appliances; and if, after giving them a fair trial, much swelling should remain, the practitioner must have recourse to carefully regulated bandaging, and the use of diuretics.

PHLEBOLITES (Gr. *phleps*, a vein, and *lithos*, a stone) are calcareous concretions formed by the degeneration of coagulations in veins, or occasionally originating in the coats of the vessel. They are seldom detected till after death, although cases are on record in which, occurring in subcutaneous veins, they have given rise to external tumors of considerable size.

PHLEBOTOMY. See **BLEEDING**.

PHLEGETHON, i. e., the Flaming, a river of the infernal regions, whose waves rolled torrents of fire. Nothing would grow on its scorched and desolate shores. After a course contrary to the Cocytus (q. v.), it discharged itself, like the latter stream, into the Lake of Acheron.

PHLEGMA'SIA A' LBA DO'LENS, or **MILK-LEG**, is a disease which is most common in women after parturition, especially if they have lost much blood, but sometimes occurs in unmarried women, and occasionally in males. It usually commences about a week or ten days after delivery with a feeling of pain in the loins or lower part of the abdomen, whence it extends to the groin and down the thigh and leg. The pain soon becomes very severe, and principally follows the course of the internal cutaneous and crural nerve of the thigh and of the posterior tibial in the leg. The limb soon begins to swell, and in the course of a couple of days, is sometimes twice its ordinary size, and as the swelling develops itself, the acuteness of the pain considerably diminishes. The limb is partly flexed, and lies motionless; any movement aggravates the pain. The swelling extends uniformly over the limb, which is pale and shining, and hot and firm to the touch, seldom pitting on pressure. The femoral vein may usually be felt like a hard chord, and this symptom, taken with the swelling, clearly indicates that this affection is essentially *crural phlebitis*. The uniformity of the cord is interrupted by nodules, arising either from inflamed cellular tissue, or from clots within the vein. Both legs are seldom attacked at the same time, and the left thigh is the most common seat of the disease.

This affection usually terminates favorably, the acute symptoms disappearing in about ten days or a fortnight. The swelling, however, often continues for a long time, and sometimes lasts for life. Very different opinions have been held regarding the nature of this disease. At one time it was considered as the result of metastatic secretion of milk (or, in other words, as due to the milk leaving the breast, and settling in the thigh, and hence the term *milk-leg*). There is now no doubt that the disease is inflammation originating in the veins of the womb, and extending to those of the lower extremity. The treatment is the same as for Phlebitis (q. v.) generally. Warm poppy fomentations, or bran poultices sprinkled with laudanum, may be applied externally at the beginning of the attack, after which flannel saturated with a lini-

ment, composed of one part of laudanum to two parts of soap liniment, may be applied round the limb in the form of a bandage, applied not so tightly as to occasion pain. If necessary, the bowels must be gently opened with castor oil, and opium given to allay pain and induce sleep.

PHLE'UM. See **TIMOTHY GRASS**.

PHLOGI'STON (Gr. *combustible*) was the term employed by Stahl, professor at Halle, in his *Zymotechnia Fundamentalis*, 1697, to designate a hypothetical element which, by combining with a body, rendered it combustible, and which occasioned combustion by its disengagement, there being left, after its evolution, either an acid or an earth. In the above-named work, he maintains that the processes of obtaining sulphur from sulphuric acid, and of procuring the metals from their earths or *calces*, are analogous, and consist alike in the addition of his phlogiston. Thus, sulphur, according to the phlogistic theory—which held undivided sway, in chemistry until the time of Lavoisier, who substituted for it the theory of oxygenation (1775–1781), and was maintained by a few chemists, especially Priestley, till the beginning of the present century—was composed of sulphuric acid and phlogiston; lead, of the *calx* of lead and phlogiston; &c. In consequence of the general adoption of the phlogistic theory, when Priestley, in 1774, discovered oxygen, and when Scheele, a little later, discovered chlorine, the names these chemists gave to their discoveries were *dephlogisticated air* and *dephlogisticated marine acid*. According to modern views, mainly based on Lavoisier's experiments, the addition of oxygen takes place in the formation of acids and of earths, instead of the subtraction of phlogiston. The question whether the process was, in fact, one of addition or subtraction, was finally decided by the balance, an instrument to which chemistry owes most of its marvelous progress during the last three-quarters of a century.

PHLOX, a genus of plants of the natural order *Polemoniaceæ*, distinguished by a prismatic calyx, salver-shaped corolla, and unequal filaments. The species are pretty numerous, mostly perennial plants with simple leaves, and mostly natives of North America. A number of species are common in our flower-gardens. This has of late become a favorite genus with florists, and many very fine varieties have been produced.

PHO'BEROS, a genus of trees of the natural order *Flacourtiaceæ* or *Bixaceæ*, of which one species, *P. Mundtii*, the *Klipdoorn* of the Dutch colonists of South Africa, although only 20–30 feet high, attains a diameter of three feet or more, and is very useful for the purposes of wagon-makers and house-carpenters, the wood being hard and fine-grained; another South African species, *P. Ecklonii*, the *Roodpeer* of the colonists, has a hard, heavy, and fine-grained wood, used by cabinet-makers, mill-wrights, &c.

PHOCÆ'NA. See **PORPOISE**.

PHO'CAS, emperor of Constantinople (602–610), was a Cappadocian by birth, and was for some time groom to Priscus, one of the celebrated generals of the Emperor Mauricius (q. v.). His brutal courage gained him a great reputation among the soldiers, and though only a centurion at the time of the revolt against Mauricius, he was elevated to the throne by the soldiers. To secure himself, he caused Mauricius to be murdered, along with his five sons and his principal adherents; and then, by a treaty disgraceful to the empire, got rid of the Avars. But his troubles were just commencing, for Khusrû II. (q. v.), Shah of Persia, hearing of the death of his friend and benefactor, Mauricius, an event which freed him from the obligation of amity with the Eastern Empire, took up arms to revenge his friend's murder, and to recover for Persia all the territories previously under her sway. The war was fiercely carried on for 24 years, during the first 18 of which the Persian army were uniformly successful, and the Byzantines were almost completely driven out of Asia. See **KHUSRU II.** and **HERACLIUS**.

P. remained in the capital, to overawe his turbulent subjects, conscious of his unfitness to command the army; and abandoned himself to his animal appetites, tyrannizing over the people without the least regard to justice, and putting to death whomsoever he thought dangerous, among others, Narses, the celebrated general in the former Persian war. Constantina, the widow of Mauricius, excited against the tyrant two formidable insurrections, the latter in 607, but both were speedily quelled; and the ex-empress, with her daughters, were beheaded on the same spot where her husband and sons had been slain. Her principal adherents, some of whom were among the highest officers of state, suffered death under the most horrible tortures. These cruelties, and the successes of the Persians, had well-nigh ruined P.'s power and influence. But he gave the *coup de grâce* to it himself by insulting his favorite and son-in-law, Crispus, who had remonstrated with him on his conduct. Crispus revenged himself by forming a conspiracy against him, along with Heraclius, exarch of Africa—the result of which was the overthrow of the tyrant, who was taken prisoner (October 8, 610). After being insulted and tortured, he

was beheaded, and his body dragged through the streets by the mob.

PHO'CIDÆ. See SEAL.

PHO'CION (Gr. *Phokión*), an Athenian general, of noble and unselfish character, was born about the end of the 5th c. B.C. Clinton, in his *Fasti Hellenici*, gives the date 402 B.C. He was of humble origin, but appears to have enjoyed a superior education, and to have studied under Plato, Xenocrates, and perhaps Diogenes also, from the last of whom he may have acquired his habit of indulging in caustic sarcasm. P. first attracted notice in the great sea-fight at Naxos (376), where he commanded a division of the Athenian fleet, and materially helped to secure the victory for his countrymen. Strange to say, however, we scarcely hear of him again for more than 20 years; but in 351, along with Evagoras, he undertook the conquest of Cyprus for the Persian monarch, Artaxerxes III. (Ochus), and was completely successful. About the same time, but the exact date is uncertain, he led an Athenian expedition into the island of Eubœa, where Philip of Macedon was intriguing, and inflicted a severe defeat on that powerful sovereign of Tamynæ.

In 341, he was again successful in crushing the Macedonian party in Eubœa, and in restoring the ascendancy of Athens. Two years before this, he had achieved a similar result at Megara; and in 340, when sent to the aid of the Byzantines against Philip, he acted with so much prudence and tact, and inspired the citizens with so much zeal and courage, that Philip was forced to abandon the siege, and even to evacuate the Chersonesus; while P. captured several of his ships and coast-garrisons, besides making havoc of a good deal of the Macedonian territory. Nevertheless, with just appreciation of the real weakness of Greece Proper, and of the strength of Macedon, he advocated, even in the midst of his triumphs, pacific views, and the establishment of better relations with the enemy. His advice was not taken; but the fatal battle of Charœnea, only two years afterwards, in which the independence of the Greek republics was lost for ever, proved its soundness. The murder of Philip, in 336, occasioned the greatest exultation, and Demosthenes even proposed a public sacrifice of thanksgiving, and the establishment of religious honors to the memory of the assassin, but P. resisted, and prevented so monstrous a proposal. Henceforth, his career is chiefly political. We see him struggling at Athens to repress what appeared to him the reckless desire for war on the part of the fanatical patriots, on account of which he was regarded as a traitor, but his personal honor is above suspicion. After the death of Alexander in 323, the aged P. endeavored, but in vain, to hinder the Athenians from going to war with Antipater. The battle of Cranon, next year, which prostrated his countrymen, again evinced the wisdom of his counsels; but, though very unhandsomely treated by the Athenians, he used all his influence with the conqueror (who, like Alexander, had a profound respect for him) to mitigate their hardships.

After the death of Antipater, P. was involved in the intrigues of Cassander, the rival of Polysperchon, and was forced to flee to Phocis, where Polysperchon delivered him up to the Athenians. He was condemned, by 'a mixed mob of disfranchised citizens, foreigners, and slaves,' to drink hemlock. His body, flung unburied over the borders of the state, was carried by some of his friends to Eleusis, and burned there. The Athenians soon began to raise monuments to his memory. His life has been written by Plutarch and Cornelius Nepos.

PHO'CIS (Gr. *Phókis*), a province of Greece Proper or Hellas, bounded on the W. by the Ozolian Lokri, on the N. by Doris, on the E. by the Opuntian Lokri, and on the S. by the Gulf of Corinth. It was about 792 square miles in extent. The greater part of the country is occupied by the famous mountain-range of Parnassus (q. v.). The principal river is the Cephissus. According to tradition, the most ancient inhabitants were the Leleges, Pelasgians, and Thracians, from the gradual mixture of whom the Phocians were believed to have arisen. These were finally united into a free federal state, which derives its chief historical importance from possessing the famous oracle of Delphi (q. v.). During the Peloponnesian war, the Phocians were close allies of the Athenians. In the time of Philip of Macedon, they were involved in a ten years' war, on account of their opposition to a decree of the Amphictyonic Council, concerning the use of a piece of land belonging to the temple of Delphi. This war, commonly known as the Sacred or Phocian War, ended disastrously for the Phocians, the whole of whose cities (22 in number) were destroyed, with one exception, and the inhabitants parcelled out among the hamlets.

PHŒBUS (i. e., the Bright or Radiant), a title, and subsequently a name, of Apollo. It had reference both to the youthful beauty of the god, and to the radiance of the sun, when, latterly, Apollo became identified with Helios, the sun-god.

PHENICIA (Gr. *Phoinikē*, derived either from *Phoinos*, purple, or *Phoinix*, palm-tree—both designations descriptive of the chief produce of the country; the Hebrew term *Kenaan*, Lowland, referring to its physical condition) is the name given by the Greeks and Romans to a certain territory situated about 34°–36° N. lat., bounded by the Mediterranean on the W., by Syria to the N. and E., and Judea to the S. Except where the Mediterranean set a natural boundary, the frontiers differed widely at different periods, north, south, and east, according to the gradual rise and decline of the country. Its length may be said to have been about 200 miles, while its breadth never exceeded 20 miles, making a total of about 2000 square miles. We may here mention some of the products of the soil, the exportation of which, to a certain extent, laid the foundation of her greatness. Pine, fir, cypress, cedars, terebinths, palm and fig-trees, sycamores, olive-trees, and acacias, crown the heights; while wheat, rye, and barley are found in the lower regions, together not only with ordinary fruit, but also with apricots, peaches, pomegranates, almonds, citrons, sugar-cane, grapes, bananas—all growing luxuriantly, and forming a forest of finely-tinted foliage. The land further yields silk and cotton, indigo and tobacco; and the modern inhabitants of Shur, like their forefathers of old, drive a profitable traffic with the produce of Mount Lebanon, its timber, wood, and charcoal. Flocks of sheep and goats, and innumerable swarms of bees, supply meat, milk, and honey. The sea furnished shoals of fish, and molluscs for the purple of Tyre. There are no precious metals found anywhere in P.; but it is rich in iron, and the stone-quarries of Lebanon were already worked in Solomon's time.

The question of the origin of the Phœnicians is one which has hitherto not been solved satisfactorily. Their own account, as preserved by Herodotus, speaks of their having immigrated from the 'Sea called Erythra,' a report further confirmed by another passage in his History, and by Justin. Strabo speaks of two islands in the Persian Gulf, called Tyros or Tylos and Aradus, in which temples were found similar to those of the Phœnicians; and the inhabitants of these cities stated that the Phœnicians had left them in order to found new colonies. The Erythrean Sea, in its widest sense, extends from the eastern shores of Egypt to the western shores of India; and since Genesis calls Canaan, the founder of the race, a descendant of Ham, not of Shem, some investigators have come to the conclusion, that the Persian or Arabian Gulf is the original home of the Phœnicians. Against this notion, however, weighty arguments have been brought forward, both from the genuine traditions of the people itself, as preserved, not in a corrupted Greek shape, but in their myths, in the biblical accounts, in their language, which even in its very oldest remnants (Canaan = Lowland; Sidon = Fishing-place; Gîblites = Mountain-people) is purely Semitic. It would be vague to speculate on the time at which the first Phœnician settlers entered the country: as vague as to conjecture—the Erythrean Sea being put out of the question—whence they came. So much seems certain, that they did not enter it from one region, but from several sides, and at various periods; and that only very gradually, in the course of long pre-historic centuries, they grew into one nationality, embracing the tribes that inhabited the sea-coast, or Phœnicia Proper, from Sidon to Gaza, and the cities north of Sidonia. The latter term includes the many separate states originally formed by the various *gentes*, who again, originally, had their own political existence, laws, and even worship.

Gradually, however, the larger communities extended their rules over the smaller ones, or rather combined with them for the formation of a more imposing and important state, into which the different states were merged, without, however, giving up their own individual existence or cultus entirely. The most important of these special tribes or states were the inhabitants of Sidonia—a term, however, expressive both of the inhabitants of the city and of the whole country—the Tyrians, whose settlement, according to their own traditions, was prior to any other Phœnician settlement (about 2750 B.C.); and Aradus, founded, according to the native traditions, by Arvadi, 'the brother of Sidon.' From these three tribes—of the Sidonians collectively—are to be distinguished the Gîblites with their two sovereignties of Byblus and Berytus, who differed in many respects from the former, and who it may be presumed, formed at first the ruling state of P., until they were brought under Sidonian dependency. Several smaller tribes or states are mentioned in Scripture—Arke, Sin, Hamath, &c.—but little is known about them.

Of the government and internal constitution of these states or cities, we know next to nothing. There were hereditary monarchs ruling over Sidon, Tyros, Byblus, Berytus, and Aradus, for whose confirmation, however, the assent of the people was necessary in all cases. By the side of the king stood a powerful assembly, composed of representatives of the old aristocratic families of the land, whose numbers differed at various periods. When Tripolis was founded by Tyros, Sidon, and Aradus, as a place of joint meeting for their hegemony, every one of these cities sent 100

senators to watch her special interests at the common meeting; and the senate of Sidon seems, in the 4th c. B.C., at least, to have consisted of 500—600 elders, some of whom were probably selected more for their wealth than for their noble lineage. The king sometimes combined in his person the office of high-priest.

The turbulent seething mass of the people, consisting of the poorer families of Phœnician descent, the immigrants of neighboring tribes, the strangers, and the whole incongruous mass of workmen, tradespeople, sailors, that must have abounded in a commercial and maritime nation like the Phœnicians, and out of whose midst must have arisen at times influential men enough—was governed, as far as we can learn, as 'constitutionally' as possible. The unruly spirits were got rid of in Roman fashion somehow in the colonies, or were made silent by important places being intrusted to their care, under strict supervision from home. Only once or twice do we hear of violent popular outbreaks, in consequence of one of which it was mockingly said that P. had lost all her aristocracy and what existed of Phœnicians was of the lowest birth, the offspring of slaves. As the wealth of all the world accumulated more and more in the Phœnician ports, luxury, and too great a desire to rest and enjoy their wealth in peace, induced the dauntless old pirates to intrust the guard of their cities to the mariners and mercenary soldiers, to Libyans and Lydians—'they of Persia and of Lud and of Phut,' as Ezekiel has it; although the wild resistance which this small territory offered in her single towns to the enormous armies of Assyria, Babylonia, and Greece, shows that the old spirit had not died out.

The sources for the early Phœnician history are of the scantiest description. Of the annals and state documents which filled the archives of every large city, nothing has survived except a very doubtful record, which Sanchuniatho (q. v.) is said to have compiled, about 1250 B.C., in Phœnician from official documents, and which was translated into Greek by Philo of Byblus, and a fragment of which is preserved by Eusebius. The Bible, principally Ezekiel, Menander of Ephesus, and Dios, a Phœnician, who wrote the history of Tyre from Tyrian annals, fragments of which are extant in Josephus and Syncellus, Herodotus, Diodorus, Justinus, and others, together with a very few notes scattered throughout the Church Fathers, contain the sum of all our information.

Four great periods, however, are clearly distinguishable in the history of ancient Phœnicia. The first would comprise the earliest beginnings and the gradual development of the single states and tribes, from their immigration to the historical time when Sidon began to take the lead, or about 1500 B.C. The second period dates from the conquest of Palestine by the Hebrews. Sidon had then become already the 'first-born of Kanaan,' as Genesis has it, or 'Sidon Rabbah,' the Great Sidon. The flourishing state of its commerce and manufactures appears likewise from several passages in Homer. The silver vase proposed by Achilles as a prize in the funeral games in honor of Patroclus, was a work of the 'skilful Sidonians'; the garment Hecuba offers as a propitiatory gift to Minerva was the work of Sidonian women. The gold-edged silver bowl given to Telemachus by Menelaos, Hephaistos had received from the king of the Sidonians. Ulysses is left on the island of Ithaca by the Phœnicians, who sail away to 'well-peopled Sidonia.' The gradual ascendancy of the rival city of Tyre marks the beginning of the third period, in which P. reaches the height of its power, in which her ships covered all the seas, her commerce embraced the whole earth, and her innumerable colonies flourished far and near. The first historically-recorded item of Tyre's activity is her foundation of Gades, a few years before that of Utica, in 1100 B.C. The reason of the sudden greatness of Tyre is to be found in the defeat of the Sidonians by the king of 'Askalon'—a term probably meant to represent the whole pentapolis of Philistia—about the year 1209; in consequence of which, the principal families of Sidon 'emigrated in their ships to Tyre, which [viz. the Island-city] they founded.' In the 11th c., in the time of Samuel, 'the princes of the Tyrians' are already spoken of instead of the Sidonians, as the representatives of Phœnicia. During the reigns of David and Solomon—under Hiram (980—917)—the friendliest relations existed between the two nations: both in the full bloom of their power. Each country needed what the other could supply. Hence their close alliance, which led even to common commercial enterprises in ships built by Solomon, the supercargoes of which belonged to him, while the mariners and pilots were Hiram's.

By this time, Phœnician colonization had reached its uttermost extent. In the space of three centuries (1300—1000), the Phœnicians had covered all the islands and coasts of the Mediterranean with their forts, their factories, and their cities; and their ships, which ploughed the main in all directions, everywhere found their own ports. They had colonized Cyprus, thus commanding the waters of the Levant and the coasts of Syria and Cilicia. Kition, Amathus (Hamath), Karpasia, Paphos, with its magnificent temple

of Ashera, Keryneia, and Lapothos, were some of their principal settlements in those regions. Northward, on the coast of Cilicia, they founded the cities of Myriandros, Tarsos, and Soloi. Migrating to the west, they took possession of Rhodes, Crete (cf. the Myth of Zeus and Europe), Melos, Thera, Oliaros (near Paros), and Cythera, on the coast of the Peloponnesus. To the east of the Ægean, we find them at Erythræ, and further, as masters of the islands of Samothrace, Lemnos, and Thasos with its wealth of gold mines. The Ægean Sea, with all its islands, being in their hands, they sailed thence further west, to Sicily, where they settled at Motye, on the extreme west point; founded Rus Melkarth, in the south (Heraclea Minoa); in the north, Machanath (Panormos, Palermo), and further, Melite (Malta) and Gaulos. They owned Caralis (Cagliari) in Sardinia, Minorca, Iviza (Ebusos), Elba; on the opposite, or African coast, Hippo, Utica, Hadrumetum, Leptis, and some minor island states. From Sardinia and Minorca, the indefatigable mariners went still further west—through the Strait of Gibraltar to Tarshish (the California of those days) or Spain, where they founded Gadeir or Cadiz, and in the south, Karteja, Malaka, and Abdarach. From here, having colonized well-nigh the whole of the Spanish coast, they went northwards to the tin islands (Scilly Isles), and to Britain herself. And while they thus explored the regions of the Atlantic, their alliance with the Hebrews had permitted them to find the way to the Indies by the Red Sea.

The impulse given to industry and the arts by this almost unparalleled extension of their commercial sphere, was enormous. Originally, exporters or traders only for the wares of Egypt and Assyria, they soon began to manufacture these wares themselves, and drew the whole world into their circle of commerce. As to the early and most extensive commercial intercourse between P. and Greece and her colonies, nothing can be more striking than the circumstance of nearly all the Greek names for the principal objects of oriental commerce being Phœnician, or rather Semitic—identical almost with the terms found in the Old Testament. Thus, of spices—myrrh, cassia, cinnamon, galbanum, narde, aloe, crocus, nitron, balsam, &c.; of jewels and precious stones, sapphires, jasper, smaragdus; of fine materials, and garments, byssus, karpasos, sindon, &c.; musical instruments—nabla, tympanon, sambyke, &c.; oriental plants, vessels, and even writing implements. The wealth of silver, iron, tin, and lead was chiefly got from Tartessus. The descriptions of the abundance of precious metals there verge on the fabulous. Thus, the Phœnicians are supposed to have made even their anchors of silver, when they first discovered the country, not knowing how to stow away all the silver in their vessel. What must have been the state of these mines is clear from the fact, that, even in the Roman time, 40,000 men were constantly employed as miners, and the state received a clear revenue of 20,500 drachms daily. The 'Fortunate Islands,' which, according to Diodorus, they discovered after many days' sailing along the coast of Africa, beyond the Strait of Hercules, and which, to judge from the name *Purpurarie* given to some islands off the coast of Mauritania, would seem to have been the Canaries, yielded them the shell-fish *purpura*, so useful for their dyeing manufactories. Besides their wholesale commerce carried on by fleets and caravans, they also appear to have gone about the interior of Syria and Palestine, retailing their home or foreign produce.

Although the Phœnicians were erroneously believed, by the western tribes, to manufacture all the wares in which they dealt themselves, yet no inconsiderable number of them was really their own work. None of their manufactures, however, stood in so high repute throughout antiquity as the purple dye prepared from the muricæ, a shell-fish of its coast; and none excelled more in it than the Tyrians. Purple was an almost indispensable luxury of antiquity, particularly in Asia. In temples and palaces for gods and men, purple garments, hangings, curtains, and veils were needed; and Alexander the Great found in Susa alone a store of purple worth 5000 talents. Sidon's principal production was glass—invented there, it was said, by accident; but probably the invention was derived from Egypt, where it was in use long before; the Phœnician glass, however, was always supposed to be the best. The Sidonians knew the use of most of our own contrivances—the blowpipe, the lathe, and the graver. Hardly less great was the fame of Phœnician metallurgy. Their mining operations in the Lebanon and Cyprus, where they dug for copper; in Thasos, where, according to Herodotus, they overturned a whole mountain in searching for gold; but more particularly in Iberia, where at first silver was so abundant, that hardly any labor was required to obtain it—were stupendous; and the minute description of the mining-process contained in Job (chap. xxviii. 1—11) has probably been derived from a sight of Phœnician mining-works. That they well understood how to work the metals thus gained, has been observed already. The art of founding brass must, indeed, have reached a high perfection to enable Hiram Abif to execute such works for Solomon's Temple as they are described in the Bible. No less were they familiar with the

art of imitating precious stones, and coloring glass by means of metallic oxides.

To Sidon is further attributed the pre-eminence in the glyptic and plastic arts; and the artists sent by Hiram to Solomon were skilful workers in gold and silver, in brass, in iron, in purple and in blue, in stone and in timber, in fine linen, and the engraving of precious stones. Their architecture seems to have been of a Cyclopean nature. Their vessels, originally simple rafts, gradually developed—with the aid of the Lebanon, which afforded inexhaustible supplies of timber, and Cyprus, which possessed all the materials necessary for fitting up a ship, from the keel to the sails—into a first-rate fleet, consisting of round ships, or gauli, for short or coasting voyages; war-galleys, or triremes; and fifty-oared craft, long in build, and adapted for rapid sailing or rowing. The internal arrangement of these vessels was perfect, and excited the wonder and admiration of the Greeks, by their being so splendidly adapted at once for navigation, freight, and defence. Their extraordinary three years' voyage of discovery, undertaken in the service of Necho, round Africa, going out of the Red Sea, and returning by the way of the Straits' mouth, is as well known as their voyages in the service of Solomon.

The golden age of P., during which her colonies, her manufactures, and her commerce were in this most brilliant phase, seems to have waned simultaneously almost with that of Judæa. As Solomon in the latter, so does Hiram in the former, mark the end of that peace and happiness which had made their countries rich and glorious, as no other country of their day. According to a fragment preserved in Menander, Hiram was followed by his son Balesturtus, who died after a short reign of seven years, in 940 B. C., and a long series of political calamities and civil wars ensued.

The last of Hiram's sons, Pheletus, fell, in 898, by the hands of Ithobaal, the priest of Astarte, into whose family now passed the kingdom of Tyre. He is the Ethbaal mentioned in Scripture as the father of Jezebel, and father-in-law of Ahab; and a peculiar coincidence is the simultaneous mention of the three years' drought in Judæa (to which an end was put by Elijah's prayer) and in P., where relief was obtained by Ithobaal, who seems to have stood in the odor of sanctity. It was during this unhappy period that the celebrated Elissa, better known as Queen Dido (q. v.), fled, together with some of the most aristocratic families of Sidon, to Libya, where they founded a new city (Kartachadatta = Carthage), near the spot of an ancient Sidonian settlement, about 813 B.C. The fourth and last period of Phœnician history may be dated from the middle of the 8th c., when Shalmaneser, the king of Assyria, invaded P., and besieged Tyre for five years, but without result; and there is every reason to believe that the peace concluded at the end of this period was very favorable to Tyre. But soon afterwards, P. was drawn into the struggle for the supremacy then raging between Chaldæa and Egypt, and was conquered by the former power. A further calamity befel P. at the hand of Pharaoh-Apries, who anticipated Nebuchadnezzar's intended attack on Egypt by destroying the Phœnician fleet, conquering the country, and pillaging it. These calamities produced a series of internal troubles, in consequence of which the constitution was constantly changed; and we hear now of a series of kings, and now of provisional *suffetes*—all their respective reigns, however, being of a very brief duration. From that time forward, and even before the special histories of Sidon and Tyre, which alternately possessed themselves of the hegemony of Phœnicia, constitute also the history of the country itself, and to these two cities we refer for what momentous events took place in the latter days of the once mighty empire. The battle on the Issus terminated even the shadow of P.'s independent existence, and it shared the fate of Alexander's vast empire. In 65 B.C. it became, under Roman dominion, part of Syria, and has since shared her fate for good or evil. See SYRIA, SIDON, TYRE, CARTHAGE.

Religion.—With regard to the Religion of the Phœnicians, its real character has as yet been imperfectly explicated. Deprived of all original and direct information on the subject, we have to cull what scanty notices we may from the works of Greek and Latin writers, or to gather knowledge from some vague allusions contained in the Bible. Not a scrap of native literature has been allowed to survive; and the supposed extracts from a Greek version by Philo of Sanchuniatho's Phœnician works, which we find in Eusebius—hitherto our chief source of information—must be used with more than an ordinary degree of caution. See SANCHUNIATHO. We shall therefore, without entering into futile speculations, confine ourselves to a few general and well ascertained facts; premising, however, that Phœnician theology is far from being a hopeless province, whatever it may appear now. Excavations are on foot in all directions, both in the mother-country and in the colonies, and new discoveries are being brought to light constantly.

The religion of the Phœnicians was, like all ancient Semitic religions—except that of the Hebrews—a kind of pantheistic wor-

ship of nature. While Monotheism, with the descendants of Abraham, assumed a supreme power within nature, which, according to its own free will, creates and destroys, the rest of the East assumed a Dualism: two elements, a male and a female; or two highest deities, one of whom begets, and has the power to destroy, and the other conceives and bears. These two supreme beings were sometimes merged in one deity, with male and female attributes, which spread out into immense ramifications: representatives now of the general powers of nature, now of the particular phenomena in nature, or the life of men. They had deities who ruled over the stars, the elements, the seasons; over special localities, or over certain phases of life. No nation of antiquity perhaps possessed a more endless pantheon than the Phœnicians: a circumstance easily explained by their peculiar position and relations.

Consisting originally of a variety of tribes, each of whom had their own special deities—although the supreme *Numen*, or the principle of their chief Deity, was probably the same with all—those Phœnicians who dwelt in the north differed in some respects, such as the names and attributes of certain gods, from those of the south. Besides this, it must not be forgotten that the period of Phœnician history ranges over 2000 years, and their political career, as well as their commerce, brought them in close and constant contact with nearly all the civilized nations of the then known world; and being both superstitious (as sailors and traders are prone to be), and possessed of an adaptability to which partly they owed their success in other respects, they easily, if not greedily, received into their wide pantheon those who, albeit the special national gods of others, or because of this very reason, could either harm or benefit them. It may be also that a certain easy nonchalance about these things, such as the wealthy and aristocratic classes displayed in ancient Rome and elsewhere, and the interest of the priests, who received very considerable titles of every sacrifice (oddly enough, our information on that point leaves nothing to be desired), went hand in hand to favor the gradual introduction of as many gods and goddesses as pleased the herd. Their proper divisions, however, their real names and derivations, and the history and time of their nationalization, are things which will for ever continue to puzzle investigators.

Setting aside such more or less vague and undefined names of deities as were common to the whole Semitic stock, and as they are found in the Hebrew records—like *El* (Mighty One), or (in plural) *Elim*; *Ollonim* [*Elyon*] (the Most High); *Adon* (Lord); *Melech* [*Moloch*] (King); &c.—we find in the first rank of gods (of Tyre and Sidon) Baal (q. v.) and Astarte (q. v.). Baal again occurs in two different characters, as it were—as *Baalsamin* (Lord of Heavens), the highest god ruling over the Universe, the Zeus Olympius, and Jupiter Optimus Maximus; and as *Baal Melkarth*, the special national numen. Baalsamin is originally identical with the Babylonian Bel or Baal. The third supreme Tyrian goddess was Astarte, worshipped as the very counterpart of the Sidonian Astarte. While the latter was considered a pure virgin, whose emblem was the moon, the former (the biblical Ashera) was prostituted (as Venus, goddess and planet) by prostitution. The Tyrian Astarte was principally known under the name of Tanis (q. v.), the Assyro-Persian Tanais, and was married to Baalsamin. And also to Adonis, and bore altogether the character of a goddess who delighted in elchasty.

The principal deities of Northern P.—the non-Sidonian tribes—consisted of a different trias—*El*, *Baalits*, and *Adonis*. The first was the supposed founder of the two oldest Phœnician cities of Byblus and Berytus, and corresponded to (being originally, perhaps, identical with) both Baalsamin, as the highest deity, and Melkarth, as the special god of Tyre. Baaltis, Beltis (My Lady—Aphrodite), worshipped at Byblus, Berytus, Aphaka, Arke (Architis), &c., was joined to Adonis (q. v.), whose cultus had been imported from Assyria, and is therefore unknown in the more ancient Phœnician colonies, in Africa and Spain. Byblus called him Adonis Ganas, or Ganan (perhaps Gaavan, the Exalted); near Byblus, we find him worshipped as Elyon (the Highest); as Esmun in Berytus, and perhaps also under the name of Memnon, at Apamea, where an annual mourning-festival was celebrated in his honor; further, near the river Bandus at Paltos; and at the river Belus. As Serach (the Brilliant) in Phœnician, and Kharush (the Sun) in Persian, he appears to have had some relation to the star-and-planet worship which became, under Assyrian influence, a prominent feature of the Phœnician religion.

Besides these more or less localized gods and goddesses (*Dii Majores*), a certain number of deities—states and country deities—were worshipped in common by all Phœnician states. They were called the Children of Sadik (the Just), or the Children, or the Patæki (Descendants of Plitha), or the eight Kabiri (Strong Ones). They are the maritime gods, and their images were placed on the prows of Phœnician ships. As protectors of navigation, they are identified with the Eloscuri; and again, as representatives of heat, breath, and life, they received the names of Lares and Penates. Their individual names are not generally mentioned; they seem

(cf. Esmun = eighth) to have been merely counted. Their mode of worship was most mysterious—as indeed some of the earliest mysteries were closely connected with it.

Besides these, they also worshipped certain phenomena, personified attributes, and qualities. Their planetary divinities were the Sun and his four horses—to whose worship belongs, among others, to a certain extent the annual festival of the Resurrection of the (Tyrian) Herakles, under the emblem of a column in the form of a rising flame (Chaman); the Moon with her chariot drawn by white bulls; the planet Mars (Aziz or Nergal); Jupiter (Kochab Baal); Venus (Astoret Naamah = lovely Astarte), with her voluptuous cultus; and Saturnus (Moloch, Kronos), the evil principle. The elements were revered either in conjunction with certain deities or on their own account. The water, to which sacrifices were offered both in the shape of human beings and animals or fruits, was hallowed in all its shapes—as the sea, as rivers, fountains, lakes—by which people took their most solemn oaths; the fire, in connection with the oldest deity of P.; the light (Moloch); the air and the winds; the earth and all its plants, its forests, and glens, and trees, and more especially its mountains, as the 'symbols of the High Ones,' or as 'Faces of God,' such as Mount Carmel, Lebanon, Antilibanus, and others. Of animal-worship we have only small traces.

Abstract notions and ideas were not forgotten. The Year and the Months, Day and Night, Aurora (Lilith), Age and Youth, Art and Love, had their altars. Nor were certain professions and trades without their visible patrons. Thus, there are gods of agriculture and horticulture, like Dagon, the god of grain; a Dionysos, whose Phœnician name is lost, as the god of wine-growers; a god who is the nomen of fruit-growing, of pisciculture, of mines, &c. Chthonian gods are not wanting. The god of Death—the king of the lower regions—is Muth = Death (Pluto), who is represented as a small child. His reign was shared by a goddess whose name is vaguely known as Éloti (My Goddess), and who is occasionally identified with Astarte, Dido, Anna, Persephone, Europa, and a great many other deities.

We have already touched upon the mode of worship of the Phœnicians, and the places chiefly selected for their rites. Mountains, heights, rivers, lakes, fountains, meadows, glens, were, as we said, the favorite habitations of the gods. But the Phœnicians were also amongst the first who erected temples. These were generally divided in two parts, containing the sacred arks (the mystic cists of the Greeks; and the chariots upon which the sacred objects were at times carried about. Not being intended to be prayer-houses, but as dwelling-places for special gods, they were rather small, and did not even contain the altar upon which the sacrifices were offered. This generally stood at the entrance of the temple, and around it the priests and hierodouloi danced in their service. Pure wells and an everlasting fire were the indispensable conditions of a sanctuary. The sacrifices themselves, as far as they consisted of animals, offer great analogies to those of the Jews; but the P. also offered up human sacrifices—chiefly first-born male children, as that which the suppliant held dearest—chiefly to Baalsamon, Baal Hamon, and Astarte. Such human sacrifices, or burnt-offerings took place annually at the great festivals of expiation, and further on extraordinary occasions, at the beginning of important enterprises, such as a campaign, and in great casualties; in order to expiate by one sacrifice the sin of all. The same fanaticism which fancied the gods best pleased by the offering up of what was most precious, led the Phœnician women, like the Babylonian, to sacrifice their honor in honor of Astarte, on certain occasions, so that certain sanctuaries became hot-beds of prostitution. Circumcision—another kind of sacrifice—was not common among all the Phœnician tribes, it being a rite principally sacred to Éli, the god of Berytus and Byblus.

Of festivals and pilgrimages in general, we have spoken under **FESTIVALS, GREEK RELIGION, &c.**; and what has been observed there respecting their character in Polytheism (their being to a great extent connected with the births, deaths, resurrections, and other personal phases of special deities), holds good here. No doubt, these festivals, like those of the Hebrews, and all other ancient nations, had, beside their religious, also their political and commercial significance; and P. was more particularly, by the eminent position she held in the world's trade, a place toward which flocked, on solemn occasions, pilgrims from all parts of Asia and Africa. 'Festival Embassies,' as they were called, were despatched thither from Syria, Arabia, Babylonia, Cappadocia, Cilicia, Egypt, Armenia; nay, from India, Ethiopia, Persia, and Scythia; and not until the 5th c. A.D. did these pilgrimages to P. cease entirely. One festival, is entirely peculiar to Tyre, and strangely enough, it is still celebrated by the present inhabitants of Sur—viz., the 'Wedding of the Land-water with the Sea-water.' On these occasions, the people walk in procession to the well near the town-gate, and pour some pails of sea-water into it, in order to render it clear and sweet again for a long time.

It would be vain to try, with our scanty and adulterated sources, to gain a deeper insight into the ideas attached to the names, at-

tributes, and modes of worship of the deities mentioned, or to speculate upon their moral influence upon the people of Phœnicia. That these were pre-eminently practical; that arts and manufactures flourished among them, more than among any other ancient nation; that they knew how to turn science into money; that they were, in fact, shrewd men of business—all this we know, but little more. Atheists or Pantheists, whichever they must be called in the modern sense of these words, it is extremely doubtful whether they, any more than the bulk of the Hebrews before the Exile, believed, as a body, in immortality. What was their influence upon Greece, Rome, the whole ancient and modern world, in the province of religious thought, we shall never have any means fully to ascertain. Comparative Mythology, has a vast field to explore in this direction.

Phœnician Language and Literature.—With the exception of Greek and Latin, no language was so widely known and spoken throughout antiquity as the Phœnician; and monuments of it have been found, and continue to be found, almost all over the ancient world. We can only vaguely speculate on its early history and its various phases, so long as our materials yield so little information on that point. Its decline seems to date from the 8th c. B.C., when Aramaisms crept in in overwhelming numbers. Finally, the close contact with, and the everywhere preponderant influence of the Greeks, superseded—chiefly after Alexander's time—the ancient language almost completely; and even coins with Phœnician legends occur not later than the 2d c. B.C.—An important Phœnician literature seems to have been extant as late as the 1st c. A.D., but it has disappeared from the face of the earth. After the second half of the 3d c., the language had vanished entirely in the country itself, and Jerome, who lived in Palestine, mentions the Punic, but never the Phœnician. In the west, it survived to a much later period. In Mauritania and Numidia, it remained, in a corrupted form, the reigning tongue as late as the 4th c. A.D.; and Augustine draws his explanations of Scripture from the Punic current in the 5th century. There was a translation of the whole Bible into Punic made for the use of the Punic Churches; and in and near Tripolis and Bizanium, it was the language of the common people up to a late period. From the 6th c., however, it rapidly died out, chiefly in consequence of the Vandals, Goths, Moors, and other foreign tribes overrunning the country, and ingrafting their own idiom upon it.

As a branch of the so-called Semitic family of the Hebrews, Syrians, Arabs, &c., the Phœnicians naturally are closely related to these also with respect to language. The affinity of the 'speech of Canaan,' as the Hebrew is called sometimes, with the Phœnician was indeed remarked at an early period. Augustine, Jerome, and Priscian pointed out already—and sometimes in order to back some very peculiar notions—how closely these two languages and their dialects were allied. Yet it must be obvious at first sight, that however near the two idioms may originally have stood to each other, the peculiar relations and fortunes of the two races who spoke them must have produced substantial changes in their structures in the course of time. While the ancient scriptural monuments of the Hebrews—outwardly and inwardly—exhibit a rare unity of idiom and form, the ancient hallowed utterance becoming a type and model for the later generations: the Phœnicians, on the other hand, not confined within the narrow limits of their home-country, but mixing freely with all the nations of the earth, spreading their own colonies far and near among them, opened a wide field for the 'development' of their language, or rather for its corruption, by its entering into alliance with Libyan in Africa, Sardinia, and Spain, and with Aramaic in Northern Phœnicia, Cilicia, and perhaps even in Cyprus. Thus it came to pass that the two languages which originally may have been identical in old Canaan became more and more widely divergent. To enter into a more detailed disquisition on this or other cognate points, we deem more hazardous now than we should have thought it only a very few years ago; for the more ample our discoveries in Phœnician literature have become of late, the more it becomes evident that we are only at the commencement, as it were, of Phœnician philology.

What we said of the structure of the Hebrew Language (q. v.), also holds good for Phœnician to a certain extent; and we shall therefore simply point out the most palpable differences between them. In the first instance, we observe the very strange circumstance, that what is considered an archaism or an isolated dictum in Hebrew, appears as a common expression in Phœnician. Certain grammatical terminations, obsolete in Hebrew, are in use in Phœnician—so that it would appear as if the Phœnician had retained more of the ancient Canaanite speech than the Hebrew, which gradually transformed and refined it by grammatical niceties. Another feature is the preponderance of the Chaldee, or rather Aramaic words and forms—although here again we are on very dubious ground. It might further be questioned whether our Phœnician Inscriptions—all belonging to a very late period—are not rather a faithful reflection of the Hebrew of their period, which, since the 8th c. B.C., had more and more changed into

Aramaic. So much is certain, that the original language of Canaan was perfectly free from Chaldaisms, and that these are but a late corruption—such as we also find in the later books of the Old Testament. Yet there are other features quite peculiar to the Phœnician, which—although not of sufficient importance to warrant our separating the dialect entirely from the Hebrew—are of a nature not to be explained by any Semitic analogy; such as certain differences in the pronunciation of vowels, in the treatment of consonants, the formation of pronouns; some verbal forms, and certain words entirely foreign to the Semitic. Again, a distinction is to be made between the Phœnician of P. and that corrupted form of it spoken in the western colonies, called Punic, and further, that idiom peculiar to the inhabitants of Leptis, called Libyo-Phœnician—a mixture of Phœnician and Libyan, with a vast preponderance, however, of the former element.

The difference in the pronunciation may be briefly characterized as a tendency towards an obscuring or lowering, as it were, of the vowels: thus, the Hebrew *a* is changed into *o*, the *e* into *i* or *y*, *i* into *y*, sometimes into *u*, and *o* into *u*. Peculiar is also the use of the Hebrew *ayin* as a vowel (*mater lectionis*), with the pronunciation of *o* or *u*. On some occasions, however, it is entirely omitted. The gutturals are changed at times, as in the corrupted orthography of Samaritan and Sabian, so that *L* and *R* are sometimes assimilated with the next consonant in the middle of the word, or entirely omitted, &c. As to grammar, our knowledge is extremely limited. A few undoubted facts are the termination of the nominative form in *at* instead of the Hebrew *ah*, the greater variety of genitive forms in Phœnician, the difference in the formation of the pronoun, and the identity of the article with that in Hebrew (*ha*). For the Phœnician alphabet, the model of all European alphabets, see ALPHABET.

The Literature of P., in its original form, has, as we said, perished entirely. What traces and fragments we have of it, have survived in Greek translations. But from even these small remnants, we can easily imagine the extreme antiquity, and the high importance and vast extent of these productions, which, at first, seem to have been chiefly of a theological or theogonical nature. Their authors are the gods themselves, and the writings are only accessible to the priests, and to those initiated in the mysteries. From the allegorical explanations of these exalted personages sprang a new branch of sacred literature, of which those fragments of Cosmogony mentioned above are derived. To the literary age of Taaut, Kadmus, Ophion, Esmun, &c., succeeded Thabion, Isiris, Sanchuniatho, and Mochus, who founded the schools of Priests and Prophets. These cultivated the sciences, chiefly the occult ones, magic, and the like. Nearest to the Sacred Literature stands Didactic Poetry, somewhat related to the Orphic, whose chief representatives are Sido, Jopas, &c. The erotic poetry is characterized as of a very sensuous nature, both in P. and the colonies. Of historians are mentioned Mochus, Hysikrates (Sanchuniatho?), Theodotus, Philostratus, Menander, and others; but these are mere Greek versions of their Phœnician names, and absolutely nothing has been preserved of their writings. Punic literature is also frequently mentioned by Greek and Roman writers. Geography, history, agriculture, were the fields chiefly cultivated by the colonists of Carthage and the West generally.

The monuments that have come down to us, and which not only have enabled us to judge for ourselves of the religion, the language, and the manners of the Phœnicians, are of twofold kind—they are either legends on coins and lapidary inscriptions, or Phœnician proper nouns and texts imbedded in the works of ancient classical or sacred writers. The principal and ever-growing source for our information, however, are the monumental inscriptions, of whose existence, till the middle of the 18th c., nothing was known. The most numerous Phœnician remnants have been discovered in the colonies. Richard Pococke first found, on the site of ancient Citium (Larnaka of to-day), 81 (not 83, as generally stated) Phœnician inscriptions, which he deposited at Oxford (published by Swinton, 1750). Malta, Sardinia, Carthage, Algiers, Tripolis, Athens, Marseille, have each yielded a considerable number, so that altogether we are now in the possession of about 120 monuments, either votive tablets, or tomb inscriptions. The latest and most remarkable are those now in the British Museum, discovered at Carthage a few years ago by N. Davis, consisting of votive tablets, a (doubtful) tombstone, and a sacrificial tariff, which completes another stone found some years ago at Marseille of the same nature; both setting forth the amount of taxes, or rather the proportionate share the priest was entitled to receive for each sacrifice. Another exceedingly valuable (trilingual) inscription, referring to the gift of an altar vowed to Eshmun-Asklepios, has been discovered quite recently in Sardinia. See below.

One of the most important historical monuments is the sarcophagus of Ashmanasar II., king of Sidon (son of Tennes?), found at Tyre in 1855, the age of which has variously been conjectured between the 11th c. B.C. (Ewald)—a most incongruous guess in-

deed—the 7th (Hitzig), the 6th (Duc de Luynes), and the 4th (Levy), of which we shall add the commencement, literally translated: 'In the month of Bul, in the fourteenth year that I reigned, King Ashmanasar, king of the Sidonians, son of King Tebnith, king of the Sidonians—spake King Ashmanasar, king of the Sidonians, saying: Carried away before my time, in the flood of days—in dumbness ceases the son of gods. Dead do I lie in this tomb, in the grave, on the place which I have built. I myself ordain that all the nobles and all the people shall not open this place of rest; they shall not seek for treasures and not carry away the sarcophagus of my resting-place, and not disturb me by mounting the couch of my slumbers. If people should speak to thee [and persuade thee to the contrary], do not listen to them. For all the nobles and all the people who shall open this sarcophagus of the place of rest, or carry away the sarcophagus of my couch, or disturb me upon this resting-place, may they find no rest with the departed; may they not be buried in a tomb, and may no son and successor live after them in their place;' &c.

The votive tablets bear the same character throughout, differing only with respect to the name of the man or woman who placed it in a certain sanctuary in accordance with his or her vow. Their material is mostly limestone or fine sandstone, rarely marble, and they vary from 5 to 15 inches in height, from 4 to 7 in width, and from 1½ to 4 in thickness. Beginning in most cases with the dedication to the god or goddess, or both, thus: '[Sacred] To the god..... [this tablet] which vowed N. son (daughter) of N. When he (she) heard my voice and blessed,' or 'hear my voice and bless;' &c. The sepulchral tablets generally run somewhat in this manner: 'Stone erected to....., who lived..... years.'—Much yet remains to be done. Even the palæographical side has, notwithstanding all the ready material, not been settled satisfactorily yet. One point, however, is indisputable even now. There are at least two kinds of Phœnician writing to be distinguished most clearly. The older, purer, more orthographical, and more neatly executed, is found in the inscriptions of P. herself, of Malta, Athens, Citium, and Carthage; the younger, corrupted not only with respect to the grammar and language, but also with respect to the form of the letters, which are less carefully executed, and even exhibit some strange, probably degenerate characters, is found chiefly on the monuments of Cyprus, Cilicia, Sardinia, Africa, Spain, Numidia, and the adjacent parts.

Besides the monumental sources for the language, there are a few remnants of it embedded, as we said, in ancient non-Phœnician writings. The Old Testament alone, however, has preserved its words—proper nouns chiefly—unmutilated. Later eastern writers even, not to mention the Greeks and Romans, have corrupted the spelling, to such a degree, that it is often most puzzling to trace the original Semitic words. Phœnician names occur in Suidas, Dioscorides, Apuleius, in martyrologies, calendariums, Acts of Councils, in Church Fathers (Augustine,

Fig. 1.

- i. e. Lerabbath, Letanith Pen-Baal
Uleaddan Lebaâl Ch[ammon A]
[Sh] Nadar Chanbaâl [Ben Abd]
Ashmun.....[Shema]
[Kol][a Barcla.....

'To the Lady Tanith, the face of Baal, and to the Lord Baal Chammon [is dedicated this *scil*] which has vowed Hanbaâl [the son of Abd] Ashmun..... [When he (or she) hears his voice, may he (or she) bless.]

Priscianus, Servus,) &c. The only really important remnant,

however, is found preserved — albeit fearfully mutilated and Latinized — in Plautus's *Pœnulus*, act v. s. l. of which contains, in 16 lines, the Phœnician translation of the Latin text, with more than 100 Phœnician words. Several other phrases and words are embodied in act v. ss. 2 and 3 of the same play. Yet, although there is very little doubt among scholars about the greater portion of these texts, the corruption and mutilation which they had to undergo, first at the hands of Plautus, who probably only wrote them by the ear, then at the hands of generations of ignorant scribes, have made more than one word or passage an insoluble puzzle.

Fig. 2.

The first (Latin) division, consisting of 12 lines, reads: 'CLEON. Salar[orum]. Soc[ietatis]. S[ocius], otalis]. Esculapio. Merre. Donum. Dedit. Lulbens. Merito. Merente.'
 The second (Greek) division (two half lines) reads: 'Ἀρχιμαχὶς Μάγον Ἀνδρὶ καὶ Βασιλεὶ Ἐδέρῳς Κλεων Ὁ Εὐκλῆς Ἀλφὰρ Καρα Πυδορὰ καὶ Ἀσκατῆρος ἱμῖν Πηφανάβημα ἱμῖν Μονέστη Σεκνενοεπίτην ἡλῶν κατὰ πρὸς τὰ μα.'
 The third (Phœnician) division (14 lines) reads: 'Leadun Leesunum Maarach Mischach Nechothesh Miskhal Litram Meath [100] Ash Nadar Aklin Shachisag Measher Mimelach Tishun[a] Kjoia Refia Beshat Sufetlin Chamlikat Veabd Ashmun Ben Chamlik[a].'

The first of the two specimens of Phœnician [Punic] writing subjoined is taken from one of those Carthaginian votive tablets with which the British Museum (now the wealthiest in Phœnician monuments) has lately been enriched, as mentioned before.

The emblems on it are symbolical, and refer to the deities invoked. The lower part is mutilated, but easily supplied. The date is uncertain, perhaps the 2d or 3d c. B.C.

The second is a trilingual inscription from a base of an altar, found at Pauli Gerrei, in Sardinia, and first fully explained by

Deutsch. (See *Transactions of the Royal Society of Literature*, 1864).

Its contents are briefly this: A certain Cleon, Phœnician by religion, Greek by name, Roman by nationality, a salt-farmer, vows an altar—material and weight of which are only given in Phœnician; viz., copper, a hundred pounds in weight—to Eshmun-Æsculapius 'the healer' (the Phœnician *Mearrach*, clumsily transcribed *Merre* in Latin, and *Merre* in Greek), in consideration for a cure to be performed. The date, given in Phœnician, viz., the year of two, apparently annual, entirely unknown judges, gives no clue to the time. Paleogeographical reasons, however, would place it in about the 1st c. B.C.

Among those who have more or less successfully occupied themselves with Phœnician antiquities, language and literature, and who have also, in some instances, deciphered inscriptions, we mention Scaliger, Bochart, Pococke, Barthélemy, Swinton, Bayer, Dutsch, Hamaker, Gesenius, Movers, Munck, Judas, Barges, De Sauley, Ewald, Levy, Vaux, Renan, De Luynes, De Vogué Deutsch, and others; to whose writings, contained either in special works or scattered in *Transactions of learned societies*, we refer. Very valuable are Movers's *Phœnizier*; Schröder's *Die Phœnizische Sprache*; Renan's *Mémoire* (1860), and his *Mission de Phénicie* (1870); also the relevant portions of the ancient histories of Lenormant, Duncker, and others.

PHENICO'PTERUS. See FLAMINGO.

PHENIX, the name of a mythical Egyptian bird, supposed by some to be a kind of plover, like the *kibitia*, often depicted with human arms, and called in hieroglyphs *rekh*. Others consider it to be the *benru*, or nycticorax, a bird sacred to Osiris, and represented watching in the tamarisk over his coffin. The first of these representations has sometimes a star upon the head, supposed to indicate the astronomical period of its appearance. It visited Egypt after the death of its father, and entered the shrine particularly dedicated to it at Heliopolis, and there buried its parent, putting the body into an egg or case made of myrrh, and then closing up the egg. Another account is, that the P., when about to die, made a nest for itself in Arabia, from which a new P. sprung of itself. This bird proceeded to Heliopolis, and there burned and buried its father. But the more popularly-known version is, that the P. burned itself, and a new and young P. sprung from the ashes. A less received version is, that a worm crawled out of the body of the dead P., and became the future one. The P. was, according to the most authentic accounts, supposed to visit Egypt every 500 years; the precise period, however, was not known at Heliopolis, and was a subject of contention till its appearance. The connection of the Phœnix period with that of the Sothic cycle, appears to be generally received by chronologists, as well as the statement of Herrepollo, that it designated the soul and the inundation of the Nile. A great difference of opinion has prevailed about the Phœnix period; according to Ælian, it was a cycle of 500 years; Tacitus seems to make it one of 250 years; Lepsius, a cycle of 1500 years. The P. was fabled to have four times appeared in Egypt: 1, under Sesostris; 2, under Amasis, 569—525 B.C.; 3, under Ptolemy Philadelphus, 284—246 B.C.; and lastly, 84 or 86 A.D., just prior to the death of Tiberius. The P. also appears upon the coins of Constantine, 334 A.D., viz., 300 years after the death of Christ, who was considered the P. by the monastic writers. It is supposed by the rabbins to be mentioned in Job and the Psalms.—Job xxxix. 18; Psalms ciii. 5; Herodotus, ii. 73; Achilles Tatius, iii. 25; Tacitus, *An.* vi. 28; Tzetzes *Chil.* v. 397; Lepsius, *Einleit.* p. 188; *Archæologia*, vol. xxx. p. 256.

PHENIX. See DATE PALM and PALMS.

PHO'LAS, a genus of lamellibranchiate molluscs, of the family *Pholadidae*. This family, to which the Ship-worm (*Teredo navalis*) also belongs, has the shell gaping at both ends, thin, white, very hard, sometimes with accessory valves; the two principal valves beset with calcareous inequalities, connected by fine transverse parallel ridges, forming a kind of rasp, used by the animal for boring a hole in rock, wood, or other substance, in which it lives. The animal itself is either club-shaped (as in *Pholas*) or worm-shaped (as in *Teredo*), with large long siphons, often united almost to the end, and a short foot. Several species are natives of the British coasts. They are popularly called *Piddocks*. They are used for bait, and also for food. How the pholades or piddocks excavate the holes in which they live, sometimes in clay or mud, but often in chalk, and even in much harder rocks, has been the subject of much dispute. An excavating instrument armed with silicious particles, has been ascribed to the animal, but no such instrument exists. The shell is studded with projections, in regular rows, giving it the character of a rasp or file; and the P., fixing itself firmly by its foot, which acts as a sucker, and working itself from side to side, makes use of the rasping power of its shell to enlarge its hole as it has need, so that the hole is always very exactly accommodated to the size of the occupant.

PHONETIC WRITING is the representation of speech by means of symbols for the elementary sounds of language. All alphabetic writing is essentially phonetic. The invention of letters was the invention of phonetic writing, as distinguished from the older pictorial, or ideographic, writing. From a variety of causes, however, no language has ever been perfectly represented by its spelling, and with the lapse of time the divergence has gone on increasing, since the spoken words are constantly undergoing change, while the spelling tends to remain fixed. In English, more especially, this divergence has been allowed to proceed to such an extreme that it is admitted on all hands to be a serious evil, and in recent times various schemes have been projected to remedy it. It is to these schemes of radically reformed spelling that the name of Phonetic Writing is now more especially applied; and what follows, represents the views and arguments of the promoters of the movement and sketches its history.

The earliest attempts at alphabetic writing were as strictly phonetic as the limited scheme of symbols allowed, or as the limited aim of writers required. The alphabets were confined almost exclusively to consonants; and the analysis of speech on which they were based was of course confined to the languages for which the alphabets were designed. When any old alphabet, therefore, came to be adopted for a new language or dialect, it would be found deficient in the means of writing any sounds which were not used in the language for which the alphabet was originally intended. Unless, then, new symbols were added for the new sounds, these latter must have been represented by conventional combinations of letters; and at this point the writing would cease to be perfectly phonetic.

The Sanscrit language furnishes the most convincing proof of the original phonetic character of alphabetic writing; for not only were words written exactly as they were sounded, but every change which a word underwent in utterance was consistently indicated by a change in the writing. Notwithstanding this fact, there is no language in which the etymological and grammatical relations of words are more clearly exhibited or easily traced than in Sanscrit. Our own language illustrates the same principle. No difficulty is experienced in discovering the relation between *loaf* and *loaves*, *wife* and *wives*, notwithstanding the change of *f* into *v* in the plural; nor would any difficulty be created though the *s* also were changed, as it is in sound, and the words written as they are pronounced—*lôvz*, *wîvz*.

The English language embraces in its dialects almost all the elementary sounds of all languages; and the Latin alphabet, which was adopted for its writing, was so insufficient in the number of its characters, that many new letters would have been required to adapt it for the representation of Anglo-Saxon and other words. But in place of being extended, the alphabet was reverentially accepted with all its imperfections; its deficiencies were supplemented by the use of servile or silent letters, and by various orthographical expedients; and thus our writing came to be irregular, difficult, and fluctuating. The great inconvenience, however, of representing by the same character the sounds of U and V, led to the introduction of the former as a new letter for the vowel sound, and to the limitation of the latter character to the consonant sound; and the further ambiguity arising from the want of an appropriate sign for the sound of W, led to the invention of that symbol, which, being formed by joining together two of the old V characters, was thence called 'double V'—pronounced, according to the old sound of V, 'double U.' The phonetic principle was fully recognized in these changes, and they furnish precedent for further changes, when a necessity for them shall be sufficiently felt and acknowledged.

There can be no doubt that phonetic writing would greatly facilitate the acquisition of the power of reading, and consequently of the education of children and illiterate adults; as well as tend to the reduction of dialects to one common standard, and further the diffusion of our language in foreign countries. To learn to read from perfectly phonetic characters, would be merely to learn the alphabet, and to spell would be merely to analyze pronunciation. A child at school might be made a fluent reader in a few weeks. All uncertainty of pronunciation would vanish at the sight of a word, and dictionaries of pronunciation would be superfluous.

Of all the languages which employ the Latin alphabet, the English is the worst represented; in some measure because of the rich variety of its phonic elements, but chiefly because, of all the nations which have adopted Latin letters, the English have done least to make their writing phonetic. Every attempt to correct the anomalies of our orthography has roused a host of prejudices, against which the efforts of private individuals have been powerless. The difference between phoneticians and their opponents seems to be a fundamental difference as to what really constitutes a word. The former, maintaining the *sound* to be the true word, would discard all associations dependent on letters, in order to represent the exact sound in the simplest manner; the latter,

clinging to the literal associations of orthography, argue as if the verbal cluster of *letters* in reality constituted the word. The dispute is thus, in effect, between letters and sounds: which are the signs—which the thing signified?

In phonetic writing, the eye would no doubt confound such words as *know* and *no*, *see* and *sea*, *sighs* and *size*, when written separately, as in a vocabulary; but it cannot be supposed that such words would present more ambiguity in contextual usage than they now do in utterance, subject to the same confusion to the ear. At present, we have, in fact, two languages—one purely phonic, addressed to the ear; and the other, in some degree etymological or historical, addressed to the eye. In this respect, we are in a similar position to the Chinese, with their classical ideographic language of literature, and their multitudinous vernacular dialects. In order to establish the assertion, that the phonic word (the sound) written phonetically in a sentence would be less intelligible to the eye than the written word in its present form, it is incumbent on the opponents of phoneticism to show that the simple phonic word is now less intelligible when pronounced in a sentence, than its written symbol is when read in a sentence.

The principal objection urged against phonetic writing is, that it would obscure the etymological history now discoverable in the orthography of a word. The best answer to this objection is that the traces of etymology, preserved in the present spelling, are so imperfect and inconsistent as to be of little value compared with the embarrassments they occasion in other respects.

The first requisite for the construction of a phonetic alphabet is an exact knowledge of elementary sounds, that every element may be provided with its appropriate symbol, and that no more symbols may be introduced than there are distinct elementary sounds. The latter consideration would be of importance only in connection with a general alphabet available for all languages. An alphabet for any individual language might contain symbols for compound sounds, with no other disadvantage than that of adding to the number of symbols. It would not, for instance, be of any consequence, so far as phonetic writing is concerned, whether the word *sacks* were represented by the letters *saks*, *sacs*, or *saz*, so that the symbols used were invariably appropriated to the same sounds. Orthoepists and phoneticians are not agreed as to what elements compose many of our compound sounds, such as those heard in the words *chair*, *queen*, *tune*, *I*, *out*, &c. Any attempt, therefore, at representing compounds analytically would be premature, until the analysis of the compounds had been settled. This analysis would be absolutely necessary for a general alphabet, but not so for an alphabet for any single language. Phonetic writing, then, should be separately considered, as a means of representing the elementary sounds of all languages, and as a method of symbolizing the pronunciation of any one language. We shall now show the nature of the attempts that have been made for the phonetic writing of English.

Dr. Franklin, in 1768, proposed a phonetic alphabet for English, in which new symbols were introduced for the vowels heard in the words *on* and *up*, and the four consonants heard in the words *she*, *they*, and *thing*. Many other schemes have been from time to time proposed; but the only alphabets which have been practically applied on a large scale are those of Dr. Comstock in America, and Messrs. Ellis and Pitman in England. The object of experimenters in this department has generally been to make use of existing letters as far as possible, and only to supplement deficiencies by new forms. The common alphabet has been made to furnish almost a sufficient number of characters by the inversion of some of its letters—thus, *λ*, *Δ*, *ϑ*, *ο*, *θ*, *β*, *η*, &c., as in the 'Anti-absurd' alphabet of Major Beniowski; but the best scheme of phonotypes that has yet been introduced was the joint production of Mr. Isaac Pitman, the inventor of the first system of phonetic shorthand writing, and Mr. A. J. Ellis, B.A. of Cambridge, a most accomplished mathematician and linguist. This alphabet was completed in 1847; and the experiment of its introduction was carried out with great diligence and perseverance by its promoters, until an army of philanthropic assistants became enlisted in all parts of Great Britain and America. Primers and school-books were issued, and tested on juvenile and adult classes; many works of standard literature, and even the entire Bible, were translated into the new spelling; magazines were published, and ultimately a newspaper, printed in the phonetic character, was started by the enterprising orthographic reformers. In this scheme of phonotypes, diphthongal and articulate compounds were not analyzed, and the letters of the ordinary alphabet were retained in their most common signification, seventeen new characters being introduced for unrepresented or ambiguously written sounds.

The forms of these were, in most cases, happily suggestive of the displaced orthography, and the general aspect of the writing bore such a resemblance to common typography, that any good reader of the latter could decipher the new printing with ease, after a very brief study of the alphabet. The ordinary vowel let-

ters (A, E, I, O, U) were pronounced as in the words, *am, ell, ill, on, up*; the consonants C and G were sounded as in *came* and *game*; the letters K, Q, X were sounded as superfluous, and all the other letters of the common alphabet were retained, with their established sounds. Comparing this scheme of letters with the tabulated elementary sounds of English, we find that it represents all the vowels, except the nice varieties heard in the words *air, ore, err, ask*; and that all the consonants are accurately represented except *wh*. The latter element is written by letters sounding *hoo*, so that the words *where* and *where'er* are made identical to the eye; and the sentence, 'I saw the man *whet* the knife,' is written, 'I saw the man *who ate* the knife.'

Notwithstanding these imperfections, this alphabet was found to work well among those who were disposed for a reform. The phonetic method was proved to be remarkably simple and easy in comparison with the ordinary system; the time occupied in making fluent readers was greatly reduced; and readers of phonetic printing experienced but little difficulty in the transition to reading from common orthography.

The advantages claimed for the system were chiefly: rapidity of learning to read, certainty of pronunciation, and increased facility in common reading, after the power of phonetic reading had been acquired. The chief disadvantages alleged against the system were: accustoming the eye to a false orthography, and teaching what had to be in great part unlearned after it was acquired. Whether the objectors were right or wrong, they were overpoweringly numerous, and the system failed to do more than prove that phonetic spelling greatly simplifies the acquisition of the power of reading.

The original phonotypic alphabet, described above, has been for some years discarded in the printing issued from the 'Phonetic Institution' (Bath), and a more analytic alphabet has been adopted, in which *eleven*, instead of seventeen, new forms are introduced. The latest edition of this alphabet gives the ordinary vowel letters, A, E, I, O for the sounds in the words *am, ell, ill, on*, and the letter U for the sound in *pull*; K is restored, and C rejected; J is used as in French; and the elementary sound of *wh* is still unacknowledged. The eleven new characters represent the consonants in the words *she, oath, they, and (s)ing*; and the vowels in the words, *ale, eel, alms, old, all, pool, up*.

The following are the forms of the new letters as printed and written, with a passage exhibiting their appearance in composition.

This Phonetic Alphabet consists of 34 letters, viz., the 23 useful letters of the common alphabet (*c, q, and x* being rejected), and the 11 new ones below. J is used for the French *j* (*zh*), or *g* in 'edge,' or *s* in 'vision;' hence *dj* represents *J* in *John*, and *dg* in *edge*. Tc (*t sh*) represents *ch* in *chess*, and *tch* in *catch*. Y and *wh* are consonants; *wh* being replaced by *hoo*. The vowels *a, e, i, o, u* have invariably the short sounds heard in *pat, pet, pit, pot, put*. All the other old letters have their usual signification. The italic letters in the words in the third line denote the SOUNDS of the letters.

VOWELS.

A a e e i i — O o J o W u — & s
Alms, age, air, eat — All, ope, flood — son, but,
emz, edj, et, it — ol, op, fund — son; but

DIPHTHONGS.

CONSONANTS.

ai ei oi ou — C c, H h, F f, J j.
ay, by, boy, now — she, thin, then, sing.
si, bi, boi, nou — ci, bin, den, sip.

The double letter *u*, as in *unit, unite, duty, value*, is written thus: "yunit, yunite, diuti, valu." When *ai, oi*, make a *disyllabic* diphthong, the second letter is marked with a diæresis; thus, *solfaty saiy*.

The reduction in the number of letters from that in the Ellis and Pitman alphabet is obtained chiefly at the expense of the phonetic principle, in the attempt to analyze diphthongs in writing, before their correct phonic analysis has been ascertained and settled. A method has been proposed by Mr. Bell, in which the advantages of phoneticism might be secured, so far as simplifying the acquisition of reading is concerned, without alphabetic change. Thus the orthography and sound are shown together when the words *loaf, debt, wife, wealth, straight, &c.*, are printed *loaf, debt, wife, wealth, straight, &c.*

But the question recurs: Why should established orthography be unphonetic? Or, at least, why should not some national measures be adopted to correct the anomalies of our spelling?

A similar work was undertaken by the Spanish Academy in the middle of last century, and carried out so efficiently that, at the present day, the pronunciation of any word in Spanish is immediately determined with certainty by every reader who merely knows the phonetic value of the alphabetic characters. The writing of the Italian, Dutch, and many other languages has also been successfully phoneticized. A similar result would be attained in English, if the work of orthographic revision were submitted to a competent tribunal, and if such changes as might be found necessary were duly sanctioned by authority. New letters should be added to the alphabet for the six unrepresented simple consonant sounds, Sh, Zh, Th, Dh, Wh, Ng; or, at all events, the writing of these elements should be made distinctive; and, with a few rules for distinguishing the vowel sounds, little alteration of spelling would be needed to approximate the writing of English to phonetic accuracy.

A general phonetic alphabet, available for the writing of all the sounds of human speech, is still a scientific desideratum. Such an alphabet would be of great practical value to travelers, colonists, missionaries, and philologists. Much attention has been paid to this subject of late years. In 1854, a conference of philologists was held in London, at which two rival alphabets were produced, one by Professor Lepsius of Berlin, and another by Professor Max Müller of Oxford. The former has been adopted by the Church Missionary Society, but so many local diversities in the value of the characters have been found necessary in different countries, that this 'Universal Alphabet' has been practically split up into several alphabets. The writing is, besides, overlaid with diacritical points. In the alphabet of Professor Max Müller, the latter difficulty is obviated by a free use of compound letters. The *Lectures on the Science of Language* by this author may be consulted with great advantage, both as to the physiology of speech and the history of words. In the second series of these Lectures, diagrams of the organic formation of many of the elements of speech are given, as well as a comparative table of four alphabets that have been used in the transcription of Sanskrit, and numerous references to the works of continental and other writers who have treated of the science of phonetics.

The most elaborate scheme of a universal alphabet hitherto published is that of Mr. A. J. Ellis. In this alphabet 94 sounds are discriminated by means of an ingenious system of compound letters, but the complexity of the writing forbids the possibility of its 'universal' adoption.

The chief difficulty in the construction of a universal alphabet has arisen from the want of a complete classification of elementary sounds; another difficulty has been created by an adherence to the inadequate letters of the Roman alphabet.

The resolutions of the alphabetic conference were decidedly in favor of Roman letters as the basis of the proposed 'standard' alphabet. But the wisdom of this decision may be questioned. No existing alphabet exhibits the natural relations of the sounds it represents; and, consequently, although an alphabet physiologically complete were framed, it could not incorporate Roman, Greek, or any other letters at present in use, without sacrificing the most essential qualities of a universal alphabet—simplicity and congruity. Symbols must be devised which would indicate to the eye all the organic relations discoverable by the ear between the various elements, and which would be free from the associations that would attach to adopted letters familiar to the eye with other meanings. This principle has been carried out on the system of *Visible Speech* (q. v.) by Mr. Melville Bell. For phonetic shorthand writing, see *SHORTHAND*.

PHONOGRAPH. This apparatus, invented in 1877 by Mr. Thomas A. Edison, an American electrician of note, differs from the vibrograph and phonograph. The latter are constructed to record sound vibrations graphically, while Mr. Edison's invention, which is properly called the 'Talking Phonograph,' is designed to obtain such a record that the sound vibrations resulting from articulate speech can be mechanically reproduced at a distance of time. The invention, at the time these words are written, is only in the experimental stage, but it has been successfully exhibited both in America and in Britain. As originally made, the instrument consisted of three parts—the sender, the receiver or recorder, and the transcriber; but in the P. exhibited by Professor Fleeming Jenkin before the Royal Society of Edinburgh, the last apparatus was dispensed with, the sender being constructed to fulfil both functions. This sender consists of a tube, having an open mouth-piece at one end, and bearing at the other end a thin diaphragm of metal or other substance, with a sharp point or style affixed to the center of its outer surface.

The second apparatus consists of a cylinder, about four inches in diameter, having on its periphery a V-shaped groove, cut spirally from end to end. Over this grooved cylinder a sheet of tinfoil is placed, and the sender is advanced till the point of the style lightly touches the tinfoil, over the opening of the V-shaped

cut. While the words to be recorded are spoken or sung, the cylinder is turned rapidly, the apparatus for moving it giving a lateral as well as a circular motion. The point of the style thus traverses the tinfoil spirally from end to end, and the vibrations in the diaphragm caused by the sounds, result in a series of indentations in the tinfoil. To reproduce the sounds in the 'transcriber' (or in the 'sender' under Professor Jenkin's arrangement), the cylinder is again presented to a style attached to a diaphragm, the style being pressed against the tinfoil by a slight spring. The cylinder is now made to revolve, and the motion of the style upon the inequalities in the indented tinfoil produce vibrations in the diaphragm corresponding to the sound-caused vibrations originally created in the instrument by the voice. The sounds are thus reproduced with great exactness, but with a softening of the consonants which to some extent alters the character of the voice. If the tinfoil record of sung or spoken sounds be sent to a distance, or kept for a length of time, the original sounds can be reproduced on applying it to the proper instrument. It is stated that rubbings in tinfoil can be taken from a plaster-cast of the original indented slip, so that copies may be sent to different persons, all of whom can thus reproduce the sounds so long as their tinfoil copy remains intact. In using the P. to repeat sounds, the cylinder must be revolved at the same speed as at first, otherwise the pitch will be changed. For as sound is the result of air-vibrations at known intervals, if a speech spoken in a high key were reproduced slower at the repeating instrument, the result would be to convert a treble voice into a bass one, or *vice versa*, while the lower speed would convert smartly-spoken words into a drawl.

PHONOMA'NIA. See HOMICIDAL MANIA.

PHO'SGENE GAS, known also as OXYCHLORIDE OF CARBON or CHLOROCARBONIC ACID, is represented by the formula COCl_2 , or more correctly by its double $(\text{COCl})_2$. It is a colorless, suffocating gas, which is formed by exposing equal measures of carbonic oxide and chlorine to the direct action of the sun, when they combine and become condensed into half their volume. It does not possess any acid characters, but water decomposes it into carbonic and hydrochloric acids, as is shown by the equation $(\text{COCl})_2 + 2\text{H}_2\text{O} = 2\text{CO}_2 + 2\text{HCl}$. This gas is of great interest in relation to the artificial production of Urea (q. v.) from inorganic matter.

PHO'SPHATES (in Physiology). The following phosphates* play an active part in the chemistry of the animal body.

Phosphate of Soda, which may occur under any one of the three forms $3\text{NaO}, \text{PO}_5$, or $2\text{NaO}, \text{HO}, \text{PO}_5$, or $\text{NaO}, 2\text{HO}, \text{PO}_5$. All these salts are soluble in water; and the first two have an alkaline reaction, while the third is acid. By exposure of the second of these salts ($2\text{NaO}, \text{HO}, \text{PO}_5$) to a red heat, it is converted into what is termed *pyrophosphate of soda* ($2\text{NaO}, \text{PO}_5$), in which the phosphoric acid is obviously no longer tribasic, but dibasic; and by similarly treating the third of these salts ($\text{NaO}, 2\text{HO}, \text{PO}_5$), we convert it into the so-called *metaphosphate of soda* (NaO, PO_5), in which the phosphoric acid is monobasic. It is in consequence of these changes under the action of heat, that the terms *pyrophosphoric* and *metaphosphoric* have been used as synonyms for *dibasic* and *monobasic phosphoric acids*. Phosphate of soda, in one or other of the above forms, occurs as a constituent of all the animal fluids and soft tissues of the body, but is especially abundant in the urine and the bile. There are reasons for believing that it is the second and third of these salts which occur as constituents of the animal body, although the first may possibly sometimes be found.

Pyrophosphate and metaphosphate of soda are often found in the ashes of animal fluids or tissues after the process of incineration, but they merely result from the action of heat on the two other salts. The following remarks on the derivation, elimination, and physiological importance of the phosphate of soda, are equally applicable to the corresponding salts of potash, which are always associated with them. The phosphates of the alkalies, which occur in the animal body, obviously owe their origin, either directly or indirectly, to the food; viz., directly, by being ingested as phosphates of the alkalies; or indirectly (within the system), by the action of phosphate of lime on salts of the alkalies. The elimination of these salts from the system is necessary, because they are being constantly supplied by the food; and this process is effected mainly by the kidneys and the intestinal canal. In the carnivorous animals, whose blood is much richer in phosphates than that of herbivora (the ash of the blood of the dog, for example, contains from 12 to 14 per cent. of phosphoric acid, while that of the ox or sheep does not contain more than from 4 to 6), these salts are carried off by the urine; but in consequence of the formation of free acids as products of the disintegration of the tissues, a portion of the base is abstracted from the originally alkaline phosphates, and a corresponding portion of phosphoric

acid is liberated. The originally alkaline salt is thus rendered neutral or even acid; and the occurrence of the acid phosphate of soda, $\text{NaO}, 2\text{HO}, \text{PO}_5$, in the urine is thus explained. In the herbivorous animals, on the other hand, the urine contains no phosphates, the whole of the phosphoric acid taken in their food being eliminated by the intestinal canal in the form of the insoluble phosphates of lime and magnesia. Although the general distribution of the phosphates of the alkalies in the nutrient fluids (there is 40 per cent. of them in the ash of the blood-cells; 28.4 per cent. of phosphoric acid and 23.5 of potash in the ash of cow's milk; and about 70 per cent. of phosphoric acid in the ash of the yolk of egg) is in itself an indication of their importance, the exact nature of their functions is not completely understood.

Liebig has specially drawn attention to the peculiar grouping of the acid and alkaline fluids of the animal body. The permanence of this grouping is chiefly maintained, especially in herbivorous animals, by the conversion, within the body, of alkaline and neutral phosphates into acid phosphates by the means already described. Moreover, all tissue-forming substances (the protein bodies) are so closely connected with phosphates, that they remain associated during the solution and subsequent re-precipitation of these substances; and the ash of developed tissues (such as muscle, lung, liver, &c.) always affords evidence that acid phosphates existed in the recent tissue; and, further, no exudation from the blood-vessels can undergo transformation into cells and fibres, or, in other words, become organized, unless, in addition to other conditions, phosphates are also present. Another very convincing proof of the share taken by the phosphates in the formation and functions of the tissue, is the fact, that although herbivorous animals take up a very small quantity of phosphates in their food, and although their blood is very poor in these salts, their tissues contain as large a proportion of phosphates as the corresponding parts of carnivora. Lastly, the fact, that one equivalent of the alkaline phosphate of soda ($2\text{NaO}, \text{HO}, \text{PO}_5$) possesses the property of absorbing as much carbonic acid as two equivalents of carbonate of soda, leads us to the belief, that the power of attracting carbonic acid, which the serum of the blood possesses, is due at least as much to the phosphate as to the carbonate of soda, and that, consequently, phosphate of soda plays an important part in the respiratory process.

Phosphate of Lime occurs in the organism in two forms, viz., as the neutral or basic phosphate, $3\text{CaO}, \text{PO}_5$, and the acid phosphate, $2\text{CaO}, \text{HO}, \text{PO}_5$. The neutral phosphate occurs in all the solids and fluids of the body, but is most abundant in the bones, in which it amounts to about 57 per cent.; and in the enamel of the teeth, in which it ranges from 80 to 90 per cent. It may at first sight appear inexplicable how a salt so perfectly insoluble in water as neutral phosphate of lime, can be held in solution in the animal fluids. In some fluids, as the blood, it is probably, in part at least, combined with albumen, with which it forms a soluble compound; while in other fluids, as the urine, it is held in solution by a free acid or by certain salts (as, for example, chloride of sodium), whose watery solutions are more or less able to dissolve it. If any proof is wanted of the functions of this salt in relation to the bones, it is afforded by the well-known experiment of Chossat, who showed that when too small a quantity of it is taken with the food, the bones lose more or less of their hardness and firmness, and fractures do not readily unite. Phosphate of lime, like the phosphates of the alkalies, is indispensable to cell-formation; and as a good illustration of this fact, it may be mentioned that in the mantle of the molluscs (where new cells for the formation of shell abound) this salt is far more abundant than in any other part of the body. Although by far the greater quantity of the phosphate of lime found in the body has doubtless pre-existed in the food, yet it is unquestionable, that a part of it is formed within the organism by the action of carbonate of lime on the phosphoric acid that is formed during the disintegration of the phosphorous-containing tissues, such as the brain, for example. In man and carnivorous animals, a certain portion of the phosphate of lime is eliminated by the kidneys, and the rest is carried off in the excrements; while in herbivorous animals the whole is carried off in the excrements. The acid-phosphate of lime is occasionally found in the urine of man and carnivorous animals, but it is of no practical importance. For a notice of the amount of earthy phosphates daily eliminated by the kidneys, the reader is referred to the article URINE.

Basic Phosphate of Magnesia, $3\text{MgO}, \text{PO}_5$, is analogous, both in its chemical and physiological relations, to the corresponding salt of lime, with which it is always associated. The abundance of this salt in the seeds of the cereals, and in the other ordinary articles of vegetable diet, sufficiently explains its presence in the system. A far less amount of this salt, than of the corresponding lime-salt, seems to be required by the organism, as is shown by the relative quantities in which they occur in bone (57 of the former to 1.8 of the latter), and as is further indicated by the

* The means of distinguishing between the salts of tribasic, dibasic, and monobasic phosphoric acid, are given in the article PHOSPHORUS.

fact, that, relatively, far more of this than of the lime-salt escapes intestinal absorption, and appears in the excrements.

The only phosphates remaining to be noticed are the *phosphate of ammonia and magnesia*, or, as it is sometimes termed, the triple phosphate, $2\text{MgO}, \text{NH}_4\text{O}, \text{PO}_4 + 2\text{Aq}$, which occurs in beautiful prismatic crystals in alkaline urine, and, indeed, in any specimen of urine that is beginning to putrefy, and the *phosphate of soda and ammonia*, which is occasionally found as a crystalline sediment in putrid urine.

PHOSPHATIC DIATHESIS, in Medicine, designates the condition in which there is a tendency in the urine to deposit *white gravel*. As the deposit of lithates (see **LITHIC ACID DIATHESIS**) depends upon an excessive acidity of the urine, so that of the phosphates is determined by the opposite condition—namely, by deficient acidity, or by positive alkaliescence. Alkaliescence of the urine may occur from two distinct causes—viz. (1) from the presence of the carbonate of a fixed alkali (potash, or soda), or of alkaline phosphate of soda (see **PHOSPHATES** in Physiology); or (2) from the presence of the carbonate of the volatile alkali, ammonia, which is due to the decomposition of urea. This decomposition is due to the fermenting action of the mucus of the bladder on the urea, and is explained by the equation—

The white gravel which is deposited in the second of these conditions—viz., when the urine contains carbonate of ammonia, is composed of minute shining prismatic crystals of the triple phosphate of ammonia and magnesia, which formula is given in the article **PHOSPHATES**. This salt is formed as follows: Healthy urine contains phosphate of magnesia in a state of solution. If, however, the urine become alkaline from the decomposition of the urea, a portion of the ammonia combines with the phosphate of magnesia, and forms the triple salt which is insoluble in the urine, which has now become alkaline. With this triple phosphate, there is almost always an admixture of phosphate of lime ($3\text{CaO}, \text{PO}_4$) in the form of an amorphous precipitate. The tendency to deposit the mixed phosphates (triple phosphate and amorphous phosphate of lime) is especially observed in cases of disease or injury of the spinal cord, and in disease of the bladder, particularly in chronic inflammation of its mucous coat. Upon allowing urine of this kind, which is usually pale in color, to stand for some time, an iridescent film or pellicle generally forms upon its surface, which, when examined under the microscope, is found to consist mainly of the salts we have described. Such urine speedily becomes putrid, and evolves a strong ammoniacal odor.

The above is by far the most common form of the phosphatic deposits, but, as has been already stated, the urine may become alkaline from the presence of the carbonate of potash or soda; and then, no ammonia being present, in place of the triple salt, there is a deposition of amorphous phosphate of lime, or in rare cases, of a crystalline stellar phosphate, whose composition, according to Dr. Bence Jones, is represented by $2\text{CaO}, \text{HO}, \text{PO}_4$ (*Journ. of Chem. Soc.* vol. 15). In these cases, the urine is alkaline, pale, copious, slightly turbid, of low specific gravity, and of a peculiar odor. This urine makes reddened litmus paper *permanently* blue; while ammoniacal urine causes only a temporary change in the color of the same test-paper. As the urine cools, and sometimes even in the bladder, the white sand is deposited, occasionally giving the last portion of the excreted urine a milky appearance. During perfect health, the urine often becomes temporarily alkaline during the act of digestion (when the gastric juice is especially acid); but as a general rule, the tendency to alkaliescence from a fixed alkali, and therefore to phosphatic deposits, is associated with general debility. These deposits occur for the most part in sallow, languid, unhealthy-looking persons, whose vital energies have been depressed by mental anxiety, by insufficient food, or by sexual excesses.

In both forms of alkaline urine, and therefore of phosphatic deposits, a generous diet and tonics, such as bark, wine, and the mineral acids (given before meals), are of great service; and opium is usually of great value, if judiciously administered. Small doses of benzoic acid, twice or thrice a day, with the view of restoring the acidity to the urine, and the occasional washing-out of the bladder with tepid injections, have been also found serviceable in the ammoniacal form of the disease.

PHOSPHORESCENCE. Strictly speaking, the term is applied to the phenomenon, exhibited by certain bodies, of remaining luminous in the dark for some time after being exposed to a strong light. In this sense, it is strictly analogous to, perhaps we should say, identical with, the heating of bodies by exposure to light or radiant heat. They absorb part of the energy of the vibrations which fall on them; it becomes motion of their particles; and is

again radiated from them as light or heat. Certain preparations, such as Canton's Phosphorus (q. v.), indurated limestone, &c., possess this true phosphorescence in a very high degree. With the great majority of phosphorescent bodies, however, the duration of the phenomenon is very short, rarely more than a small fraction of a second. Becquerel, who has recently studied this phenomenon with great care, has invented a very ingenious instrument for the purpose, called a *phosphoscope*. The body to be tried is placed in a small drum, which has an opening at each end. In this drum there revolve two discs, mounted on the same axle, and pierced symmetrically with the same number of holes. They are so adjusted, that when a hole in one disc is opposite to the hole in the corresponding end of the drum, the second disc closes the hole at its end of the drum, and *vice versa*. Light is admitted by one of the holes in the drum, so as to fall on the object, and it is examined through the other hole. It is obvious that when the discs are made to revolve, the object is alternately exposed to light, and presented to the eye. By a train of multiplying wheels, these alternations may be made to succeed each other as rapidly as the observer pleases, and thus the object is presented in the dark to his eye as soon after its exposure to light as may be desired. Almost all bodies are found to be phosphorescent; for instance, some kinds of pink rubies, when exposed to sunshine in this apparatus, appear to glow like live coals in the dark. The phenomenon is, in fact, precisely that which was observed by Brewster and Herschel in quinine and certain crystals of fluor-spar, and thence called *Fluorescence*. Stokes was the first to give the true explanation of these facts, and he showed it to depend upon the change of refrangibility (i. e., color) which light suffers on being absorbed and then radiated by the fluorescent substance.

The green coloring-matter of leaves, a decoction of the bark of the horse-chestnut, and the common canary glass (colored with oxide of uranium), are bodies which exhibit this phenomenon very well. Perhaps the most striking method of studying the phenomenon is to receive in a darkened room the solar Spectrum (q. v.) on a sheet of white paper; and to pass over the colored spaces a brush dipped in a solution of sulphate of quinine with sulphuric acid. No change is produced on the less refrangible rays, but in the blue and indigo spaces, a strange change of color is at once apparent where the liquid has been spread. This appears more strongly in the violet, and vividly in the spaces beyond the violet, where rays fall which excite no luminous sensation in the eye. By this experiment, the visible length of the spectrum may easily be doubled. By using the electric light, which is peculiarly rich in these highly refrangible rays, a prism of quartz, which allows them to pass very freely, and various fluorescent substances, Stokes has obtained spectra six or eight times as long as those otherwise visible. The characteristic of all these rays is, that they are *less* refrangible than those from which they are produced. The entire phenomenon is identical in principle with Leslie's photometer, in which light was measured when changed into heat by absorption, in the colored glass of which one of the bulbs of his differential thermometer was formed.

Ordinary phosphorus (from which the phenomenon took its name) becomes luminous in the dark by slight friction; whence the common trick of drawing self-luminous figures on doors and walls with a stick of phosphorus, or an ordinary lucifer-match. A similar appearance is presented by putrescent animal matter, such as decaying fish, &c.; but these are effects of slow combustion, or chemical combination, and are not properly classed among the phenomena of phosphorescence. See **LUMINOSITY OF ORGANIC BEINGS**.

PHOSPHORUS (symb. P, equiv. 81, sp. gr. 1.826) is one of the metalloids, or non-metallic elements, although, in its combining relation, it is more closely connected with the metals arsenic and antimony than with any of the members of the sulphur-group, in which it is commonly placed.

This substance affords an excellent example of allotropy; that is to say, it may be made to occur under different forms presenting different properties. See **ALLOTROPY**.

Ordinary phosphorus and the red variety are the only important forms. We shall speak of them as phosphorus and red phosphorus respectively.

Phosphorus at ordinary temperatures is an almost colorless or faintly yellow solid substance, having the glistening appearance and the consistence of wax, and evolving a disagreeable alliacious odor, which, however, is probably due to the action of the oxygen of the air upon it. It fuses at 111.5° into a colorless fluid; and if the air be excluded, it boils at 555° , and is converted into a colorless vapor of sp. gr. 1.826. If, however, it be heated to about 140° in the air, it catches fire, burns with a brilliant white flame, and is converted into phosphoric acid; and, indeed, it is so inflammable that it will catch fire at ordinary temperatures by mere friction. As the burns which it occasions are often severe and dangerous, great caution is required in handling it; and in consequence of the readiness with which it catches fire, and of its ten-

dency to oxidize when exposed to the air at a temperature higher than 32° , it is always kept in water, in which it is insoluble. It is slightly soluble in ether, but dissolves freely in benzol, in the fixed and essential oils, and in bisulphide of carbon; and by allowing its solution in one of these fluids to fall upon filtering paper, the finely divided phosphorus absorbs oxygen so rapidly as spontaneously to catch fire as soon as the solvent has evaporated. One of the most characteristic properties of phosphorus is that it shines in the dark, probably from the slow combustion which it undergoes; and hence its name from the Greek words *phos*, light, and *phoros*, bearing. Its power of forming ozone is noticed in the article on that substance. Taken internally, phosphorus is a very powerful irritant poison; and it is the active ingredient of some of the preparations employed for the destruction of vermin. Its fumes give rise to a peculiar form of necrosis of the jaw, which is very common amongst the makers of lucifer-matches, and is not followed, as in ordinary necrosis, by a formation of new bone.

Red phosphorus is prepared from the ordinary variety by heating the latter in a closed iron vessel to a temperature of 464° . It was discovered by Schröter in 1845, and is a compact solid substance of a dark red color, and with a metallic luster. It differs much in its properties from common phosphorus, being devoid of odor, does not shine in the dark, undergoes no change when exposed to the air even for years, and cannot be set on fire by friction or percussion. Moreover, it is insoluble in all the solvents of common phosphorus, and is not poisonous. It bears heating to nearly 500° without taking fire, and has a specific gravity of 2.10. By using red instead of white phosphorus for lucifer matches, there is no risk to the health of the operatives. Safety matches ignite on a surface containing a mixture of red phosphorus and sulphide of antimony.

Phosphorus is not met with in nature in an uncombined state; but it occurs in rocks of various kinds and ages, and in some countries abundantly as apatite or phosphorite, both of which are composed of phosphate of lime. It is also found in the form of coprolites or the dung of extinct animals, and more rarely as wavellite (phosphate of alumina) and vivianite (phosphate of iron). In many volcanic rocks apatite is found in minute crystals or particles, and by the decomposition of these rocks it passes into the soil. From the soil, it is extracted by plants, which accumulate it (especially in the seeds of the cereals) in quantity sufficient for the wants of the animals which they supply with food. In the animal system, phosphate of lime forms 57 per cent. of the bones; phosphates of the alkalis, especially of soda, occur freely in the animal fluids; and in fibrine, albumen, and nervous matter, phosphorus is universally present, although we do not clearly know in what form of combination it occurs.

Phosphorus was originally discovered in 1669 by Brandt, a Hamburg chemist, who obtained it from urine. Gahn and Scheele were, however, the first to discover its presence in bone, and to employ that material for its preparation. The following are the leading steps of the method now usually employed in obtaining it on the large scale. Bones are burned to whiteness, and powdered; and this bone-ash is then mixed with sulphuric acid in such quantity as partially to decompose the phosphate of lime occurring in the ash ($3\text{CaO},\text{PO}_4$) into insoluble sulphate of lime, and a soluble superphosphate of lime, whose composition is represented by the formula $2\text{HO},\text{CaO},\text{PO}_4$. The solution of the superphosphate is evaporated to a syrup, mixed with charcoal, and submitted to distillation in an earthen retort exposed to a red heat. Phosphorus rises in vapor, and is conveyed, by means of a bent tube, into water, in which it condenses in yellow drops. Two distinct processes take place within the retort. The first consists in the decomposition of the superphosphate of lime into bone-earth and hydrated phosphoric acid; while the second consists in the deoxidation, by means of the carbon, of the liberated phosphoric acid in phosphorus—a process accompanied by the evolution of hydrogen and carbonic oxide gases. After being pressed in a fused state through wash-leather, and further purified, it is forced into tubes, in which it is allowed to solidify, giving it the usual form of sticks. Soubreite (see APATITE) is now largely substituted for bones in the manufacture of phosphorus.

Phosphorus forms with oxygen an oxide, P_2O (which is always produced in small quantity when phosphorus is burned in air, but is of no practical importance), and three acids—viz., hypophosphoric acid, PO , phosphorus acid, PO_2 , and phosphoric acid, PO_3 . Of these compounds, phosphoric acid is by far the most important.

Phosphoric acid in its anhydrous state, or *phosphoric anhydride*, as it is usually termed at the present day, is represented by the formula PO_3 , and is obtained by burning phosphorus in a jar of perfectly dry atmospheric air or oxygen, when it is deposited in snow-white flakes at the bottom and on the sides of the jar, from whence it must be removed by means of a platinum spatula as quickly as possible, in consequence of its attracting moisture from the atmosphere, and placed in a perfectly dry flask. When dropped into water, it combines with it, and dissolves, evolving a

considerable amount of heat, and emitting a hissing sound, as when red-hot iron and water come together. In consequence of its strong affinity for water, this anhydride is very useful in the laboratory as a desiccating agent.

There are three hydrates of phosphoric acid, each of which possesses the properties of a distinct acid—viz., a protohydrate (HO,PO_3), a deutohydrate ($2\text{HO},\text{PO}_3$), and a tritohydrate ($3\text{HO},\text{PO}_3$). These hydrates retain their characteristic properties when dissolved in water, and combine with one, two, or three equivalents of bases to form salts, according to the hydrate employed. In the salts formed by the first hydrate, the one equivalent of water is replaced by one equivalent of base; in those formed by the second hydrate, both equivalents of water may be replaced by two of base, or one equivalent of water alone may be replaced, while the other remains in the salt as basic water; while in those formed by the third hydrate, all three equivalents of water, or two, or only one, may be replaced by base, so that this acid forms three sets of salts. Hence phosphoric acid is what is termed a *Polybasic Acid* (q. v.). The following scheme may elucidate this remark: If M, M', M'', are any three metals, whose oxides act as bases, the monohydrate HO,PO_3 forms the salt MO,PO_3 , and is monobasic; the deutohydrate $2\text{HO},\text{PO}_3$ forms the salts $\text{MO},\text{M}'\text{O},\text{PO}_3$ and $\text{MO},\text{HO},\text{PO}_3$, and is bibasic; the tritohydrate $3\text{HO},\text{PO}_3$ forms the salts $\text{MO},\text{M}'\text{O},\text{M}''\text{O},\text{PO}_3$, $\text{MO},\text{M}'\text{O},\text{HO},\text{PO}_3$, and $\text{MO},2\text{HO},\text{PO}_3$, and is tribasic.

The occurrence of phosphoric acid (in a state of combination) in the three kingdoms of nature has been already noticed in our remarks on phosphorus. The discovery of the acid was made in 1740 by Marggraf; the discovery of its true chemical nature is, however, due to Lavoisier; and that of its various modifications and its polybasicity, to the investigations of our illustrious countryman, Graham.

Phosphorous Acid occurs both as an anhydride, PO_2 , and as a hydrate, $3\text{HO},\text{PO}_2$. *Hypophosphorous Acid* ($3\text{HO},\text{PO}$) is only known in its hydrated condition, in which it occurs as a very acid, colorless, uncrystallizable syrup.

Phosphorus combines with hydrogen in three proportions to form phosphuretted hydrogen gas, PH_3 ; liquid phosphide of hydrogen, PH_2 ; and solid phosphide of hydrogen, P_2H_4 . Of these, the first alone requires notice in these pages. There are various processes for obtaining the gas; one of the simplest being by boiling fragments of phosphorus in a concentrated solution of hydrated potash, in which case, hypophosphite of potash is formed, while phosphuretted hydrogen gas is extricated. The reaction is explained by the equation, $4\text{P} + 3(\text{HO},\text{KO}) = 3(\text{KO},\text{PO}) + \text{PH}_3$. The gas thus evolved is colorless, possesses a characteristic fetid odor, and has the remarkable property of taking fire spontaneously in atmospheric air or in oxygen gas, and of resolving itself into anhydrous phosphoric acid and water—a phenomenon of which Professor Miller has given the following graphic description: 'If allowed to escape into the air in bubbles, each bubble as it breaks produces a beautiful white wreath of phosphoric acid, composed of a number of ringlets revolving in vertical planes around the axis of the wreath itself as it ascends; thus tracing before the eye, with admirable distinctness, the rapid gyratory movements communicated to the superincumbent air by the bursting of a bubble upon the surface of a still sheet of water. If the bubbles be allowed to rise into a jar of oxygen, a brilliant flash of light, attended with a slight concussion, accompanies the bursting of each bubble.'

There is reason to believe that *perfectly pure* phosphuretted hydrogen gas does not possess the power of igniting spontaneously, and that the self-lighting gas always contains a minute quantity of the vapor of the liquid phosphide (PH_2). The luminous phenomenon known as the *Will-o'-the-Wisp* has been referred to the natural evolution of the gas; there is, however, no scientific evidence in favor of this hypothesis.

Various compounds of phosphorous with sulphur, chlorine, iodine, bromine, &c., have been formed and investigated; but none of them are of any practical importance.

The medicinal uses of *phosphorus* and *phosphoric acid* have still to be considered. Phosphorus, dissolved in ether or oil, was formerly prescribed in very minute doses as a stimulant to the nervous system in certain conditions. It is, however, now rarely employed in medicine, at all events, in this country, in consequence of its poisonous properties. Several cases are on record in which children have been killed by sucking the phosphoric ends of lucifer-matches; and Christison relates an instance in which a grain and a half of phosphorus proved fatal.

The symptoms induced by this poison are those of acute inflammation of the stomach and bowels, and the only treatment that can be recommended is the administration of large quantities of mild demulcent fluids, such as milk and thin arrowroot, so as, if possible, to envelop the phosphorus, and exclude it from the action of the air in the intestinal canal; and of magnesia, with the view of neutralizing any phosphorous and phosphoric acids that may be formed.

Dilute Phosphoric Acid is included in the British Pharmacopœia, but is not very much employed. It may be prescribed in much the same cases as those in which sulphuric and nitric acids are employed, and is less likely to disturb the digestive functions, if employed for a long period, than the other mineral acids. The late Dr. Paris used to recommend it, when properly diluted, as the best acidulated drink for assuaging the thirst in diabetes. It may be prescribed in half-drachm doses.

PHOTIUS, Patriarch of Constantinople in one of the most critical periods of the struggle of that see with the great patriarchate of the West for supremacy in the entire church, was a member of a patrician family of Constantinople, and was born in the early part of the 9th century. From youth, he was distinguished by his abilities and learning; and having served in various important public offices, and especially on a diplomatic mission to Assyria (or more probably Persia), he secured the favor of the Emperor Michael, with whom P.'s brother was connected by marriage, and of the all-powerful Cesar and favorite Bardas. The Patriarch Ignatius having incurred the displeasure of Bardas and of the emperor, a weak and profligate man, whose vices Ignatius tried in vain to correct, it was resolved to deprive him of the patriarchal dignity; and the attempt to induce him to resign having failed, he was deposed with much indignity, imprisoned, and sent into exile. P. although a layman, and hitherto engaged in secular pursuits, was appointed in his stead, hurried in a few successive days through all the stages of sacred orders, and finally installed as patriarch. A council of bishops, under the influence of the court (858), declared in favor of the deposition of Ignatius, and confirmed the election of P., and the latter communicated his election to the pope, Nicholas I., in a letter which carefully suppressed all these irregularities, and represented that he had reluctantly undertaken the office. Meanwhile, however, Ignatius had privately written to Rome, and the pope sent two legates to inquire and report on the facts. A new council was assembled (859), in which Ignatius was declared deposed, and was compelled to sign the act of abdication, and P. was declared duly elected. The legates concurred, it was believed, under the undue influence of Bardas, in this sentence. But in so doing they had exceeded their power, which was merely to report to the pope; and Nicholas refused to acknowledge the sentence, and summoned the parties to a new hearing.

P., however, resisted; and a new cause of dispute having arisen in regard to the jurisdiction claimed by the see of Constantinople in part of the province of Illyricum and among the newly-converted Bulgarians, the council, which Nicholas called at Rome in 862, annulled the acts of that of Constantinople and of the legates, declared P.'s election uncanonical and invalid, deposed and excommunicated him, and reinstated Ignatius in his see. Being supported, however, by the emperor, P. retained possession, and not only refused to yield, but retaliated on the pope by assembling a council at Constantinople in 867, in which the question was removed from the region of a personal dispute between the bishops to a controversy of doctrine and discipline between the churches of the East and West themselves. In this council, P. first brought forward distinctly certain grounds of difference between the churches, which, although considerably modified, afterwards led to their final separation. In all these doctrinal differences, the council condemned the Western Church, excommunicated Nicholas and his abettors, and withdrew from the communion of the see of Rome. During the life of the Emperor Michael, the authority of P. remained without further question; but on Michael being deposed and put to death by Basilus the Macedonian in 867, P., by that capricious exercise of imperial authority of which these times supply so many examples, was deposed, and banished to Cyprus, and Ignatius reinstated; soon after which, in 869, the council known as the eighth general council, at which Pope Adrian II.'s legates presided, was assembled at Constantinople. The whole case was revised. P. being convicted of fraud, forgery of documents, and uncanonical usurpation, was condemned and excommunicated, the rights of Ignatius established, and the intercommunion of the churches restored. From his exile at Cyprus, P. appealing successfully to Basilus, obtained his recall, and, on the death of Ignatius, was re-appointed to the patriarchate.

The pope of the time, John VIII., yielding to expediency, or deceived by false reports, acquiesced in the proceeding—a supposed act of womanish weakness, in the opinion of some, by obtaining for John the *feminine sobriquet Joanna*, was the origin of the fable of POPE JOAN (q. v.). P., in 879, assembled a new council at Constantinople, renewed the charge against the Western Church, and erased from the creed in the article on the PROCESSION OF THE HOLY GHOST (q. v.), the word *filioque*, which had been inserted by the Latin Church. The separation of the churches, however, was not completed till the time of Michael Cerularius. See GREEK CHURCH. P. did not die in possession of the see; he was deprived, and exiled to Armenia, by Leo, sur-

named the Philosopher, the son and successor of Basilus, in 886, and died soon afterwards, probably in 891. The character of P. is, of course, differently represented by the Easterns and the Westerns, the latter of whom ascribe to him every excess of craft, violence, and perfidy. The Greeks, on the contrary, defend his memory. It is hardly possible, however, to doubt the substantial justice of the accusation made against him. The impression produced by a review of his chequered career, and of the more than equivocal proceedings with which his name is connected, is made more painful by the evidences of rare genius, and profound and cultivated literary judgment, which his works reveal. His chief remains are (1.) *Myriobiblon*, called also *Bibliotheca*, a summary review of the works which P. had read, with an epitome of the contents, and a critical judgment of their merits. The number of works thus criticised is no less than 279; and as many of these are now lost, the judgment and remarks of such a man are of great value for ancient literary history. (2.) *A Leicon*, which was edited by Hermann, and afterwards by Porson (or rather from his manuscript by Dobree) in 1822. (3.) *The Nomocanon*, which is a collection of the acts and decrees of the councils up to the seventh ecumenical council, and the ecclesiastical laws of the emperors for the same period. (4.) Several minor theological treatises. (5.) A collection of letters, many of them extremely interesting and elegant. There is one in which, from his exile, he appeals to be permitted the use of his books, which, for beauty of composition, delicacy of sentiment, and the genuine eloquence of a scholar's love of learning, can hardly be surpassed in ancient or modern literature. A complete edition of his works is found in Migne's *Patrologiæ Cursus Completus*, in 4 vols., royal 8vo.

PHOTO-GLYPHIC ENGRAVING. See PHOTOGRAPHIC ENGRAVING, PHOTOGRAPHY.

PHOTOGRAPHIC ENGRAVING. Several ingenious attempts have been made to prepare engraved plates by photogenic action; the earliest of these dates as far back as 1827, which was six years previous to the introduction of the Daguerreotype process, and was the invention of M. Nicéphore Niepce of Paris, who first discovered that thin plates of bitumen were curiously affected by light; he therefore coated metal plates with a thin layer of bitumen, of the kind called *Jews' Pitch*, and placed them in a camera obscura, so arranged that he could insure their exposure to the same image for several hours. The plate was then submitted to the action of oil of spike, which readily dissolved those portions not acted upon by the light, but exerted little action upon the remainder; the metal exposed by the solution of the bitumen was then acted upon by acid, which produced a complete etching-plate, the picture-part being protected by its bituminous varnish from the action of the acid. About ten years after, M. Fizeau invented another process; he took a Daguerreotype picture, and acted upon it with a mixture of nitric, nitrous, and hydrochloric acids, which, without affecting the silver where the metal was free from the photographic action, quickly attacked the dark portions of the picture in greater or less degree according to their intensity, and thus etched the picture in the plate. The action at first produced only a slight erosion, because a coating of chloride of silver was formed; but upon this being removed by a solution of ammonia, it was repeated until a greater depth was gained. This, at the utmost, was not very great, and never sufficient to print from; but he most ingeniously met this difficulty by coating the plate with a drying oil, which was carefully wiped from the surface, and left to dry in the engraved parts; afterwards, he electrolysed the level surface with gold until the necessary depth was obtained, after which the plate was boiled in a solution of caustic potash, which removed the varnish.

The plate in this state required a little of the engraver's art to touch it up, and remedy some defects inherent in the process; and then, to prevent injury to the soft metals—silver and gold—employed, an electrolyte plate was taken for the printer's use. But these processes, notwithstanding their extreme ingenuity, never thoroughly succeeded, and have been abandoned for the more satisfactory inventions of Dr. W. H. Fox Talbot; these were patented in 1852 (No. 179) and 1858 (No. 875). By his first plan, a steel plate, such as is prepared for engravers, is first dipped into a solution containing acetic and sulphuric acids; it is then coated with a mixture containing a solution of fine gelatine and bichromate of potash. This is impressed with the image of a photographic negative by exposure in the copying-frame, and washed. The film of gelatine is previously yellow, but the action of the light through the light parts of the photograph change it dark brown, but the remainder is unaffected; consequently, a picture is produced of a light yellow color on a brown ground. The action of the light is to reduce the bichromate of potash, and, consequently, to render the gelatine combined with it insoluble; whilst those portions which have been protected from the action of the light by the dark parts of the negative, are still readily soluble in water, and can be removed by soaking: the insoluble

portion thus forms a raised picture, which is submitted to a solution containing bichloride of platinum in certain proportions, with a little free acid and water, which etches out the exposed parts of the plate, and renders it fit for engraving from. In the same specification is added an ingenious method of giving to the whole picture the appearance of an engraving; it consists in spreading over the gelatinized plate, when nearly dry, a piece of very fine muslin, and evenly pressing it so as to leave an impression of the cross-lines of the textile material upon the surface. By his second specification, he alters the process so far as the washing is concerned, after obtaining the picture on the gelatinized plate, and thus obviates some injuries to which it was thereby rendered liable.

Instead of washing, the gelatinized surface is thinly but very evenly covered with finely-powdered copal or other resin, and the under-side of the plate exposed to sufficient heat to melt the resin, so as to form a thin varnish over the whole. The etching fluid is then poured on, and, notwithstanding the resin coating, it acts through to the metal, and eats in wherever the gelatine has not been rendered insoluble by the action of the bichromate of potash and the light. When sufficiently etched, it is washed in clean water, and the plate is freed from the resin and gelatine. Two modifications of this process are given in the Specification, to which the reader is referred for fuller particulars. Dr. Talbot calls his process *Photo-glyphic Engraving*. The same processes, with some modifications, applied to zinc constitute *Photo-zincography*, and to stone, *Photo-lithography* (q. v.), both of which are largely practised; and they have been brought to such extraordinary perfection, especially by the late Sir Henry James, Director of the Ordnance Survey, and by an eminent firm in Brussels—Messrs. Simonau, Toovey & Co.—that quite a new era is opened up in the art of engraving and printing.

These processes are particularly well adapted for copying maps and printed books, and Sir H. James has consequently turned it to a most profitable account in producing reductions of the large plans of the Ordnance Survey to the proper sizes of maps; and he has also published perfect fac-similes of Doomsday Book and other important documents. See under PHOTOGRAPHY.

PHOTOGRAPHY (Gr. *phos*, light, and *grapho*, I write). From the following brief sketch of the history of this art, it will be apparent that its present advanced form has resulted from the combination of various discoveries in reference to the nature and properties of light made by investigators at different periods. Each inquirer has availed himself of the results obtained by previous students, adding to the common stock the results of his own investigations. The progress has been far more rapid than in most of the sciences which have been built up in a similar manner. Like other branches of chemistry, it owes its origin to the alchemists, who, in their fruitless researches after the Philosopher's Stone and *Elixir Vita*, produced a substance to which they gave the name of *Luna Cornea*, or Horn Silver, which was observed to blacken on exposure to light. This property of the substance constitutes the leading fact upon which the science of photography is based. More recently, the illustrious philosopher Scheele made experiments with the substance in question, with a view to determine the effects produced upon it by different rays in the solar spectrum. His words are these (published in 1777): 'Fix a glass prism at the window, and let the refracted sunbeams fall on the floor; in the colored light put a paper strewn with *Luna cornea*, and you will observe that the horn silver grows sooner black in the violet ray than in any of the other rays.' Still more recently, the names of Wedgwood and Davy (1802), and of Niepce and Daguerre from 1814 to 1839, occur as followers in the path indicated by Scheele and the earlier savans; and in the early months of the year 1864, the attention of the Photographic Society of London was occupied by the endeavor to establish the authenticity and true photographic character of some pictures found in the library of Matthew Boulton, and believed to be true sun-pictures by James Watt, the celebrated engineer; thus offering great probability that the mind which produced the wonders of steam-power, had also been engaged in the same investigations which have resulted in the present more extensive development of photographic science.

Most of the experiments alluded to may be said to have been based upon the fact, that the salt of silver, called by the ancients *Luna cornea*, and by modern chemists chloride of silver, is highly sensitive to the influence of light. But such observers must have been fully aware that this substance is not the only one affected by light, for it had been long noticed that the light of the sun does not fall upon any surface without leaving traces of its action thereon. It cannot be absorbed or reflected without in some way modifying the structure and properties of the exposed surface. Even the brick and stone of which our houses are built become blanched by its influence, and those portions on which the shadows of trees or other detached objects fall are perceptibly darker than those exposed to its full force; with the knowledge,

therefore, of this all-pervading influence before their minds, the investigations of scientific photographers have been directed to the production of surfaces either of metal, paper, or glass, so imbued with chemical substances as to possess a maximum amount of sensibility to this subtle agent—light.

There seems but little doubt that some of the acute-minded men who investigated the phenomena of the influence of light must have made use of the beautiful invention of Baptista Porta of Padua, known as the Camera Obscura (q. v.); for the pictures of natural objects formed on the inner surface of this instrument would readily suggest its use in combination with the *Luna cornea*. In the researches of a later period, the camera was used. The earlier attempts by its means failed, however, owing to the want of a power of fixing the images produced by the lens—i. e., of dissolving the unchanged *Luna cornea*, without acting on the reduced silver of which the image was formed. That want having, by means of chemical investigation, been supplied, the science of photography has become firmly established in its principles, and the practice of it as an art is diffused all over the civilized world.

The honor of having been the first to produce pictures by the action of light on a sensitive surface is now very generally conceded to Thomas Wedgwood, an account of whose researches was published in 1802 in the *Journal of the Royal Institution*, under the title: 'An Account of a Method of copying Paintings upon Glass, and of making Profiles by the agency of Light upon Nitrate of Silver; with Observations by H. Davy.' In the experiments detailed in this communication, white paper and *whit-leather* were imbued with nitrate of silver, and exposed either in the camera obscura, or under the leaves of trees or wings of insects. The result was, that the shadows preserved the parts concealed by them white, while the other parts became speedily darkened. The misfortune was, that no attempts made either by Wedgwood or Davy to prevent the uncolored portions from being acted on by light (or, as we now say, to *fix* the picture), were successful. This operation was not effected in a thoroughly efficient manner until Sir John Herschel suggested the employment of hyposulphite of soda for that purpose. Many other fixing agents had been previously used, as ammonia, iodide of potassium, chloride of sodium, and bromide of potassium, suggested by Mr. Fox Talbot; none of these, however, were found equal to the salt proposed and successfully used by Sir John Herschel.

M. Niepce of Chalou-on-the-Saône was the first to enjoy the satisfaction of producing *permanent* pictures by the influence of solar radiations. This was accomplished in 1814, and the name chosen to designate his process was *heliography*—a name in some respects preferable to photography. It consisted in coating a piece of plated silver or glass with a varnish made by dissolving powdered asphaltum to saturation in oil of lavender, taking care that the drying and setting of this varnish be allowed to take place in the entire absence of light and moisture. The plate so prepared was then exposed in the camera obscura for a length of time, varying from four to six hours! according to the amount of light. A faint image only is at first visible, and this is afterwards developed and fixed by immersion in a mixture of oil of lavender and oil of white petroleum; the plate being finally washed with water, and dried. Light has little or no action on these heliographs; they should, however, be protected from moisture. M. Daguerre improved on this process, by suggesting the use of the resins obtained by evaporating oil of lavender, whereby a great increase of sensibility was secured.

Adopting date of publication as the best evidence of discovery, the next process offering itself for consideration is that for photogenic drawing by Mr. Henry Fox Talbot, communicated to the Royal Society on the 31st January 1839, just six months previous to the publication of Daguerre's process. It consisted in immersing carefully selected writing-paper in a weak solution of common salt, and drying it. After this, a dilute solution of nitrate of silver was spread over one side, and the paper again dried at the fire. When dry, it was fit for use, the sensitiveness being much increased by alternate treatment with saline and argentine solutions. Paper thus prepared yielded impressions in an incredibly short time, and nothing could be more perfect than the images it gave of leaves and flowers, the light passing through the leaves delineating every ramification of their nerves. Considerable improvement in point of sensibility was attained by Mr. Talbot in the following year, 1840, by the employment of iodide of silver on paper, as a foundation, to be washed over with a mixture of aceto-nitrate and gallo-nitrate of silver, just previous to exposure in the camera. Paper so prepared was so sensitive that an exposure of less than a second to diffused light was enough to produce an impression. After exposure and development, the picture was washed, and fixed by immersion in a solution of bromide of potassium.

Niepce and Daguerre accidentally discovered that they were conducting experiments of a kindred character, and shortly afterwards entered into a partnership. The former, however, dying in July 1838, a new deed of partnership was signed between his

son Isidore and M. Daguerre, which resulted in the publication, in July 1839, of the process known as the Daguerreotype. This was not done, however, until the French government had passed a bill, securing to M. Daguerre a pension of 6000 francs and to M. Isidore Niepce, the son of the Niepce, a pension of 4000 francs, both for life, and one-half in reversion to their widows. This handsome conduct on the part of the French government was based upon the argument, that 'the invention did not admit of being secured by patent, since, as soon as published, all might avail themselves of its advantages; they, therefore, chose to enjoy the glory of endowing the world of science and of art with one of the most surprising discoveries that honor their native land.'

The discovery of the Daguerreotype may be said to have arisen from the dissatisfaction entertained by Daguerre with the insensibility of the bituminous surfaces of Niepce, which induced him to turn his attention to the salts of silver as a means of producing a higher degree of sensitiveness. This he attained by exposing a highly polished plate of silver (attached, for greater strength, to a copper plate) to the vapor of iodine, by which pure iodide of silver was formed on the surface. The plate so prepared was exposed in the camera obscura for a length of time (20 minutes), which was then considered very short. No apparent effect was produced on the plate, the image being a latent one, arising from a minute molecular disturbance caused by the impact of the actinic rays. The latent image was afterwards developed by exposing the plate to the vapor of mercury; and it is this development of a latent image, reducing as it did the time of exposure from hours to minutes, which truly constituted a new era in the science of photography. It is further due to Daguerre to state, that, while his processes for the purpose were imperfect, he still succeeded in fixing his pictures, although it was reserved for Sir John Herschel to announce the great suitability of the hyposulphites for dissolving the haloid salts of silver. The sensibility of the silver plate was still further increased by Mr. Goddard, who suggested, in 1839, the association of the vapor of bromine with that of iodine; while M. Claudet, in 1840, employed chlorine. It is a remarkable fact in connection with these discoveries, that the elder Niepce should, so early as 1820, have tried the treatment of silver plates with the vapors of sulphur and phosphorus.

But the progress of this interesting science received a very important impulse from a discovery, which at first scarcely appeared to have any connection therewith. In 1833, Braconnot gave, in the *Annales de Chimie*, an account of a new substance obtained by the action of nitric acid on starch, sawdust, linen, and cotton-wool. He named this substance Xyloidine; it was very combustible, and burned almost without residue. In 1838, Pelouze, in the *Comptes Rendues*, suggested its application in artillery. He says, 'Plunge paper in nitric acid (specific gravity 1.500), leave it in for two or three minutes, and wash: a kind of parchment is obtained, impermeable to moisture, and extremely combustible.' Dumas, in 1843, proposed the name Nitramidine, and suggested its use for fireworks. At a meeting of the British Association held at Southampton in the year 1846, Herr Schönbein, an eminent Prussian chemist, read a paper on the preparation of explosive cotton, a substance obtained by acting on ordinary carded cotton by a mixture of strong nitric and sulphuric acids. This explosive cotton was afterwards found to be soluble in ether; and the solution so prepared was named collodion by its discoverer, Mr. Maynard, who, in 1848, published in the *American Journal of Medical Science* the formula for its preparation. This ethereal solution having a certain proportion of alkaline iodides and iodide of silver added thereto, constituted the collodion first employed by Mr. Archer, who, although deserving the credit of having first arranged a practicable working process with collodion for its basis, without which photography could not have attained its present high position, says, in the second edition of his *Manual*, 'it is due to Le Gray to say that he was the first to publish an account of collodion as a photographic agent; thus illustrating the candor with which Mr. Archer admitted his claim to be considered the first to suggest its value in photography. Mr. Fallon Horne and Mr. Fry materially assisted Mr. Archer in bringing his experiments to perfection. Although the announcement at the British Association in 1846, was to the effect that Schönbein had made cotton as explosive as gunpowder, no particulars were published. In April 1847, he obtained a patent; but in October 1846, Mr. Thomas Taylor had published a similar method to that patented.

By one of those singular freaks of fortune which sometimes occur, Daguerre succeeded in identifying his name with his process; but Mr. Archer was not so fortunate as to give his name to the process which he invented. A reference to the article COLLODION will show that (bearing in mind that glass perfectly cleaned forms the supporting medium) the sensitive surface is obtained by the conversion of the soluble iodides and bromides in the collodion film into iodide and bromide of silver by immersion in a solution of the nitrate of that base, and that it is exposed in the camera while still moist with adherent nitrate, the latent image

so obtained being developed with a mixture of protosulphate of iron, acetic acid, and alcohol, fixed with hyposulphite of soda, and varnished.

In the Niepceotype or albumen process, glass plates of proper thickness and quality, and perfectly clean, are coated with Albumen (q. v.), to which an alkaline iodide has been added. When perfectly dry, they are immersed in a solution of nitrate of silver, when an immediate decomposition takes place; iodide of silver being formed in the albumen film, and nitrate of potash or ammonia remaining in solution. The plate is then freely washed with water, dried, exposed, developed with gallic acid, and fixed with hyposulphite of soda.

A retrospective glance will show the reader that four processes have now been passed in review; and on a little consideration, it will be seen that one principle pervades the whole—viz., the production of a latent image by the action of light on iodide and bromide of silver, its subsequent development by suitable means, and the final removal of the unaltered portions of the sensitive film by a fixing agent.

Among these processes, the 'collodion' has achieved a well-merited distinction, and until quite recently, was so generally employed as almost entirely to exclude the others. Various modifications of this process have been from time to time suggested to meet the exigencies of landscape photography. It has already been stated that the collodion film is exposed while still moist with adherent nitrate of silver solution; and this method is especially applicable to the taking of portraits, where it is desired to reduce the time of exposure to a minimum; but for landscape purposes, it is by no means so imperatively necessary to curtail the time of exposure; and as the necessary apparatus and materials for sensitizing and developing a wet plate are somewhat cumbersome for field-work, it was suggested by the Abbé Despratz to wash off the free nitrate from the surface, and allow the film to dry in the absence of light. It was subsequently found that previous to drying, the plate should be immersed in a solution of albumen, tannin, malt, coffee, or almost any organic body, the object being to preserve a degree of porosity in the film.

In 1864, Syce and Bolton of Liverpool introduced a 'Dry Collodion Process,' different from all of the various modifications previously in use. Instead of forming a bromo-iodide of silver in the film by immersing a plate coated with collodion containing alkaline iodides and bromides in a solution of nitrate of silver, they added the silver salt to the collodion, and so formed an emulsion, in which the insoluble and sensitive salts remained in suspension. This was known as the collodio-bromide or emulsion process, and as wrought out and improved by Bolton and others, gradually superseded all other forms of dry process for landscape and architectural work.

Although the collodio-bromide was much more sensitive than any of its predecessors, it still left much to be desired, and many experiments were made with a view to remedy the defect. In 1871, Dr. Maddox published the first workable formula for the preparation of an emulsion, in which gelatine took the place of collodion; and in 1873, Mr. Kennett patented a method whereby the washed gelatino-bromide emulsion was converted into a dry pellicle that would keep indefinitely, and which simply required to be dissolved in water. Excellent results were obtained by this method, but it failed to attain popularity. Early in 1878, Mr. Charles Bennett published details of a method by which he had produced some marvelous results, and attained a sensitiveness infinitely greater than that of wet collodion. The results fairly surprised the general body of photographers, and at once awoke them to a sense of the value of the process. It was eagerly tried by almost every operator in the country, and in a year or two had almost entirely superseded wet collodion for portraiture in the studio, as well as for landscape and architectural work. A fairly lighted landscape may be got by an exposure of a small fraction of a second, and the development of the image is effected by simply immersing the plate in a weak solution of pyrogallol acid and ammonia, to which has been added a trace of bromide of potassium.

The object of the photographer at the present day, whatever may be the process he employs, is the production of a negative, an image in which the lights and shadows are reversed, the highest lights being represented by an almost opaque deposit, and the deepest shadows by almost clear glass. This is used as a *cliché* from which to print positive impressions, generally on paper coated with albumen and chloride of silver, but occasionally on compounds of carbon, gelatine, and bichromate of potash, and other substances.

PHOTO-LITHOGRAPHY is the application of photography to engraving on stone. A lithographic stone is coated with a mixture of water, gum-arabic, sugar, and bichromate of potash, dried in the dark, exposed in the camera, or under a negative. The effect of the luminous action is to render the gum almost insoluble. A solution of soap is then applied which serves the double

purpose by its decomposition of yielding a greasy printing-surface, and by its solvent action to remove those portions unacted on by light: its action being inversely proportionate to the extent to which the gum was fixed by the light. In this condition, the stone is freely washed with water, and when dry, receives a coating of printer's ink from the roller, which, by uniting with the soap, gives additional body to the picture. This process was patented by Mr. W. E. Newton; but, in common with others of a kindred character, the resulting pictures were invariably deficient in middle tint, possessing a degree of hardness unpleasant to the eye.

PHOTO-XYLOGRAPHY, the application of photography to wood-engraving. One process, patented by Mr. Newton, consisted, first, in rubbing into the wood-block a varnish, composed of asphaltum, ether, and lamp-black, to saturate the pores. Collodion was then poured on as in the ordinary Collodion process (q. v.). The surface was then sensitized, and exposed in the camera, the picture being developed in the usual way. The thickness of the united films was, however, found to interfere with the operations of the engraver.

W. Crookes, F.R.S., subsequently simplified the method of producing an impression on wood-blocks by rubbing them over with a mixture of oxalate of silver and water, and exposing under a negative. The advantage of this process was, that it did not require any treatment of the block for the purpose of fixing after exposure, as if kept from the continued action of light, the block would keep long enough for the engraver to work out the details with his tools. It is fair to assume, notwithstanding the ingenuity displayed in these processes, that some insuperable objection exists in both of them, since neither has been adopted to much extent.

PHOTO-MICROGRAPHY consists in the enlargement of microscopic objects, by means of the microscope, and the projection of the enlarged image on a sensitive collodion film. The manipulatory details are the same as in the Collodion process (q. v.), only that, on account of the delicate nature of the markings to be rendered, it is necessary to employ a collodion yielding what is termed a structureless film. The principle upon which the enlargement is effected is that of the conjugate foci. This branch of microscopic and photographic science has proved a useful aid in the study of the sciences of Botany, Physiology, and Entomology, by delineating, with unerring accuracy, woody fibre, ducts, starch granules, muscular fibre, blood discs, nerve papillæ, &c. Among the numerous experimenters attracted by this interesting study, Dr. Maddox is one of those who have attained especial renown; and by him, minute animalculæ, all but invisible by unassisted vision, have been magnified to a superficial area of three square inches, in which the most delicate details have been faithfully preserved. By reversing the arrangement necessary for these enlargements of microscopic objects, it will be seen that minute photographs of engravings, or other objects, may be produced which would require a microscope for their inspection. In this way communication was maintained, during the investment of Paris, when copies of letters and newspapers were inserted in quills, and fastened to carrier pigeons; and this is really by no means so difficult to accomplish as it may seem at first sight, since photographs no larger than a pin's head have been produced, including in that small space portraits of no less than 500 eminent men.

CELESTIAL PHOTOGRAPHY comprehends the application of photography to the automatic registration of celestial phenomena. The laborers in this field of scientific research have been numerous both in America and Europe; the name of Mr. Warren de la Rue, however, stands out so prominently before all others, that in the limited space at command, it is scarcely necessary to do more than notice the leading facts established by his researches. Not the least interesting of these is the demonstration of the sphericity of the moon by means of the stereoscope and lunar photographs, also the determination of the nature of many of the more obscure markings on its surface, by which elevations are clearly distinguished from depressions. The faculæ or spots on the sun's surface have also been photographed, and examined stereoscopically, by which they have been found to arise from elevations of the outer regions of the photosphere. Photographs have also been obtained of Lyra and Castor, and of the nebula in Orion. The instrument employed for the purpose is called a Photo-heliograph. Photography has also been extensively employed in connection with solar and stellar spectroscopy, and in the hands of Lockyer in England, Draper in America, and Vogel in Germany, has rendered much service to astronomical science.

PHOTO-GALVANOGRAPHY, a method of producing from a photograph an electrotype copper-plate in a state fit for printing. It was invented by Mr. Paul Pretsch of Vienna, and is dependent on the property which unaltered gelatine possesses of swelling up in water. In order that a plate should be fit for engraving, it is of course essential that it should have on its surface elevations and

depressions corresponding to the lights and shadows of the picture. Accordingly, the first operation consists in coating a glass with a solution of gelatine and bichromate of potash, and when this is dry, exposing the same to light under a negative. In accordance with the above-named property of gelatine, it will be found, on applying water to the film, that the portion unacted on will swell up, while those parts upon which the actinic rays have exercised their full influence, will remain unchanged by the water. From the image thus obtained, a gutta-percha mould is prepared and its surface made conducting by means of levigated graphite or bronze-powder. Copper is then deposited thereon by the electrotype process, and the plate thus produced is printed from in the ordinary way.

PHOTO-GLYPHOGRAPHY is a process invented by Mr. Fox Talbot, for etching a photograph into a steel plate. It consists in coating the plate with a mixture of bichromate of potash and gelatine, and exposing under a negative. The effect of this treatment is to render the gelatine insoluble, just in proportion to the intensity of the light's action, after which a solution of perchloride of iron, of a certain definite strength, is poured over the film, which solution penetrates those parts unacted on by light, reaching the steel plate, and biting itself in, but is repelled by that portion of the gelatine rendered insoluble; the plate being thus protected from the action of the solvent. Because a dilute solution of perchloride of iron soaks into a film of gelatine more readily than a strong solution, it is very important that the etching fluid should possess that amount of dilution which has been found by practice to yield the best results.

PHOTOMETER (Gr. *phos*, light; *metron*, measure), an instrument for measuring the intensity of light. The first who occupied himself in scientifically determining the intensity of light was Bouguer, but his investigations were far surpassed by those of Lambert, about 1760. The latter indicated an exceedingly simple and effective kind of photometer, which was afterwards constructed by Rumford. The instrument consists of a screen of thin paper placed vertically, and behind it, at the distance of a few inches, is placed a cylindrical stick, or any other similar body. When the intensity of light from two flames is to be compared, they are placed behind this stick in such a way that each casts a separate shadow of the stick upon the paper screen. The observer stands in front of the screen, and directs the removal of the two lights either to or from the stick, till the shadows which are cast upon the screen are equally obscure. The distance of each light from the shadow it casts on the screen is then measured; and the squares of these distances give the relative intensities of the two lights.

This photometer may also be modified by employing, instead of a cylindrical stick, a second screen parallel to the first, but of greater thickness, and having an aperture cut in its center. The two lights being then placed behind the second screen, and considerably apart, each casts a separate illumination through the aperture in the second upon the first screen, and the observer in front of the latter changes their relative distances till the illuminations appear to the eye of equal intensity. The calculation is the same as before. There are several other classes of photometers, which, however, do not deserve the name, as they depend upon the heating and chemical powers which generally accompany light, and not upon the intensity of its action on the organs of vision. Thus, Leslie's instrument is nothing more than a differential thermometer, while Saussure's and Landriani's depend upon the chemical effects of light. The chemical photometer of Bunsen and Roscoe depends on the quantity of hydrochloric acid formed in a given time from the union of its gaseous elements under the influence of light. The Bunsen photometer, of which a modified form is commonly used in gasworks, is independent of chemistry, and consists mainly of a screen of thin writing-paper on a frame, with a spot of grease on it. When there are lights on either side of the screen, the spot will show dark on the side towards the weaker light. When the lights are equal, the spot is of the same shade as the surrounding paper, and the intensity of the light is calculated from their varying distance from the screen, the square of the distance showing the power of the lights. In the well-known photometer of Bouguer, as modified by Ritchie, the lights from the two sources in comparison are reflected so as to show side by side. The more powerful is moved away till the two reflections seem equal; then the calculation from distance is made as before. Very excellent work in celestial photometry has been done of late; in the observations recently made at Harvard Observatory, many very delicate photometers, some of them new in principle, were successfully employed. (See *Nature*, 1879.)

PHOTOPHONE is the name of a comparatively simple apparatus which may be said to achieve the feat of transmitting articulate speech to a distance along a beam of light. It was first described in 1880 by Professor Graham Bell, known in connection

with the telephone, at the Boston meeting of the American Association; but already in 1878 its inventor had announced the possibility of 'hearing a shadow' by means of a similar agency. The success of the photophone depends on the peculiarities of the metal selenium. Crystalline selenium offers a high degree of resistance to the passage of an electric current; it is eminently sensitive to light; and the resistance is less when exposed to light than in the dark, being in some cases only a fifteenth in the light of what it is in the dark.

Founding on these peculiarities, Professor Graham Bell, his friends and assistants, devised some fifty forms of apparatus for so varying the transmission of light to prepared selenium as to produce audible sound. In the photophone found most serviceable, the transmitter is a plane mirror of silvered microscope glass or thin mica; the receiver, fixed at a distance without any connection, is a parabolic reflecting mirror, in the focus of which is placed a sensitive selenium 'cell,' connected in local circuit with a battery and telephone. When the apparatus is used, a strong beam of light is concentrated by a lens in the plane mirror; the speaker directs his voice against the back of this mirror, which is thrown into vibrations corresponding with those of the voice. The reflected beam of light, to which similar vibrations are also communicated, is directed through a lens to the receiving mirror, and creates in the selenium cell a rapidly intermittent current, which at the end of the telephone attached becomes audible again as vocal sound. When first described, the photophone had been used effectively with a distance of 230 yards (over a furlong) between transmitter and receiver. The rays of the oxyhydrogen light, or of an ordinary kerosene lamp, suffice for transmitting articulate speech. The loudest sounds obtained from the photophone were produced by means of a perforated disc, noiselessly revolving so as rapidly to interrupt the light in transmission.

It was also found that a very audible sound could be procured from the selenium without the aid of telephone and battery. A beam of intermittent light will produce a strong musical note from the selenium. Further experiment showed that selenium is not the only substance thus sensitive to light. Still louder sounds than these obtained from the selenium directly, though not articulate, were got from diaphragms of hard india-rubber and of antimony; and sounds of varying intensity were given out by many other substances, including gold, silver, platinum, copper, zinc, lead, paper, parchment, and wood.

PHOTO-SCULPTURE, invented by M. Willème in 1867, is an ingenious use of photography to assist a sculptor in modelling portrait statues, or fac-similes and reduced reproductions of other statues. The subject stands in the center of a circular chamber, and is simultaneously photographed by no less than twenty-four cameras, arranged at equal distances round the chamber. The twenty-four photographs are subsequently made available in the sculptor's studio, where the clay model is arranged on a frame capable of being turned round. A magic lantern throws the outline of photograph No. 1 on a screen in front of the artist, who by means of a pantograph brings this outline to bear on the clay in its first position. The model is then turned round $\frac{1}{24}$ th of a revolution, and the outline of photograph No. 2 is taken advantage of. Thus the modeller works his way, in twenty-four changes, round the model, and the likeness or fac-simile or reduced figure of the original is or should be complete. The method, which was also applied to the taking of medallions and the like, never came much into use, in spite of its ingenuity.

PHRAGMITES. See REED.

PHRASE, the name given, in Music, to the simple motives containing in themselves no satisfactory musical idea, which enter into the composition of every melody containing a perfect musical

idea, e. g.,  The phrase most usually consists of two measures; in compound time, it may be comprised in one measure, and an extended phrase is one which contains three measures. In the more simple and regular forms of musical composition, two phrases unite to form a section ending in a cadence; and a perfect musical idea is formed of two such sections terminating, the first with the dominant, the second with the tonic harmony.

1st Phrase. 2d Phrase.

Dominant Section.

1st Phrase. 2d Phrase.

Tonic Section.

A little confusion has arisen from the use, by some musical writers, of the word phrase for what is here called a section.

PHRENI'TIS. See MENINGITIS.

PHRENO'LOGY is a Greek compound signifying a discourse on the mind, but is used in a more limited sense to mean a theory of mental philosophy founded on the observation and discovery of the functions of the brain, in so far as it is concerned in intellectual and emotional phenomena. Phrenology takes into view likewise the influence of all other parts of the body, and of external agents affecting these, upon the brain.

The founder of this system was Dr. Franz Joseph Gall (q. v.), who died in 1828. In Britain it has been amply expounded by his pupil Dr. Spurzheim (q. v.), by George and Andrew Combe (q. v.), by Dr. Elliotson of London, and others. In America, Dr. Charles Caldwell has been its ablest advocate. Gall's method of investigating the functions of the brain is that which, applied to other organs, has led to the discovery of their functions, but which had never before been systematically applied to the brain. When a physiologist wished to ascertain the function of any part of the body, he did not rest satisfied with examining its structure, and speculating on the purposes for which that structure seemed to be adapted. He observed what kind of function appeared during life as the invariable accompaniment of the presence and action of that particular part; and, by repeated and careful observation, he at last succeeded in discovering the function. The knowledge thus obtained was afterwards verified and completed by examination of the structure, and observation of the effects of its injury or diseases. To the adoption of this principle in studying the functions of the brain, Gall was led by observing at school the concomitance of a quick and retentive memory of words with a peculiar appearance of the eye, which he afterwards found to be caused by a large development of a particular part of the brain. At school, at college, and in many other places, and under the most different circumstances, the same concomitance of talent with development of brain came under his notice so frequently, as to suggest to him the probability that there might be discovered by the same method a connection of other talents and dispositions with other portions of the brain. It was by the diligent application of the method of inquiry which accident had thus suggested to him, and not, as some suppose, by the exercise of his imagination, that Dr. Gall was at last led to conclude, first, that the brain is an aggregate of many different parts, each serving for the manifestation of a particular mental faculty; and, secondly, that, *all other conditions being equal*, the size of each of these cerebral organs is a measure of the power of its function. These two propositions constitute the distinctive or fundamental principles of Phrenology. The first of them, however, is not new.

The impossibility of reconciling actual phenomena with the notion of a single organ of the mind has, for many centuries, suggested the probability of a plurality of organs in the brain. But the phrenologists hold that Dr. Gall was the first to *demonstrate* the fact, and to make any considerable progress in determining with what parts of the brain the various intellectual and emotional faculties and susceptibilities are connected.

That man, in his present state, cannot think, will, or feel without the intervention of the brain, is generally admitted by physiologists, and appears from even the fact that, by pressure applied to it, consciousness is at once suspended. That it is not a single organ is *à priori* probable from such considerations as these: 1. It is a law in physiology that different functions are never performed by the same organ. The stomach, liver, heart, eyes, ears, have each a separate duty. Different nerves are necessary to motion and feeling, and there is no example of confusion amongst them. 2. The mental powers do not all come at once, as they would were the brain one organ. They appear successively, and the brain undergoes a corresponding change. 3. Genius varies in different individuals: one has a *turn*, as it is called, for one thing, and another for something different. 4. Dreaming is explained by the doctrine of distinct organs which can act or rest alone. 5. Partial insanity, or madness on one point with sanity on every other, similarly points to a plurality of cerebral organs. 6. Partial injuries of the brain, affecting the mental manifestations of the injured parts, but leaving the other faculties sound, tend to the same conclusion. 7. There could be no such state of mind

as the familiar one where our feelings contend with each other, if the brain were one organ.

These are grounds for presuming that the brain is not single but a *cluster of organs*, or at least that it is capable of acting in parts as well as in whole. For this conclusion the phrenologists consider that they have found satisfactory proofs in numerous observations, showing that particular manifestations of mind are proportioned, in intensity and frequency of recurrence, to the size of expansion of particular parts of the brain—this law being subject to modification in the case of the brain, as in that of the muscles and other parts of the body, by differences of health, quality, exercise, &c.

If size of organ, *ceteris paribus*, is the measure of the vigor of function, it is of great moment in what region of the brain the organs are largest—whether in the animal, moral, or intellectual. On this preponderance depends the character. Two brains may be exactly alike in size generally, yet the characters may be perfect contrasts to each other.

It is held by phrenologists—1. That by accurate observation of human actions, it is possible to discover the strength of the dispositions and intellectual powers of men; 2. That the form of the brain can, in normal subjects not beyond middle age, be ascertained with sufficient accuracy from the external form of the head—the brain, though the softer substance, being what determines the shape of the skull; 3. That the organs or parts of which the brain is composed appear on its surface in folds or convolutions, which have a well-ascertained fibrous connection with the *medulla oblongata*, which unites the brain to the spinal cord; 4. That the brain being divided into two equal parts called *hemispheres*, in each of which the same organ occurs, all the organs are double, like the ears and eyes. See **BRAIN**. But when the term *organ* is used, both organs are meant.

It is true that where strength is most needful, the skull is thicker than at other places; but this is not overlooked by phrenologists, nor do they fail to warn observers against mistaking for signs of cerebral development the bony processes and ridges which serve for the attachment of muscles to the skull. See **SKULL**. They recognize also, as we shall see, the uncertainty often occasioned by the frontal sinus.

Besides the brain proper, there is a smaller brain, lying below the hinder part of the main brain, and called the *cerebellum*.

The brain is divided into the *anterior*, *middle*, and *posterior lobes*. The anterior lobe contains the organs of the intellectual faculties; the posterior lobe and lower range of the middle one are the regions of the animal propensities; while the moral sentiments are stated to have their organs developed on the top or coronal region of the head.

Phrenologists distinguish between *power* and *activity* in the mental faculties. Power, in whatever degree possessed, is *capability* of feeling, perceiving, or thinking; while activity is readiness and quickness in the exercise of power.

The powers of mind, as manifested by the organs, are called *faculties*. A faculty may be defined to be a particular power of thinking or feeling. A faculty is regarded as elementary or primary—1. When it exists in one kind of animal, and not in another; 2. When it varies in the two sexes of the same species; 3. When it is not in proportion to the other faculties of the same individual; 4. When it appears earlier or later in life than the other faculties; 5. When it may act or repose singly; 6. When it is propagated from parent to child; and 7. When it may singly preserve its soundness, or singly become deranged or extinct.

The faculties are usually divided by phrenologists into two orders—**FEELINGS AND INTELLECT**, or **AFFECTIVE AND INTELLECTUAL FACULTIES**. The feelings are divided into two genera—the *Propensities* and the *Sentiments*; while the Intellectual embrace the *Perceptive* or *Knowing*, and the *Reflective Faculties*. This classification, however, is avowedly imperfect.

The following is a representation of the human head in four points of view, showing the positions of the cerebral organs, according to Mr. Combe:

AFFECTIVE.

I.—PROPENSITIES.

1. Amativeness.
2. Philoprogenitiveness.
3. Inhabitiveness or Concentrativeness.
4. Adhesiveness.
5. Combativeness.
6. Destructiveness.
[Alimentiveness.]
[Love of Life.]
7. Secretiveness.
8. Acquisitiveness.
9. Constructiveness.

II.—SENTIMENTS.

10. Self-esteem.
11. Love of Approbation.
12. Cautiousness.
13. Benevolence.
14. Veneration.
15. Firmness.
16. Conscientiousness.
17. Hope.
18. Wonder.
19. Ideality.
20. Wit, or Ludicrousness.
21. Imitation.

INTELLECTUAL.

I.—PERCEPTIVE.

22. Individuality.
23. Form.
24. Size.
25. Weight.
26. Coloring.
27. Locality.
28. Number.

29. Order.
30. Eventuality.
31. Time.
32. Tune.
33. Language.

II.—REFLECTIVE.

34. Comparison.
35. Causality.

1. *Amativeness*, or sexual love, is believed to have for its organ the cerebellum, or at least a portion of it. As the basis of domestic life, this faculty is of great importance, and its regulation has ever been one of the prime objects of moralists and legislators.

2. *Philoprogenitiveness*, or love of offspring, is generally strongest in the female. Its organ is one of the easiest to distinguish in the human head. Those who are flat and perpendicular there, instead of being delighted, are annoyed by children. The feeling is said to give a tender sympathy with weakness and helplessness in general. The most savage races must have affection for their young, or they would become extinct. The organ, like the other cerebral parts, may become diseased; and insanity on the subject of children often occurs.

3. *Inhabitiveness* (called by Mr. Combe *Concentrativeness*) has its organ immediately above the preceding. Dr. Gall did not discover its function; and Dr. Spurzheim, observing it large in persons attached to their native place, or any place in which they had long dwelt, called it *Inhabitiveness*. Mr. Combe thought it has a more extended sphere of action. He observed it large in those who can detain continuously their feelings and ideas in their minds; while the feelings and ideas of others pass away like the images in a mirror, so that they are incapable of taking systematic views of a subject, or *concentrating* their powers to bear on one point. The organ is stated as only probable, till further facts are obtained.

4. *Adhesiveness*.—The organ of this feeling was discovered by Gall, from being found very large in a lady remarkable for the warmth and steadiness of her friendships. It attaches men and gregarious animals to each other, and is the foundation of that pleasure which mankind feel in bestowing and receiving friendship, and in associating with each other. Acting with *Amativeness*, it gives constancy and duration to the attachment of the married. Generally speaking, *Adhesiveness* is strongest and its organ largest in woman.

5. *Combativeness*.—Dr. Gall discovered the organ of this propensity by a vast number of observations on the heads of persons fond of fighting. Dr. Spurzheim extended its function to *contention* in general, whether physical or moral. Those deficient in it show that over-gentle and indolent character which yields to aggression, is easily repelled by the appearance of difficulty and trouble, and naturally seeks the shades and eddy-corners of life.

6. *Destructiveness*.—The propensity to destroy is abundantly manifested by man and carnivorous animals, and when too strong or ill-regulated is the source of cruelty and wanton mischief. As a defensive power, it is of high utility. Anger, resentment, and indignation spring from it. A small endowment is one of the elements of a 'soft' character; while persons who have much

of it are generally marked by an energetic, and probably fierce and passionate character.

Alimentiveness and Love of Life.—Some of the recent phrenological works treat in this part of the order of the faculties, of a faculty of Alimentiveness, or the propensity to eat and drink, and also of another which follows—viz., Love of Life. The first being represented as no more than *probable*, and the second as only *conjectural*, they have no number allotted to them on the bust. The place assigned to Alimentiveness is marked by a cross on the side-view of the bust. Mr. Combe suggests that the organ of the Love of Life is probably a convolution at the base of the middle lobe of the brain, the size of which cannot be ascertained during life.

7. **Secretiveness** is the propensity to conceal, which in excess assumes the form of cunning. It helps animals both to avoid and to prey upon each other. In abuse, it leads to lying, hypocrisy, and fraud, and with Acquisitiveness disposes to theft and swindling. The organ is subject to disease, and cunning madmen are difficult to deal with. Disease here often leads to belief in plots and conspiracies formed against the patient.

8. **Acquisitiveness.**—The existence of a cerebral organ for the desire of property is held by phrenologists to prove that this is not, as many have thought, a derived or secondary tendency. It is what Lord Kames calls the 'hoarding appetite.' This explains the miser's desire to accumulate money, without regard to its use in the purchase of other enjoyment. When the organ is diseased, persons in easy circumstances are sometimes prone to pilfer everything of value, and often of no value, which comes in their way.

9. **Constructiveness** is the impulse to fashion and construct by changing the forms of matter. Many of the inferior animals possess it, as the beaver, bee, and birds. Physical nature consists of raw materials which Constructiveness prompts and enables man to adapt to his purposes.

10. **Self-esteem** is the source of that self-complacency which enhances the pleasure of life, gives the individual confidence in his own powers, and enables him to apply them to the best advantage. It is sometimes called proper pride, or self-respect, in which form it aids the moral sentiments in resisting temptations to meanness and vice. Its deficiency renders a man too humble, and the world takes him at his word, and push him aside. Its excess produces arrogance, selfishness, disobedience, and tyranny. Self-esteem becomes insane perhaps more frequently than any other faculty, and then shows itself in extravagant notions of self-importance. Such maniacs fancy themselves kings, emperors, and even the Supreme Being. The organ is generally larger in men than in women; and more men are insane from pride than women.

11. **Love of Approbation** is the desire of the good opinion, admiration, and praise of others. It is an excellent guard upon morals as well as manners. The loss of character, to those largely endowed with it, is worse than death. If the moral sentiments be strong, the desire will be for honest fame; but in meaner characters, the love of glory is a passion that has deluged the world with blood in all ages. Shamelessness is the effect of its deficiency, often observed in criminals. The organ oftener becomes diseased in women than in men, as in women it is more active than in the other sex generally.

12. **Cautiousness.**—The organ of this faculty is found large in persons much troubled with fears, hesitations, and doubts. Its normal character is well expressed by its name. When diseased, as it often is, the organ produces causeless dread of evil, despondency, and often suicide.

13. **Benevolence** is the desire to increase the happiness and lessen the misery of others. When strong, it prompts to active, laborious, and continued exertions, and, unless Acquisitiveness be powerful, to liberal giving to promote its favorite object. Unregulated by Conscientiousness and Intellect, Benevolence degenerates into profusion and facility. It often coexists with Destructiveness in great force; as it did in Burns, whose poem on a Wounded Hare expresses both feelings highly excited.

14. **Veneration** has for its object *whoever and whatever is deemed venerable* by the individual. One man venerates what another treats with indifference, because his understanding leads him to consider that particular object as venerable, while his neighbor deems it otherwise. But any man with a large endowment of the organ will have a tendency to consider others as superior to himself. Veneration is the basis of loyalty, and, having the Deity for its highest object, forms an element in religious feeling. So liable is its organ to disease, that high devotional excitement is one of the most common forms of insanity.

15. **Firmness** is the source of fortitude, constancy, perseverance, and determination; when too powerful, it produces obstinacy, stubbornness, and infatuation. The want of it is a great defect in character. The English soldier is more persistent than the French, although in courage and spirit they are equal.

16. **Conscientiousness** gives the love of justice, but intellect is necessary to show on which side justice lies. The judge must hear

both sides before deciding, and his very wish to be just will prompt him to do so. Conscientiousness not only curbs our faculties when too powerful, but stimulates those that are too weak, and incites us to duty even against strong inclinations. The existence of Conscientiousness as an independent element in the human constitution, explains some apparent inconsistencies in human conduct—that a man, for instance is kind, forgiving, even devout, and yet not just. The organ is commonly larger in Europeans than in Asiatics and Africans; very generally, it is deficient in the savage brain. When it is diseased, the insanity consists in morbid self-reproach, belief in imaginary debts, and the like.

17. **Hope** was regarded as a primary faculty by Spurzheim, but was never admitted by Gall, who considered it as a function of every faculty that *desires*. Dr. Spurzheim answered, that we desire much of which we have no hope. It produces gaiety and cheerfulness, looks on the sunny side of everything, and paints the future with bright colors. When not well regulated, Hope leads to rash speculation, and, in combination with Acquisitiveness, to gambling, both at the gambling-table and in the counting-house. It tends to make the individual credulous of promised good, and often indolent.

18. **Wonder.**—Dr. Gall found the organ of this faculty large in seers of visions and dreamers of dreams, and in those who love to dwell on the marvelous, and easily believe in it. Persons who have it powerful are fond of news, especially if striking and wonderful, and are always expressing astonishment; their reading is much in the region of the marvelous, tales of wonder, of enchanters, ghosts, and witches. When the sentiment is excessive or diseased, it produces that peculiar fanaticism which attempts miracles, and (with Language active) speaks in unknown tongues.

19. **Ideality.**—The organ of this faculty was observed by Dr. Gall to be prominent in the busts and portraits of deceased, and in the heads of a great number of living, poets. This confirmed to him the old classical adage, that the poet is born, not made. He called it the organ of Poetry. The name of Ideality was given to it by Dr. Spurzheim. This faculty is said to delight in the perfect, the exquisite, the *beau-ideal*, the beautiful and sublime. The organ is usually small in criminals and other coarse and brutal characters, for it is essential to refinement. It prompts to elegance and ornament in dress and furniture, and gives a taste for poetry, painting, statuary, and architecture. A point of interrogation is placed on the bust on the back part of the region of this organ, conjectured to be a different organ, but one allied to Ideality. The existence of the faculty of Ideality is held by phrenologists to prove that the sentiment of beauty is an original emotion of the mind, and to settle the controversy on that subject. See **ÆSTHETICS**.

20. **Wit, or the Sentiment of the Ludicrous.**—The phrenological writers have discussed at great length, and with not a little controversy, the metaphysical nature or analysis of this faculty. We need not follow them into this inquiry, as most of them are agreed that by means of it we feel and enjoy the *ludicrous*.

21. **Imitation.**—Dr. Gall found the prominence of this organ accompanied by instinctive, and often irrepressible mimicry. The tendency to imitate is evidently innate; from the earliest years, it makes the young follow the customs and the manner of speech of those around them, and so preserves a convenient uniformity in the manners and externals of society. Celebrated actors always possess it strong, and by its means imitate the supposed manner, and even feel the sentiments, of their characters. Its organ is found large also in painters and sculptors of eminence. In its morbid states, the impulse to mimic becomes irresistible.

We now come to the Intellectual Faculties, or those which make us acquainted with things that exist, and with their qualities and relations. Dr. Spurzheim divided them into three genera—1. The External Senses; 2. The Internal Senses, or Perceptive Faculties; 3. The Reflecting Faculties.

The external senses, as generally received, are five in number—Touch, Taste, Smell, Hearing and Sight. There seem to be two more—namely, the *Sense of Hunger and Thirst*, and the *Muscular Sense*, or that by which we feel the state of our muscles as acted upon by force and resistance. Without this last sense, we could not keep our balance, or suit our movements to the laws of the mechanical world. Whether each sense has a special cerebral organ in addition to its external apparatus and nerves, is a question regarded by phrenologists as still undetermined.

22. **Individuality**, the first in the list of the perceptive faculties, is not easily defined. It is said to take cognizance of individual objects as such, e. g., a horse or a tree. Other knowing faculties perceive the form, color, size, and weight of the horse, but Individuality is thought to unite all these, and give the idea of a horse. It is regarded as the storehouse of knowledge of things simply *existing*. When it is strong, without being accompanied by reflecting power, the mind is full of facts, but unable to reason from them. After puberty, the size of the organ of Individuality, as well as of the neighboring organs of Size, Weight, Coloring, and

Locality—all situated behind the superciliary ridge of the skull—is often rendered doubtful by the existence of a hollow space, of uncertain width and extent between the two plates of the skull. This hollow is called the *frontal sinus*; and when it is large, there may be a great projection of the bone over the eyes, without a corresponding projection of brain within. When this part of the skull is flat, however, the organs must be at least as defective as the flatness indicates. Owing to the source of uncertainty here pointed out, and the smallness of the organs behind the eyebrows, the functions of those parts of the brain are not regarded as being so well ascertained as those of the larger organs, nor will a cautious phrenologist be too ready to pronounce them large.

23. Form.—When the organ of Form is large, the eyes are wide asunder. Dr. Gall discovered it in persons remarkable for recognizing faces after long intervals, and although perhaps only once and briefly seen. The celebrated Cuvier owed much of his success in comparative anatomy to his large organ of Form. Decandolle mentions that 'his [Cuvier's] memory was particularly remarkable in what related to forms, considered in the widest sense of that word; the figure of an animal seen in reality or in drawing never left his mind, and served him as a point of comparison for all similar objects.'

24. Size.—Every object has size or dimension; hence a faculty seems necessary to cognize this quality. The supposed organ is situated at the inner extremities of the eyebrows, where they turn upon the nose. A perception of size (including distance) is important to our movements and actions, and essential to our safety.

25. Weight.—A power to perceive the different degrees of weight and force is likewise essential to man's movements, safety, and even existence. Phrenologists have generally localized the organ of that power in the part of the brain marked 25 on the bust.

26. Coloring.—The organ of this faculty is large in great painters, especially great colorists, and gives an arched appearance to the eyebrow; for example, in Rubens, Titian, Rembrandt, Salvator Rosa, and Claude Lorraine. In cases of color-blindness, it is found small. Many persons, though able to distinguish colors, have no perception of their harmonies: for this perception, a higher endowment of the faculty seems to be required.

27. Locality.—Dr. Gall was led to the discovery of this faculty by comparing his own difficulties with a companion's facilities, in finding their way through the woods, where they had placed snares for birds, and marked nests, when studying natural history. Every material object must exist in some part of space, and that part of space becomes *place* in virtue of being so occupied. Objects themselves are cognized by Individuality; but their place, the direction where they lie, the way to them, fall within the sphere of Locality. Its organ is large in those who find their way easily, and vividly remember places in which they have been. It materially aids the traveler, and is supposed to give a love for traveling. The organ was large in Columbus, Cook, Park, Clarke, and other travelers.

28. Number.—The organ of this faculty is placed at the outer extremity of the eyebrows and angle of the eye. It occasions, when large, a fullness or breadth of that part of the head, and often pushes downward the external corner of the eye. When it is small, the part is flat and narrow between the eye and the temple. Dr. Gall called the faculty *le sens des rapports des nombres* (the Sense of the Relations of Numbers), and assigned to it not only arithmetic, but mathematics in general. Dr. Spurzheim more correctly limits its functions to arithmetic, algebra, and logarithms; geometry being the products of other faculties, particularly Size and Locality. Dr. Gall first observed the organ in a boy who could multiply and divide, mentally, ten or twelve by three figures in less time than expert arithmeticians could with their pencils. Many such examples are on record.

29. Order.—The organ of this faculty is said to be large in those who are remarkable for love of method, neatness, arrangement, and symmetry, and are annoyed by confusion and irregularity. In savages, whose habits are slovenly, filthy, and disgusting, the organ is comparatively small.

30. Eventuality.—The organ is situated in the very center of the forehead, and when large, gives to this part of the head a rounded promnency. Individuality has been called the faculty of *nouns*; Eventuality is the faculty of *verbs*. The first perceives merely things that exist; the other, motion, change, event, history. The most powerful *knowing* minds have a large endowment of both Individuality and Eventuality; and such persons, even with a moderate reflecting capability, are the clever men in society—the acute men of business—the ready practical lawyers. The organ of Eventuality is generally well developed in children, and their appetite for *stories* corresponds.

31. Time.—Some persons are called walking time-pieces; they can tell the hour without looking at a watch; and some even can do so, nearly, when waking in the night. The impulse to mark time is too common, too natural, and too strong, not to be the re-

sult of a faculty; it is an element in the love of dancing, almost universal in both savage and civilized man.

32. Tune.—The organ of Tune is large in great musicians; and when it is small, there is an utter incapacity to distinguish either melody or harmony. The great bulk of mankind possess it in a moderate endowment, so as to be capable of enjoying music in some degree. Those in whom it is large and active, become in all stages of society, distinguished artists, exercising a peculiar power over their fellow-creatures, so as to rouse, melt, soothe, and gratify them at pleasure. But the gift, in this active form, is liable to be much modified according as it is accompanied by Adhesiveness, Combativeness, Ideality, Benevolence, Wit, and other faculties.

33. Language.—The comparative facility with which different men clothe their thoughts in words, and learn to repeat them by heart, depends on the size of the organ of Language, which is situated on the super-orbital plate, immediately over the eyeball, and, when large, pushes the eye outwards, and sometimes downwards; producing in the latter case, a wrinkling or pursing of the lower eyelid. Verbal memory is strong or weak, without relation to the strength or weakness of the memory of things, forms, or numbers.

The Perceptive Organs are for the most part called into activity by *external* objects; but internal causes often excite them, and objects are then perceived which have no external existence, but which, nevertheless, the Individual may believe to be real. This is the explanation of visions and ghosts, and of the fact that two persons never see the same spectres at the same time. Excess or disease in the organ of Wonder predisposes to belief in the marvelous and supernatural, and probably stimulates the Perceptive organs into action, when spectral illusions are the consequence.

34. Comparison.—Dr. Gall discovered the organ of this faculty in a man of science who reasoned chiefly by means of analogies and comparisons, and rarely by logical deductions. The middle of the upper part of his forehead was very prominent. The precise nature of the faculty has been much disputed among the Phrenologists, but they seem to agree that the perception of analogy depends upon it. Every faculty, we are told, can compare its own objects: Coloring can compare colors; Weight, weights; Form, forms; Tune, sounds; but Comparison can compare a color with a note, or a form with a weight, &c. Analogy is a comparison not of things, but of their relations.

35. Causality.—This is regarded as the highest and noblest of the intellectual powers. Dr. Spurzheim so named it from believing that it traces the connection between *cause* and *effect*, and recognizes the relation of ideas to each other in respect of *necessary consequence*. Some metaphysicians have held that we have no idea of cause, but see only sequence, or one event following another. See CAUSE. It is true that we do see sequence; but we have a *third* idea—that of power, agency, or efficiency, existing in some way in the antecedent, to produce the consequent. Whence do we get this third idea?—from a distinct faculty, Causality. It is a large ingredient in wisdom.

The phrenologists have chiefly confined their attention to the organs of the brain, and the various faculties of which these are the instruments. The former writers on mind—Reid, Stewart, Brown, and others—gave, on the contrary, their chief care to the mental acts called Attention, Perception, Conception, &c., which they considered as faculties. The phrenologist does not overlook the importance of this department of mental philosophy, but differs from the metaphysicians in considering perception, conception, memory, &c., as only *modes* in which the real faculties above described act. This distinction is one of great importance.

According to the phrenologists, the faculties are not mere passive susceptibilities; they all tend to action. When duly active, the actions they produce are proper or necessary; in excess or abuse, they are improper, vicious, or criminal. Small moral organs do not produce abuses; but they are unable to prevent the abuse of the animal organs, as larger tend to do; thus small Benevolence is not cruel, but it does not offer sufficient control to Destructiveness, which then impels to cruelty. *Cateria paribus*, large organs have the greatest, and small the least tendency to act—each faculty producing the feeling or idea peculiar to itself. In active constitutions, the brain partakes of the general activity, and comes more readily into play than where the constitution or temperament is lymphatic. Health and disease, exercise and inaction, nutrition and starvation, have also great influence in modifying both the power of the cerebral organs and their readiness to act. Moreover, when certain faculties have been much exercised for a series of generations in a family, they are apt to be manifested in greater strength and activity than where no such hereditary influence exists. Seeing that all the organs tend to action, each, it is concluded, must have a legitimate sphere of action, and be necessary for the welfare of man.

The PROPENSITIES and SENTIMENTS cannot be called into action by the will. We cannot fear, or pity, or love, or be angry, by willing it. But *internal* causes may stimulate the or-

gans, and then, whether we will or not, their emotions will be felt. Again, these feelings are called into action in spite of the will, by the presentation of their *external* objects—Cautiousness, by objects of terror; Love, by beauty, and so on. The excitability of the feelings, whether stimulated from within or without, is increased by activity of the temperament. Insanity is a frequent result of over-activity of the propensities and sentiments. These may be diseased and yet the intellect sound. The converse is also true. When an organ is small, its feeling cannot be adequately experienced. The will can *indirectly* excite the propensities and sentiments by setting the intellect to work to find externally, or conceive internally, the proper objects. Lastly, these faculties do not form ideas, but simply feel; and therefore have no memory, conception, or imagination.

The PERCEPTIVE and REFLECTING FACULTIES, or Intellect, form ideas, perceive relations, and are subject to, or rather constitute, the Will; and minister to the affective faculties. They may be excited by external objects and by internal causes. When excited by the presentation of external objects, these objects are *perceived*, and this *act* is called PERCEPTION. It is the lowest degree of activity of the intellectual faculties; and those who are deficient in a faculty cannot perceive its object.—CONCEPTION also is a mode of action of the faculties, not a faculty itself. It is the activity of the faculties from internal causes, either willed, or involuntary from natural activity.—IMAGINATION is Conception carried to a high pitch of vivacity.—MEMORY, too, is not a faculty, but a mode of action. There is no such thing as the *general* memory of the metaphysicians, but every intellectual faculty has its own memory. Memory differs from Conception and Imagination in this, that it recalls *real* objects or events which it has actually perceived, and adds the consciousness of time elapsed since they were perceived. The other named modes of action do not require realities or time.—JUDGMENT is, properly, the perception of adaption, fitness, and necessary consequence; this is a mode of action of the reflecting powers. In a certain sense, the Perceptive Faculties may each be said to possess judgment; as Coloring judges of colors; Form, of forms; Tune, of music. By the word 'judgment,' however, is meant right reasoning, sound deciding. To this, a proper balance of the affective faculties is essential. There can be no sound judgment where any of the feelings are excessive.—CONSCIOUSNESS is the knowledge which the mind has of its own existence and operations.—ATTENTION is not a faculty, but the application, or *tension*, of any or all of the intellectual faculties.—ASSOCIATION is the succession of ideas in the mind, each seeming to call up that which succeeds; so that in our waking-hours the mind is never without an idea passing through it. This is a state or condition of the faculties, not a faculty.—PASSION is any faculty in excess; Love is the passion of Amativeness in union with Adhesiveness and Veneration; Avarice, of Acquisitiveness; Rage, of Destructiveness.—PLEASURE and PAIN, JOY and GRIEF, also belong to each faculty, according as it is agreeably or disagreeably affected.—HABIT is the power of doing anything well, acquired by frequently doing it. But before it can be done at all, there must be the faculty to do it, however awkwardly.—TASTE was held by Mr. Stewart to be a faculty, and to be acquired by habit. It seems to be the result of a harmonious action of all the faculties.

Such is an outline of the system propounded by the phrenologists. So far as it shall be confirmed by the mature experience and observation of competent inquirers, the facts and principles which it unfolds must be of great practical value to mankind. The study of the mutual influence of the mind and body has ever been recognized by wise and observant men as one of high importance, though of great difficulty; and certainly, Gall and his followers have not only given a strong impulse to that study, but have thrown much light on the diversities of human character, and accumulated a large body of facts of a kind which had previously been too much overlooked. Much, it is admitted, still remains to be discovered. 'No phrenologist,' says Mr. Combe, 'pretends that Gall's discoveries are perfect; they are far from it, even as augmented and elucidated by his followers; but I am humbly of opinion that, in their great outlines, his doctrines are correct representations of natural facts. . . . The future of phrenology will probably exhibit a slow and gradual progress of the opinion that it is true and important; and only after this stage shall have been passed, will it be seriously studied as science. Hitherto this has not been done: the number of those who have bestowed on it such an extent of accurate and varied observation and earnest reflection as is indispensable to acquiring a scientific knowledge of chemistry, anatomy, natural philosophy, or any other science, is extremely small; and the real knowledge of it, on the part of such as continue, through the press and in public lectures, to oppose it, appears to me scarcely greater than it was in 1815 and 1826,' when it was ridiculed in the *Edinburgh Review*.

In considering the claims of phrenology, two questions should not be confounded. One is—How far the functions of the differ-

ent parts of the brain have been established by observation of extreme instances of their large and small development?—the other, To what extent the facts so ascertained can be applied physiologically in practice? Gall disclaimed the ability to distinguish either ill-defined modifications of forms of the skull, or the slighter shades of human character (*Sur les Fonctions du Cerveau*, iii. 41); nor, we believe, did he or Spurzheim ever pretend to estimate the size of *every* organ in a single brain. By attempting too much in these directions some of their disciples may have helped to prolong the incredulity with which phrenology is still widely regarded.

For the titles of numerous books on phrenology, see GALL (F. J.), Spurzheim (J. G.), and COMBE (G.); also an article in *The British and Foreign Medical Review*, vol. ix. p. 190. Of other important works bearing on, or criticising phrenology, we may mention Dr. Laycock's *Mind and Brain, or the Correlation of Consciousness and Organization* (2 vols. Edin. 1860); his article on Phrenology in the 8th ed. of the *Encyc. Brit.*; an article on Phrenological Ethics in the *Edinburgh Review* for January 1842, vol. lxxiv. p. 376; Aug. Comte's *Philosophie Positive*, tom. iii. (or Miss Martineau's transl., i. 466); Sir Benj. C. Brodie's *Psychological Inquiries*, Dialogue vi. (Lond. 1854); G. H. Lewes's *Biog. Hist. of Philos.*, p. 629 (Lond. 1857); Samuel Bailey's *Letters on the Philosophy of the Human Mind*, 2d Series, Letters xvi.—xxi. (Lond. 1858); and Professor Bain's *On the Study of Character, including an Estimate of Phrenology* (Lond. 1861). Sir William Hamilton's objections, mostly published many years since, and which are now appended to his *Lectures on Metaphysics*, i. 404 (Edin. 1859), were discussed in the *Phren. Jour.*, vols. iv. and v., and are remarked on by Mr. Combe in his work *On the Relation between Science and Religion*, pref., p. xvii. (Edin. 1857).

PHRYGIA'NEA. See CADDICE.

PHRY'GIA, a country in Asia Minor, the extent and boundaries of which varied very much at different periods of ancient history. In pre-historic ages it is believed to have comprised the greater part of the peninsula, but at the time of the Persian invasion it was limited to the districts known as Lesser Phrygia and Greater Phrygia—the former stretching from the Hellespont to Troas (inclusive), the latter occupying a central portion of Asia Minor. The inland boundaries of Lesser Phrygia are not well ascertained; but Greater Phrygia was bounded on the N. by Bithynia and Paphlagonia, on the E. by Cappadocia and Lycaonia, on the S. by the Taurus range, and on the W. by the maritime countries of Mysia, Lydia, and Caria. At a later period it was considerably reduced by the formation of Galatia (q. v.) and the extension of Lycaonia. P. was in general a high and somewhat barren plateau, though its pastures supported immense flocks of sheep, noted for the fineness of their wool, as indeed they still are. The most fertile part was the valley of the Sangarius, but the most beautiful and populous district was the southwest, at the base of the Taurus, where the Mæander and other streams had their rise. The mountains and streams yielded gold; Phrygian marble was anciently celebrated, and the cultivation of the vine appears to have been extensively carried on.

The origin of the Phrygians is one of the mysteries of ancient ethnology. Some think that they were settled at a very remote period in Europe, and that they emigrated from Thrace into Asia Minor; and Xanthus, Herodotus, and Strabo certainly speak of such a migration. Xanthus places it after the Trojan war; but if there be any truth in the tradition at all, it can only refer to a return of some tribes to the cradle of the race in the valley of the Sangarius, for the Phrygians were regarded as one of the oldest races (if not the very oldest) in Asia Minor.

Instead of seeking for their origin in Thrace, the best classical ethnologists seek for it in the neighboring highlands of Armenia, whence the Phrygians are believed to have spread at the period far before the dawn of authentic history over the greater part of the Peninsula, and thence to have crossed into Europe, and occupied the greater part of Thrace, Macedonia, and Illyria; while the mythic Pelops, who colonized the Peloponnesus, and gave it his name, was said by tradition to be a Phrygian. In both Greek and Latin poetry the Trojans are also called Phrygians, and the same name is applied to other nations of Asia Minor, such as the Mydonians and Mysians. In Thrace, too, many of the names of places were the same as in Troas; while it has now been demonstrated that the Armenian, Phrygian, and Greek languages are akin to each other, so that peoples speaking the two former tongues, like those speaking the latter, belong to the great Aryan branch of the human family. The Phrygians began to decline in power and number after the Trojan war. They were—if we can make anything like historic fact out of the mythic narratives of that early time—pushed out of Europe by the Illyrians in the north and the Macedonians in the south, while in Asia Minor the rise of the Semitic Assyrians also depressed and weakened them, by breaking up the integrity of their territory. The whole of the south coast of the peninsula was occupied by Semitic invaders; the

Lydians and Cappadocians were of Syro-Phœnician origin; and Strabo speaks of structures of Semiramis as far north as Pontus. Their language, manners, and religion even, underwent radical changes—hence the great difficulty experienced in ascertaining their original characteristics. After being subjugated by Cræsus, they passed, on the dissolution of the Lydian monarchy, under the sway of Cyrus; and it is only from this date that they are brought within the pale of positive history. Their country formed part of the empire of Alexander, and subsequently belonged to the Syrian Seleucidæ, to the kings of Pergamum, and to the Romans, who obtained possession of it, 133 B.C.

The Phrygians had not a warlike reputation among the ancients, but though in later times commonly described as indolent and stupid, yet, like negroes, they were of a mystic and excitable disposition. Their religious orgies, accompanied by wild music and dancing, are frequently mentioned by classic writers, and appear to have exercised a very material influence on Hellenic worship. Cybele, 'the great mother of the gods,' was the chief Phrygian divinity; others were Sabazius (Dionysus), Olympus Hyagnis, Lityrses, and Marsyas.

PHRYNĒ, one of the most celebrated courtesans of antiquity, was the daughter of Epicles, and was born at Thespiæ in Bœotia. Her position in life was originally very humble, and she is said to have at one time earned a livelihood by gathering capers; but as the fame of her marvelous beauty spread, she obtained numerous lovers, who lavished gifts on her so profusely that she became enormously rich. In proof of this, the story goes that she offered to rebuild the walls of Thebes, if the citizens would allow her to place this inscription on them: 'Alexander destroyed them; Phryne, the courtesan, rebuilt them.' The Thebans declined the proposal. Her enemies accused her of profaning the Eleusinian mysteries. Summoned before the tribunal of the Heliasts, she was defended by the rhetorician Hyperides, one of her lovers, who, perceiving that his eloquence failed to convince the judges, threw back her veil, and displayed her naked shoulders and bosom. She was immediately acquitted, and carried in triumph to the Temple of Venus. The famous picture of Apelles (q. v.)—the 'Venus Anadyomene'—is said to have been a representation of P. Praxiteles, also a lover of hers, employed her as a model for his 'Cnidian Venus.'

PHTHI'SIS. See CONSUMPTION.

PHULOW'DI, a town of India, in the Rajpoot state of Jodhpoor, in lat. 27° 8' N. Pop. 15,000.

PHULWARA TREE, See BASSIA.

PHYLACTERY (from Gr. *phylax*, to guard), an amulet or charm worn by the Greeks against demoniac influences. Certain strips of parchment, inscribed with certain passages from the Scripture (Exodus xiii. 1–10, 11–16; Deuteronomy vi. 4–9, xi. 13–21), enclosed in small cases, and fastened to the forehead and the left arm (*Tefillin*)—also, in another form, to door-posts (*Mesusah*)

—in use with the Jews, in imagined accordance with Exodus xiii. 9–16, &c., are also called in the New Testament phylacteries. The writing of these is in the hands of privileged scribes (*Sopherim*) only, and many and scrupulous are the ordinances which they have to follow in the execution of this task. Only vellum of a very superior kind is to be used; the characters must be traced with the greatest care; no erasures or corrections are allowed; the lines and letters must be of equal length; &c. The case in which they are enclosed consists of several layers of calf-skin or parchment. It may be observed, by the way, that not the wearing, but the exaggerated form of the phylacteries worn by some of the Pharisees, is inveigled against by Christ.

Phylactery.

PHYLLOSO'MA. See GLASS-CRABS.

PHYLLOXERA (Gr. *phylon*, a leaf, and *xeros*, dry), a genus of insects of the order Hemiptera, sub-order Homoptera, the type of a family, *Phylloxeridae*, allied to the *Aphis* (q. v.) and *Coccus* (q. v.) families. The *Phylloxeridae* attach themselves to various plants, on the juice of which they feed, and which they often injure or destroy. *P. vastatrix* is the name given to an insect of this family, which, since 1865, has committed great devastation in the vineyards of France, and seems to have been imported from North America. Great numbers of this insect appear on the roots of the vine, and their puncturings are so numerous and incessant, that the roots can no longer supply nutriment to the plant, which accordingly fades and dies. The *P. vastatrix* has also been observed on the leaves of the vine. It measures, when fully grown, only about $\frac{1}{16}$ of an inch in length. It is provided with a long, slender proboscis, which lies in a groove in its under side. Yellow in summer, it becomes brown at the end of autumn. Another variety, the OAK P. (*P. quercus*), appears on the leaves of oak-trees.

PHYSA'LIA, a genus of *Aculephæ*, having an oval or oblong body, which consists in great part of an air sac, so that the creature floats on the surface of the sea, with numerous appendages of various kinds hanging from its under side. The shorter of these appendages are suckers, which are kept in constant motion for procuring prey, and which seem also to be employed in extracting nutriment from it, as the P. has no proper mouth nor alimentary canal. Among these shorter appendages, also, some seem to be devoted to the purpose of reproduction by germination. The longer appendages, which are extremely long—those of a P. five or six inches in length, being capable of extension to twelve or eighteen feet—are rope-like tentacles, possessing a remarkable stinging power, which is probably used for benumbing prey. It is a common trick with sailors to make a novice pick up a P., the beautiful colors of which always attract admiration. The stinging power is, however, such as not merely to produce local pain, but constitutional irritation.

Portuguese Man-of-War (*Physalia pelagica*).

It was at one time supposed that the P. has the power of expelling air from its bladder, and sinking at pleasure in the sea; but the observations of Mr. Bennett (*Gatherings of a Naturalist in Australia*) render it more probable that it always floats on the surface, and is driven about by the winds. The name *Portuguese Man-of-War* is often popularly given to the species of P., and particularly to *P. pelagica*. The *Physalia* inhabit the seas of warm latitudes, but shoals of them are occasionally driven to the British coast.

PHY'SALIS, a genus of plants of the natural order *Solanaceæ*, remarkable for the calyx, which becomes large and inflated after flowering is over, and incloses the ripened berry. The species are annual and perennial herbaceous plants and shrubs, natives of temperate and warm climates, and widely scattered over the world. The COMMON WINTER CHERRY (*P. alkekengi*) is a

Love Apple (*Physalis peruviana*).

perennial, native of the south of Europe and great part of Asia, growing in vineyards and bushy places. It is not a native of Britain, but is pretty frequent in flower-gardens. The berries have a sweetish subacid taste; they are seldom eaten in Britain, but very generally in many parts of the continent of Europe. They are refrigerant and diuretic, and were formerly employed in medicine on account of these properties. The DOWNY WINTER CHERRY, or PERUVIAN GOOSEBERRY (*P. pubescens* or *P. Peruviana*), is an annual American species, densely clothed with down; with heart-shaped leaves, yellow flowers, and yellowish berries, which are eatable.

PHYSE'TER. See CACHOLOT.

PHYSIC NUT (*Curcas*), a genus of plants of the natural order *Euphorbiaceæ*, having a 5-partite calyx, 5 petals, and 8–10 unequal united stamens. The species are not numerous. They are tropical shrubs or trees, having alternate, stalked, angled or lobed leaves, and corymbs of flowers on long stalks; and notable for the acrid oil of their seeds. The COMMON P. N. of the East Indies (*C. purgans*), now also common in the West Indies and other warm parts of the world, is a small tree or bush, with a milky juice. It is used for fences in many tropical countries, and serves the purpose well, being much branched and of rapid growth. The seeds are not unpleasant to the taste, but abound in a very acrid fixed oil, which makes them powerfully emetic and purgative, or in large doses poisonous. The expressed oil, commonly called *Jatropha*

Oil, is used in medicine like croton oil, although less powerful; it is also used in lamps.—The FRENCH P. N., or SPANISH P. N. (*C. multifidus*), a shrub, native of the tropical parts of America, with many-lobed leaves, yields a purgative acrid oil, called *Oil of Pinhoen*. To this genus belongs the PINONCILLO (*C. lobatus*) of Peru, the seed of which is eaten when roasted, and has an agreeable flavor, although when raw it is a violent purgative. When an incision is made in the stem of this tree, a clear bright liquid flows out, which after some time becomes black and horney. It is a very powerful caustic, and retains this property for years.

PHY'SICAL GEOGRAPHY. See GEOGRAPHY.

PHYSICIANS, THE ROYAL COLLEGE OF (of London), was founded in 1518 by the munificence of Thomas Linacre, a priest and distinguished physician, who was born in 1460, and died in 1524. In 1518, through the influence of Cardinal Wolsey, he obtained from Henry VIII. letters-patent granting to John Chamber, himself, and Ferdinandus de Victoria, the acknowledged physicians of the king, together with Nicholas Halsewell, John Francis, Robert Yaxley, and all other men of the same faculty in London, to be incorporated as one body and perpetual community or college. They were permitted to hold assemblies, and to make statutes and ordinances for the government and correction of the College, and of all who exercised the same faculty in London and within seven miles thereof, with an interdiction from practice to any individual unless previously licensed by the President and College. Linacre was the first president, and held the office till his death in 1524. The meetings of the College were held at his house in Knightbridge Street, which he bequeathed to the College, and which, until the year 1860, continued in the possession of that body. About the time of the accession of Charles I., the College, requiring more accommodation, took a house at the bottom of Amen Corner, which was subsequently purchased by Dr. Harvey, and in 1649 was given by him to his colleagues. This was the seat of the College till 1666, when it was destroyed by the great fire of London. A new College was then built in Warwick Lane, and opened in 1674 under the presidency of Harvey's friend, Sir George Ent; and here the meetings were held till 1825, when the present edifice in Pall-Mall East was opened under the presidency of Sir Henry Hallford.

The reason for forming the incorporation, as set forth in the original charter, is 'to check men who profess physic rather than avarice than in good faith, to the damage of credulous people;' and the king (following the example of other nations) founds 'a college of the learned men who practise physic in London and within seven miles, in the hope that the ignorant and rash practisers be restrained or punished.' The charter further declares, that 'no one shall exercise the faculty of physic in the said city, or within seven miles, without the College license, under a penalty of £5; that, in addition to the president, 'four censors be elected annually to have correction of physicians in London and seven miles' circuit, and of their medicines, and to punish by fine and imprisonment; and that 'the President and College be exempt from serving on juries.' Four years later, in 1523—1523, an act was passed confirming the charter, and enacting that 'the six persons before said named as principals and first-named of the said commonalty and fellowship, shall choose to them two men of the said commonalty from henceforward to be called and cleaped Elects, and that the same elects yearly choose one of them to be president of the said commonalty;' and further directing that, in case of a vacancy by death or otherwise, the surviving elects shall choose successors.

In 1540 an act was passed in which it was declared explicitly that 'surgery is a part of physic, and may be practised by any of the company or fellowship of physicians'—a doctrine which in later times has been totally repudiated by the collegiate body, who, until a few years ago, would not admit to their privileges a member of the Royal College of Surgeons, unless he formally resigned his surgical diploma. Other acts were passed in 1533, 1814, and 1858; the last known as 'the Medical Act,' providing for the granting of a new Charter to the College, which was obtained in 1862. Finally, in 1860, 'an Act to Amend the Medical Act' was passed, which repeals the provisions of the act of 1522—1523 as to the elects, and declares that the Presidency shall in future be an annual office, open to the Fellows at large, who shall also be the electing body. As at present constituted, the College consists of Fellows, Members, Licentiates, and Extra-Licentiates. The *Fellows* are elected from members of at least four years' standing, who have distinguished themselves in the practice of medicine, or in the pursuit of medical or general science or literature. The government of the College is vested in the President and Fellows only.

The present *Members* consist of persons who had been admitted, before 16th February 1859, Licentiates of the College; of extra-licentiates who have complied with certain conditions; and of persons who have attained the age of 25 years, who do not dispense or supply medicine, and who, after being duly proposed,

have satisfied the College 'touching their knowledge of medical and general science and literature,' and that they have 'been engaged in the study of physic during a period of five years, of which four years at least shall have been passed at a medical school recognized by the College.' No candidate is admissible if engaged in trade or connected with a druggist's business, or who even practises medicine in partnership with another practitioner, so long as the partnership lasts, or who refuses to publish, when required, the nature and composition of any remedy he makes use of. The *Members* are alone eligible for the Fellowship. They constitute a portion of the corporation, in so far as they have the use of the library and museum, and the privilege of admission to all lectures; but they do not take any share in the government, or attend or vote at meetings. The examiners for the membership are the president and censors. The *Licentiates* are not members of the corporation; they have access to the museum, lectures, and reading-room, but are not allowed to take books away from the library; they may compound and dispense medicines for *patients under their own care*; and in their qualifications very much resemble those who have diplomas both from the College of Surgeons and the Apothecaries' Hall. They must be 21 years of age, and must have been engaged in professional studies for four years before being admitted to examination. The fee for admission as a Fellow is 30 guineas, exclusive of stamp-duty; the Member's fee is also 30 guineas, and the Licentiate's 15 guineas.

The following bye-laws of the College should be generally known. 1. No Fellow of the College is entitled to sue for professional aid rendered by him. This bye-law does not extend to Members. 2. No Fellow, Member, or Licentiate of the College is entitled to assume the title of Doctor of Medicine unless he be a graduate in medicine of a university. 3. No Fellow or Member of the College shall officiously, or under color of a benevolent purpose, offer medical aid to, or prescribe for, any patient whom he knows to be under the care of another legally qualified medical practitioner.

PHYSICIANS OF EDINBURGH, THE ROYAL COLLEGE OF, had its rise in 1617, in an attempt to incorporate the practitioners of medicine, and raise the standard of the profession. King James I. of England looked favorably on the proposal, and granted an order for its establishment; Cromwell in like manner issued a patent in its favor, but both were frustrated by the religious dissensions of the times, and it was not until 1681 that the body became incorporated under a charter from Charles II. A new charter with many important provisions was issued in 1861. To the Physicians belongs the honor of having suggested in 1725 the plan of an Infirmary in Edinburgh for the sick poor, which has developed into the present magnificent institution. From the first they undertook its medical charge gratuitously. The Royal Edinburgh Asylum for the Insane at Morningside was also first suggested by them in 1791. The College, which in 1879 had over 160 fellows, possesses a library of upwards of fifteen thousand volumes; also a valuable and interesting Museum of Materia Medica. An important arrangement was made in 1859 between the Edinburgh College of Surgeons (q. v.) and that of the Physicians, which had long been on hostile terms, making it competent for the two to combine, in order, by a joint examination, to give a double qualification, embracing medicine and surgery.

PHYSICS, or PHYSICAL SCIENCE (Gr. *physikos*, natural), comprehends in its widest sense all that is classed under the various branches of mixed or applied mathematics, natural philosophy, chemistry, and natural history, which branches include the whole of our knowledge regarding the material universe. In its narrower sense, it is equivalent to Natural Philosophy (q. v.), which, until of late years, was the term more commonly used in Great Britain, and denotes all knowledge of the properties of bodies as bodies, or the science of phenomena unaccompanied by essential change in the objects; while chemistry is concerned with the composition of bodies, and the phenomena accompanied by essential change in the objects; and natural history, in the widest sense, includes all the phenomena of the animal, vegetable, and mineral world. The application of the term *Physic* to a branch of this last—viz., the science of medicine—is peculiar to the English language.

PHYSIOGNOMY (Gr.), the art of judging of the character from the external appearance, especially from the countenance. The art is founded upon the belief, which has long and generally prevailed, that there is an intimate connection between the features and expression of the face and the qualities and habits of the mind; and every man is conscious of instinctively drawing conclusions in this way for himself with more or less confidence, and of acting upon them to a certain extent in the affairs of life. Yet the attempt to reach this conclusion by the application of certain rules, and thus to raise the art of reading the human countenance to the dignity of a science, although often made, has never yet been very successful. Comparisons have been instituted for this purpose between the physiognomies of human beings and of

species of animals noted for the possession of peculiar qualities, as the wolf, the fox, &c. This was first begun by Della Porta, a Neapolitan, who died in 1615, and was afterwards carried further by Tischbein. The subject of physiognomy was eagerly prosecuted by Thomas Campanella; and later and more thoroughly by Lavater (q. v.).

PHYSIOGRAPHY, a term formerly used of a branch of mineralogy, was adopted by Professor Huxley as a convenient name for an exposition of the principles that underlie physical geography, and including the elements of physical science. P. is thus understood to involve a compendious discussion of gravitation, heat, the composition of the crust of the earth, the movements of the sea, the phenomena of the atmosphere, and many cognate subjects, treated in this work under separate heads.

PHYSIOLOGY (Gr. *physis*, nature; *logos*, a discourse) is the science which treats of the phenomena which normally present themselves in living beings, of the laws or principles to which they are subject, and of the causes to which they are attributable. It is therefore a branch of Biology, the science which investigates the nature and relations of living bodies. As dealing with *functions*, P. is distinguished from morphology, the branch of biology which takes cognizance of the structure of the parts or organs. According as it has to do with one or other of the two great groups of organic beings, Physiology is *Animal Physiology* or *Vegetable Physiology*. *General Physiology* includes the structure and chemical composition of bodies, though anatomy and histology precede Physiology in the order of the sciences. *Comparative Physiology* deals with the resemblances and diversities between the vital actions of various groups and species. *Special Physiology* treats of the vital phenomena of particular species, *Human Physiology* being, of course, restricted to the human subject. The functions expounded by P. are usually regarded as falling under three main heads, viz. those of (1) Nutrition; (2) Innervation; and (3) Reproduction. The principles of *Vegetable Physiology* are in this work treated under that head; the various portions of *Animal Physiology*, especially human, will generally be found discussed along with the anatomy of the organs concerned, under such heads as DIGESTION, CIRCULATION, RESPIRATION, NUTRITION; BRAIN, NERVOUS SYSTEM. SPINAL CORD, AUDITORY NERVE, EAR, NOSE, &c.; REPRODUCTION, and many others.

PHYTOLACCA, a genus of exogenous plants of the natural order *Phytolaccaceae*. This order contains about 70 known species, half-shrubby and herbaceous plants, natives of warm parts of Asia, Africa, and America, and is nearly allied to the order *Chenopodiaceae*, and to the *Polygonaceae*. The genus *Phytolacca* has for its fruit a berry with 8–10 cells, each cell one-seeded. *P. decandra*, the Poke or Pocom, a native of North America, now naturalized in some parts of the south of Europe, is sometimes cultivated for its young shoots, which, when blanched, are eaten like asparagus, though the leaves are acrid. The root is an emetic, and is applied externally for itch and ringworm. A preparation of the berries is used in rheumatism and syphilis, and for the adulteration of wine.—The young shoots of *P. acinosa* are boiled and eaten in the Himalayas, those of *P. octandra* in Cayenne, and a Chinese species has recently been introduced into British gardens under the name of *P. esculenta*.

PHYTOZOÏA (Gr. *phyton*, a plant; *zoon*, an animal), also called *Antherozoids*, are minute bodies produced amidst a mucilaginous

among plants, each cell is devoted to the production of a single phytozoon. When the antheridium is mature, and bursts, the phytozoa move for a short time by means of cilia—a provision, apparently, for their reaching the pistillidia, the spores contained in which—according to an opinion rapidly gaining ground among botanists—they are destined to fertilize. Great diversities exist in the phytozoa of different cryptogamous plants. The annexed figure will convey a better notion of them than any mere description. Cryptogamous plants, which as lichens, live in dry situations, have no phytozoa, although it is supposed that they have organs destined to the same purpose, but destitute of the power of motion by cilia.

PIACE'NZÀ, a city of Northern Italy, in the province of the same name, on the right bank of the Po, 2 miles below the confluence of the Trebbia with that river, and 36 miles west-north-west of the city of Parma. Beautifully situated on a fine plain, confined on the south by well-cultivated hills, the city itself is gloomy and desolate in appearance. Its streets are broad and regular—that called the *Stradone* is one of the most beautiful in Italy—but many of them are unfrequented and grass-grown. It contains numerous palaces, and about 50 churches. The cathedral, an edifice in the ancient Lombard style, founded in the 11th c., is famous for the richly curious and grotesque character of its internal decorations, for its numerous sculptures, its paintings, and for a number of frescoes of great grandeur, by Caraccio, Guercino, and others. The Church of Sant' Antonio, the original cathedral of P., was founded in 324 A.D., but has been several times rebuilt. Among the other principal buildings, are the Palazzo Farnese, founded in 1558, and once a sumptuous edifice, but which has been long in use as a barrack; the Palazzo del Comune, and the Collegio dei Mercanti are fine monuments of art. The principal square is the Piazza Cavalli, so called from the colossal bronze equestrian statues of the dukes Alessandro and Rannuccio Farnese. This town occupies by far the most important position, in a military point of view, in Italy—a fact which was fully appreciated by those who fortified it with solid walls and a strong castle, which, till 1859, were guarded by the Austrians. On being forced from the city by the war of 1859, the Austrians did not destroy the works, and the Italian government has strengthened and extended them by the formation of externally defended works, and of a formidable entrenched camp, which unites and protects the other works on the right bank of the Po. Manufacturers of silks, fustians, linens, hats, &c., are carried on to some extent. The population, which had almost kept stationary during the previous ten years, was 34,925 in 1881.

P., called by the Romans *Placentia*, on account of its pleasing situation, is first mentioned in 219 B.C., when a Roman colony was settled there. In 200 B.C., it was plundered and burned by the Gauls, but rapidly recovered its prosperity, and was long an important military station. P. was the western terminus of the great Æmilian road, which began at Ariminum on the Adriatic. In later history, it plays an important part as one of the independent Lombard cities.

PIA MA'TER. See NERVOUS SYSTEM.

PIA'NA De' GRE'CI, a town of Sicily, 10 miles south-west of Palermo. It was the chief colony of the Albanians who settled in Sicily in the 15th c. Pop. 7500.

PIA'NO (Ital. *soft*), abbreviated *p*, is used in music to denote that the strain where the indication occurs is to be played with less than the average intensity of force. *pp*, or *ppp*, *pianissimo*, signifies very soft, or as soft as possible. In contra-distinction from *piano*, *forte*, abbreviated *f*, is used to denote a more than usual force; and *ff*, or *fff*, for *fortissimo*, a still greater degree of force. The gradual transition from *piano* to *forte* is indicated by the sign <; from *forte* to *piano* by the sign >.

PIANOFO'RTÉ (Ital. *piano*, soft, and *forte*, loud), a stringed musical instrument, played by keys, developed out of the clavi-chord and Harpsichord (q. v.), from which the pianoforte differs principally in the introduction of hammers, to put the strings in vibration, connected with the keys by a mechanism that enables the player to modify at will the intensity of the sounds; whence the name of the instrument.

The idea of the pianoforte was conceived independently about the same time by three persons in different parts of Europe—a German organist of the name of Schröter; Marius, a French harpsichord-maker; and Bartolomeo Cristofali, a harpsichord-maker of Padua. Priority in point of invention (1714) is due to the Italian maker. Schröter's discovery was followed up in Germany by Silbermann of Strasburg, Spät of Ratisbon, Stein of Augsburg, and others. The first pianoforte seen in England was made at Rome by Father Wood, an English monk there. A few German manufacturers and workmen settling in London, gave an impetus to the new instrument. The English pianoforte has been brought to its present state of perfection by Broadwood, Stodart, Collard, Worrum, Hopkinson, and others. Erard and Petzold

Phytozoa:
(From Carpenter on the Microscope.)

- A. Antherozoids of *Fucus platycarpus* (a sea-weed) some of them free, others still included in their antheridial cells.
- B. Cellular contents of an antheridium of *Polytrichum commune* (a moss), mature and discharging the antherozoids.
- C. Antherozoid of *Pteris serrulata* (a fern) showing a, its large extremity; b, its small extremity; d, d, its cilia.

fluid in the antheridia of many cryptogamous plants (Algae, Hepaticae, Mosses, Ferns), which are either aquatic or delight in moist situations. In some many-celled antheridia of the higher cryptog-

made many improvements in France; Germany has long been famous for its pianos; American makers have lately become well known. The compass of the early pianoforte was, like that of the harpsichord, 4 to 5 octaves, and has gradually increased to 6½, or 7 octaves, or occasionally more.

The most natural of the various forms which the instrument assumes is that of the grand pianoforte, derived from the harpsichord, with the strings placed horizontally, and parallel to the keys. The strings are stretched across a compound frame of wood and metal, composed of bars, rods, and strengtheners of various kinds—appliances necessary to resist the enormous tension. This framework includes a wooden sound-board. The mechanism by which hammers are connected with the keys, is called the *action* of the instrument. In the earliest pianofortes, the hammer was raised from below by a button attached to an upright wire fixed on the back-end of the key. The impulse given to the hammer caused it to strike the string, after which it immediately fell back on the button, leaving the string free to vibrate. This was called the *single action*. As the hammer, when resting on the button with the key pressed down, was thus necessarily at a little distance from the string, the effectual working of this action required that a certain impetus should be communicated to the hammer to enable it to touch the string. Hence it was impossible to play very piano, and it was found that if the hammer was adjusted so as to be too close to the string when resting on the button, it was apt not to leave the string till after the blow had been given, thereby deadening the sound. This defect was remedied by a jointed upright piece called the *hopper*, attached to the back-end of the key, in place of the wire and button. When the key was pressed down, the hopper, engaging in a notch in the lower side of the hammer, lifted it so close to the hammer, that the lightest possible pressure caused it to strike; and at this moment, when the key was still pressed down, the jointed part of the hopper, coming in contact with a fixed button as it rose, escaped from the notch, and let the hammer fall clear away from the string.

To prevent the hammer from rebounding on the string, a projection called the *check* was fixed on the end of the key, which caught the edge of the hammer as it fell, and held it firmly enough to prevent it from rising. A necessary part of the action is the *damper*, which limits the duration of each particular note, so as to cause it to cease to sound as soon as the pressure is removed from the key. It consists of a piece of leather resting on the top of the string, and connected with the back-part of the key by a vertical wire. When any key is pressed down, its damper is raised off the string, so as to allow the sound produced to be clear and open; but immediately on the finger being lifted off the key, the damper-wire falls, and the damper again presses on the string, muffling and stopping the vibration. The whole range of dampers may, when required, be raised by the use of the damper pedal, so as to prolong the sound of one note into another.

One further frequent and important addition to the action may be alluded to. In the mechanism above described, the key must rise to its position of rest before the hopper will again engage in the notch of the hammer for another stroke; hence, a note cannot be repeated until time has been allowed for the full rise of the key. The *repetition action* is a contrivance, varying in different instruments, for getting rid of this defect, by holding up the hammer at a certain height while the key is returning.

Great difference of detail exists in the actions of different makers. Some are more complicated than others; but in all are to be found the same essential parts, only modified in shape and arrangement. The subjoined figure represents one of the simplest grand pianoforte actions now in use. A is the key, B the lever

which raises the hammer, C the hammer, D the string, and E the damper; F is the button which catches the lever after it has struck the hammer, G the check, H the damper pedal-lifter, I the spring, and K, K, K are rails and sockets.

Formerly, the strings of the pianoforte were all of thin wire; now, the bass-strings are very thick, and coated with a fine coil of copper-wire; and the thickness, strength, and tension of the strings all diminish from the lower to the upper notes. A grand pianoforte has three strings to each of the upper and middle notes, and now, generally, only two to the lower notes, and one to the lowest octave. When the soft pedal is pressed down, the hammers are shifted sideways, so as to strike only two strings instead of three, or one string instead of two.

Besides the grand, the kinds of pianoforte in use are the square, in which the strings are placed still in a horizontal position, but obliquely to the keys; and the upright, in which the strings run vertically from top to bottom of the instrument. The difference in form necessitates alterations in the details of the action, but the general principle is the same.

The pianoforte has in modern times attained a widespread popularity beyond that of any other musical instrument. It possesses nearly all the powers of expression of any other instrument; on no other except the organ can we execute such complete successions of harmonies; no other represents the orchestra so well, with the advantage that the various parts adapted to it are brought out by the same performer. In all cities of the civilized world, there are numerous manufacturers of the pianoforte, employing multitudes of workmen; and even in the secondary towns of Europe, the number of makers is daily increasing. In England, the manufacturers who have for some time past enjoyed the highest repute are Messrs. Broadwood, Collard & Co., and Erard; but other makers are rapidly approaching them in excellence. Till lately, the German makers adopted a much less perfect action than the English, producing a very different touch and tone; but they are now largely using the English action, which is spreading over the continent. Music for the pianoforte is written in two staves, and on the treble and bass clefs. Many of the most eminent musicians have devoted themselves to composing for the pianoforte, and some composers of note, as Hummel, Czerny, Kalkbrenner, Chopin, Thalberg, Liszt, and Heller, have almost entirely confined themselves to that instrument. See Rimbault, *The Pianoforte* (1860); and Grove's *Dictionary of Music and Musicians*.

PI'ARISTS, called also familiarly *Scolopini*, or 'Brethren of the Pious Schools,' a religious congregation for the education of the poor, founded at Rome in the last year of the 16th century. The originator of this institute was a Spanish priest, named Joseph of Calasanza, who, while in Rome, was struck with the imperfect and insufficient character of the education which then prevailed, even for the children of the higher classes, and conceived the idea of organizing a body for the purpose of meeting this want, which the Jesuit Society had already partially supplied. The school which he himself, in conjunction with a few friends, opened, rapidly increased in number to 100, and ultimately to 700 pupils; and in 1617, the brethren who, under the direction of Joseph, had associated themselves for the work, were approved as a religious congregation by Paul V. (q. v.), who entered warmly into this and all other projects of reformation. In 1621, Gregory XV. approved the congregation as a religious order. The constitution of the order was several times modified by successive popes, down to the time of Innocent XI. Its field of operations has, of course, been confined to European countries; and at present it can reckon communities in Italy, Austria, Spain, Hungary, and Poland. In Italy, during the revolutionary wars, the P. received into their ranks many members of the suppressed Society of the Jesuits. In Spain, their establishments were spared, on the general suppression of religious orders in 1836. In Poland, eleven houses still were in existence in 1832. The number of members in Hungary is said to be about 400, and the order is also found in the German and Slavonic parts of the Austro-Hungarian Empire.

PIA'SSABA, or PIACABA, a remarkable vegetable fibre which, during the last twenty years, has become an article of much importance in this country. It is procured from Brazil, chiefly from the parts of Para and Maranhão, and is produced by one or more species of palm. That which furnishes the greater part is the Coquilla-nut Palm (*Attalea funifera*); but Mr. Wallace states that much of it is procured from a species of *Leopoldinia*, which he has named *L. piassaba*. The fibre is produced by the stalks of the large fan-like leaves. When the leaves decay, the petioles or stalks split up into bundles of cylindrical fibres of a dark-brown color, and of a hard texture, varying in thickness from that of a horse-hair up to that of a small crow-quill. This material has been found of great utility in making brushes of a coarse kind, particularly those required to sweep the street; and for this purpose they have almost superseded birch-brooms, split whale-bone brushes, and other similar means for scavengers' work. The coarsest fibres are best for such purposes, and the finer ones are found very valuable for finer kinds of brushes.

PIA'STRE (Gr. and Lat. *emplastron*, a plaister; transferred in the Romanic languages to anything spread out or flattened, a plate, a coin), a Spanish silver coin which has been extensively adopted by other nations. It was formerly divided into 8 silver reals, and hence was termed a *piece of eight*, which name was invariably applied to it by the Buccaneers of the Spanish Main. The present Spanish piastre, commonly known as the *peso duro*, *peso fuerte*, or, briefly, *duro*, is the standard of the money system, and is equivalent to about 4s. 8d. of our money. It is divided into 20 copper reals (*reales de vellón*). In the Levant, the plaister

is called a *colonnato*, on account of the original coins, which were struck for use in Spanish America, bearing two columns on the reverse side.—The Italian piastre, or *scudo*, was an evident imitation of the Spanish coin, and was exactly equal to it in value.—The piastre, peso, or dollar in use in Mexico and Cuba, as well as in Chili, Peru, Uruguay, and other South American states of Spanish origin, have approximately the same value (4s. or 4s. 2d.) The Dollar (q. v.) of the United States of North America was adopted from the Spanish piastre, but is a fraction less in value, owing, it is said, to an error in the original estimate.

The coin known as the Turkish piastre is not an imitation, but is an independent national silver coin, which in 1753 was worth about 3s. 6d. sterling, but has since gradually and rapidly deteriorated, till at the present day it is equal to not more than 2½d. of our money.—The Egyptian piastre is worth about 2½d. sterling. Pieces of 2, 5, 10, and 20 piastres are struck in silver, and of 50 and 100 in gold; the piece of 100 piastres being in Egypt the exchange at par for £1 sterling.

PIATIGORSK (*Pjätigorsk*), a town in Caucasia, Russia, celebrated for its mineral springs. Though in the center of a bare and uninteresting plain, its situation on the slope of Mashûka, an isolated mountain upwards of 3000 feet high, gives it an imposing appearance, and the higher parts of the town command a noble panoramic view of Mount Elburz and the more distant Caucasus. The principal bath-houses are well sheltered, and are cleanly and comfortably fitted up. Pop. (1880) 13,600.

PIATRA, a town of Moldavia, 63 miles west-south-west from Jassy, on a branch of the Sereth. There are paper-mills here. Pop. about 20,000.

PIA'ZZA (more fully *P. Armerina*), a town of Sicily, 17 miles east-south-east from Caltanissetta. The chief trade is in corn, oil, fruits, and other agricultural produce. Pop. 16,000.

PIAZZI, GIUSEPPE, a celebrated astronomer, was born at Ponte in the Valteline, July 16, 1746. He was received into the order of the Theatins at Milan in 1764; and studied in that city, and subsequently in the houses of the same order at Rome and Turin. Summoned to the professorial chair of Philosophy at Genoa, he so alarmed the Dominicans by the freedom and boldness of his opinions, that he was removed to Malta, where, in 1770, he became Professor of Mathematics in the newly-founded university. On the breaking up of this seminary, he returned to Italy, and after teaching philosophy in the Nobles' College at Ravenna, he went to Rome, where he became Professor of Dogmatic Theology in the institution of San Andrea della Valle. He was transferred in 1780 to the chair of Mathematics in Palermo, where, with the aid of government, he established an observatory, which was put in working order in 1789. The first results of his observations were, the rectification of some errors in the estimation of the obliquity of the ecliptic, the aberration of light, the length of the tropical year, and the parallax of various heavenly bodies; these results were published in 1792. P. had now attained a European reputation, which was further heightened by his discovery, on the night of 1st January 1801, of a new planet, the first known of the great group of planetoids between Mars and Jupiter. P. was only able to give a description of it to some of the German and Italian astronomers, when it disappeared; Gauss (q. v.), however, rendered certain the fact of its being a planet. P. named it Ceres, after the ancient goddess of Sicily, to which country he was sincerely attached. In 1803, he published a map of the fixed stars, far superior to any before published, the result of ten years' observations: the work was crowned by the Institute of France. In 1814, appeared a new and more complete catalogue (containing 7646 stars), for which he was again rewarded with a prize from the French Institute. He also made researches into the nature of comets, and devoted the later years of his life to the improvement of public education in Sicily. He wrote a number of works, of which, besides the catalogues of stars above mentioned, the *Lezioni Elementari di Astronomia* (Palermo, 1817) is the chief. He also wrote many memoirs for the various scientific societies of Europe. P. died, 22d July 1826, at Naples.

PI'BROCH (*piobaireachd*, piping), music played on the bagpipe, which has a wonderful power in exciting the martial instincts and hilarity of the Highlanders. Its rhythm is so irregular, and its notes in the quicker parts so much jumbled together, that a stranger has difficulty in following the modulations or reconciling his ear to them. The earliest mention of the military music of the bagpipe is in 1594, at the battle of Balrinnies; indeed, prior to that period, the bagpipe can hardly be looked on as a national instrument of Scotland. There are appropriate pibrochs belonging to various clans and districts, but some of these may not be older than the beginning of last century. One of the oldest known pibrochs is called the 'Battle of Harlaw,' but it may be doubted whether it was contemporary with that event (1411). In the ballad account of that battle, there is mention of trumpets and horns, but none of the bagpipe; and the pibroch style of

music has so obvious a relation to the bagpipe, that it is difficult to suppose that it preceded the use of that instrument. According to Sir Walter Scott, the connoisseurs in pipe-music affect to discover in a well-composed pibroch the imitative sounds of march, conflict, flight, pursuit, and all the current of a heady fight. Many remarkable instances have been recorded of the effect of the pibroch on the Highlanders. At the battle of Quebec, in April 1760, whilst the British troops were retreating in confusion, the pipers were ordered to strike up a favorite pibroch, and the result was that the Highlanders, who were broken, rallied the moment that they heard the music, and formed with great alacrity in the rear.

PICARDY (PICARDIE), an ancient province in the north of France, was bounded on the W. by the English Channel, and on the E. by Champagne. The name does not occur till the 13th century. The capital of this province was Amiens. The territory now forms the department of *Somme*, and portions of the departments of *Aisne* and *Pas-de-Calais*.

PI'CCOLO (Ital. *flauto piccolo*, small flute), a flute of small dimensions, having the same compass as the ordinary flute, while the notes all sound an octave higher than their notation. In joyous as well as violent passages, this instrument is sometimes very effective in an orchestra.

PICCOLOMINI, one of the oldest and most distinguished families of Italy, was originally settled at Rome, but afterwards removed to Siena, and subsequently obtained possession of the duchy of Amalfi. It has produced numerous celebrated *littérateurs* and warriors, one pope (PIUS II.), and several cardinals. One of the most distinguished in the history of this family was OTTAVIO P., the first Duke of Amalfi, born in 1599, and fifth in direct descent from Pope Pius II. He early entered the Spanish military service, and after taking part in the Milanese campaigns, was sent as captain with a Florentine cavalry regiment to aid Ferdinand II. against the Bohemians. As a cavalry leader, he distinguished himself; and from the regiment of cuirassiers under his command issued the death-dealing bullet to Gustavus Adolphus. In 1634, he was placed under the orders of Wallenstein, who took a great fancy to him, and confided to him his secret designs against the emperor; P.: however, communicated these designs to the emperor, and received, as a reward for his fidelity, a part of Wallenstein's estates. During the remainder of this year, he was actively engaged against the Swedes, and greatly distinguished himself in the first battle of Nordlingen. In the following season he was sent with 20,000 troops to aid the Spaniards in the Netherlands, where the French and Dutch were carrying all before them.

P. speedily drove out the French, but his success against the Dutch was not so marked. He was withdrawn by the emperor in 1640 to stay the Swedes, who, under Baner, were threatening the hereditary possessions of Austria; and his success against these invaders in Bohemia and the Palatinate, though damped by the defeat inflicted on him in Silesia by Torstensohn, induced the king of Spain to entreat the emperor to send him again to the Netherlands to take the command of the Spanish troops. But his success was not nearly so decisive as before, the prestige of the Spanish infantry having been completely destroyed by the great Condé at Rocroi (19th May 1643). P., however, was again successful against both the French and Dutch till 1648, when he was anew summoned to Germany to encounter the victorious Swedes; but after a brief campaign, the peace of Westphalia (1648) put an end to his career. He was created a field-marshal by the emperor, and was sent as plenipotentiary to the Congress of Nuremberg (1649), and soon after was raised to the high dignity of a prince of the empire. The king of Spain conferred upon him the order of the Golden Fleece, and bestowed upon him in fief the duchy of Amalfi, which had previously belonged to his family. P. died at Vienna, 11th August 1656, leaving no children; his son Max, who figures in Schiller's *Wallenstein*, is only a poetical fiction. His fame as a warrior and general is somewhat tarnished by his cruel treatment of a number of Hessian and Luneburger prisoners in 1640.

PICHEGRU, CHARLES, a French general, was born 16th February 1761, at Arbois, in the department of Jura, France. Though of humble parentage he succeeded in gaining admission to the college of his native town, where, and subsequently at Brienne, he received a thorough education. He was specially distinguished in mathematics, and had some thoughts of devoting himself to teaching as a profession; but the advice of Father Peault induced him to enter an artillery regiment in 1783, and he had risen to the rank of a lieutenant when the Revolution broke out. P. became an ardent democrat; joined the army of the Rhine, and by his brilliant soldierly qualities soon attracted gen-

eral attention. In 1793, he became commander-in-chief of the army, and in conjunction with the army of the Moselle under Hoche, repeatedly defeated the Austrians; took from them many important towns, as Gemersheim, Spire, Worms, &c., and established himself in the Palatinate; while, after the arrest of his coadjutor Hoche, his success at the head of the combined Rhine and Moselle armies was not less decided. The rapidity and boldness of his manœuvres, when he took the command of the army, of the north, in 1794, disconcerted the allies; and before long they were compelled to retreat beyond the Meuse. After a brief respite, P. crossed this river, driving the British before him; and by February 1795, had completed the conquest of the Dutch towns and provinces, ending the campaign by capturing the enemy's fleet (which had been frozen in). He next visited Paris, and while there, suppressed an insurrection of the faubourgs (1st April 1795); but soon afterwards returned to the army, which was now opposed to the Austrians on the western frontier, and for some time displayed his usual skill and energy, crossing the Rhine in the face of the enemy, and capturing Mannheim, the chief fortress, on its banks.

But the anarchy which he had found at Paris, combined with the flattering promises and bribes held out to him by the Prince of Condé, converted P. into a secret partizan of the Bourbons. His remissness, the unwonted folly and awkwardness of his military manœuvres, though prearranged with the Austrian generals, was not suspected till he suffered himself to be shamefully defeated at Heidelberg, and then retreated, leaving Jourdain (q. v.) without support, thus compelling the latter also to retire. The suspicious of the Directory were now aroused, and being confirmed by the seizure of P.'s correspondence, he was immediately superseded by Moreau (q. v.), and retired to his native town, where he lived till 1797, when he was elected one of the council of Five Hundred. He soon became president; but continuing his intrigues with the Bourbons, he was arrested, and subsequently transported to Cayenne. Escaping in July 1798, he made his way to Surinam, whence he sailed for England. He now entered heart and soul into the Bourbon conspiracy along with George Cadoudal (q. v.), the two Polignacs, De Rivière, and others, the primary object being the assassination of the First Consul. The conspirators secretly reached Paris, and there P. attempted to persuade Moreau, who was also a royalist, to join with them, but without success. But the plans of the conspirators were soon known to the police; and an intimate friend of P., with whom he resided, sold the secret of his retreat to the police for 100,000 crowns. P. was surprised in his sleep, and carried off naked to the Temple, where he was found dead in his bed on the morning of 6th April 1804. The Royalists have endeavored to fasten a charge of private assassination on Napoleon, but it is more generally believed that P. strangled himself.

PICHINCHA, an extinct or dormant volcano in the west cordillera of the Andes, in Ecuador, about ten miles north-west of Quito. It is of irregular form, and is 15,924 feet in height. Around the crater are two other peaks of nearly equal elevation. There have been five eruptions since the Spanish Conquest, the last in 1660. That in 1566 covered Quito with three feet of ashes and stones. P. was one of the many peaks of the Andes of Ecuador ascended in 1879-80 by Mr. Edward Wympyer.

PICHLER, KAROLINE, a German novelist, was born in 1769 at Vienna. Her maiden name was Greiner. In 1796, she published her first work, *Gleichnisse* (1800). The success which attended the appearance of *Oliver* (1802), *Leonora*, and *Ruth* encouraged her to try a more ambitious line of composition. In 1808 appeared *Agathokles*, which, according to some critics, is the best of her novels. In this work, she endeavored, in opposition to the views expressed by Gibbon, in his *History of the Decline of the Roman Empire*, to depict the ennobling effect of Christianity on the human mind. At the suggestion of Hormayr and other literary friends, who had been struck by the success with which she threw herself into the spirit of the times of which she wrote, she turned her attention to the task of popularizing the German history, with the view of fostering a more general feeling of patriotism. Among her best works of this kind, which appeared between 1811 and 1832, and the earlier of which preceded Scott's greatest historical novels, we may instance *Grafen von Hohenberg* (Leip. 1811); *Die Belagerung Wien's von 1683* (Wien, 1824); *Die Schwestern in Prag* (Wien, 1827); and *Henriette von England* (Wien, 1832); while of her social novels the following are among the most popular: *Frauenwürde* (Wien, 1808); *Die Nebenbuhler* (Wien, 1821); and *Zeitbilder* (Wien, 1840). She died at Vienna in 1843. Her dramas were failures, and in her novels there is not a little tedious diffuseness, a remark which applies with equal truth to her autobiography, which appeared at Vienna in 1844 under the title of *Denkwürdigkeiten a. m. Leben*, and formed part of the edition of her collected works, published at Vienna in 1845 in sixty volumes.

PICKET, in Military Language, has several significations. It applies to a stake shod and sometimes ringed with iron, driven into the ground, and used to sustain ropes, which mark off sections in a camping-ground, or for tying horses to. These pickets are four or five feet long. Short pickets about eight inches long are employed as anchors for the ropes extending tents.—In Fortification, pickets are pointed stakes for pinning gabions together and to the ground; also, when pointed at both ends, and laid close together, of different lengths, and in a position inclined towards the front, they form a powerful obstruction to the advance of a storming-party, having a great effect in breaking a line of soldiers.—*Picket* was formerly a military punishment, where the culprit was held by the raised arm in such a position that his whole weight fell on one foot, which was supported on a picket with a blunt point. The time the man thus stood was proportioned to the offence. The punishment became after a few moments, extremely painful: it has long been discontinued on sanitary grounds.—The word *picket*, when applied to a small guard of men, is ordinarily written *Piquet* (q. v.).

PICKLES. Although the term *pickled* is applied to animal substances, such as beef, pork, fish, &c., preserved in salt, yet pickles are generally understood to be the various parts of vegetables preserved in vinegar. The process employed is first to wash the articles intended for pickles in clean cold water, and afterwards to soak them for a few days in a strong solution of salt in water. They are next taken out, and if fruits or roots, dried in a cloth; but if vegetables, such as cauliflower, &c., they must be well drained, and then placed in the vessels intended to hold them, a few peppercorns, or any other spice which is suitable, being sprinkled in from time to time. When the vessel is so far filled that it will hold no more, boiling vinegar is poured in until it is quite full, and tightly covered up. Many persons prefer to boil the spices, of whatever kind used, in the vinegar; and some add the vinegar cold to such vegetables or fruit as are of a naturally soft substance, because, except in the case of green walnuts, and one or two other fruits, extreme softness is objectionable in pickles.

When the materials to be pickled are naturally green, as in the case of gherkins or small cucumbers, French beans, &c., it is considered very desirable to preserve their color as much as possible; and it is sometimes very successfully accomplished by steeping vine, cabbage, spinach, or parsley leaves in the vinegar, by which their color is imparted through the vinegar to the pickles. But this requires great care and patience, more, indeed, than is generally thought worth applying to it, and dealers consequently resort to very reprehensible methods of coloring their pickles, such as boiling the vinegar in copper vessels, and thereby forming an acetate of copper, which is green; or even directly adding that salt to the pickles. Many serious accidents have resulted from the presence of this poison.

The principal pickles made in this country are *cabbage*, almost always made from the red variety; to this is frequently added slices of beet-root, which are an agreeable addition, and improve the color. The celebrated Spanish pickle is a mixture of the red cabbage and slices of the large Spanish onion. Some housewives, in their efforts to out rival their neighbors, add a little cochineal to improve the color. The spices considered most suitable for pickled cabbage are white and black peppercorns, ginger and mace.—*Cauliflowers*. Only the flower portion, with its white branches, is used, and in other respects they are treated as cabbage.—*Gherkins*, or very young cucumbers. These require the same spices as the cabbage; but much care is required to keep as well as possible their green color. This pickle is the one which British cooks and housewives most pride themselves upon making well; and almost every one has some particular plan for its preparation. A very much approved method is to soak the gherkins in a brine, composed of six ounces of salt to the quart of water for twenty-four hours, then drain or dry in a cloth, place them in jars, and pour in the pickle, composed of vinegar, with an addition to each quart of one ounce salt, black peppercorns a quarter of an ounce, one ounce of ginger slightly bruised, one or two blades of mace, and a dozen bay-leaves. After soaking two days, they are set on the fire until they simmer, and then replaced in the jars, which must be well corked, and covered with skin, to exclude the air.—

French Beans.—The young green pods are prepared in the same way as gherkins.—*Onions and Eschalots* are carefully peeled, and, after two days' steeping in brine, covered with boiling vinegar, to which the spice, usually black pepper corns, has been added. A small variety of onion, called the silver-skin, is generally used.—*Walnuts*.—These are gathered green, and so tender that a pin can easily be pushed through them; they are useless when the shell has begun to form. They require at least a week's steeping in the brine. The vinegar must be poured on them boiling hot. The spices used are peppercorns, mace, ginger, and sometimes a little garlic and cloves.—*Mushrooms* are sometimes pickled only in brine, and

are very useful for gravies, &c., in winter-time. They are also preserved in vinegar, and must be washed in salt and water quickly, and then boiled in vinegar, to which, besides the spices, a small quantity of salt is added.—*Nasturtium*. The young green fruit or seeds of the Nasturtium plant, or greater Indian Cress (*Tropaeolum nasturtium*), make a most excellent pickle, which is an admirable substitute for the foreign capers in sauces for various dishes, and alone is an agreeable pickle.—Several kinds of mixed pickles are made, the chief of which is one called *Picailly*, or 'Indian Pickle,' which consists of a mixture of cucumber, cauliflower, &c., with a considerable quantity of mustard-seed and flower of mustard used as a spice, which gives it a bright yellow color.

Of the foreign pickles imported from other countries, we have the unopened buds of the beautiful plant *Capparis spinosa*, called *Capers*; olives, pickled both in brine and vinegar, but chiefly in the former—both from Southern Europe. From tropical countries, every variety of the capsicum—green shoots of bamboo—and the fruit of the mango, which is much esteemed wherever it is known, notwithstanding a turpentine flavor, which is not agreeable at first. Besides these, there are numerous other pickles of less importance, almost every soft part of wholesome vegetables being adapted for this mode of preparation. Pickles generally are considered provocatives to appetite, and if used judiciously, and made properly, are wholesome and agreeable additions to our food.

PI'CO, one of the Azore Islands, stands midway between the eastern and western extremities of the group, a few miles south-east of Fayal. It is 45 miles long, and 5 miles in average width; area about 225 square miles; pop.—the descendants of Portuguese—about 30,000. It is traversed by a volcanic ridge, which rises 7613 feet high in the Peak (Pico), whence the name of the island. See AZORES.

PICO, GIOVANNI, DELLA MIRANDOLA, an Italian philosopher and theologian, whose genius is decidedly inferior to the reputation he once enjoyed, was the son of the sovereign prince of Mirandola and Concordia, and was born 24th February 1463. At the age of 14, he was sent to the university of Bologna, and after spending some years there, visited the principal schools of Italy and France, everywhere distinguishing himself by the extraordinary facility with which he mastered the most difficult branches of knowledge. His linguistic acquisitions embraced Latin, Greek, Hebrew, Chaldee, and Arabic, besides Italian and French; he was familiar with the different phases of the scholastic philosophy, and he was also versed in mathematics, logic, and physics. At the age of 23, he returned to Rome, when Innocent VIII. was pontiff, and immediately sought an opportunity of showing his learning in the most striking manner, by publicly posting up no fewer than 900 theses or propositions in logic, ethics, physics, mathematics, theology, natural and cabalistic magic, drawn from Latin, Greek, Jewish, and Arabic writers, offering to maintain an argument on each against all the scholars of Europe, and undertaking to pay the expenses of those who came from a distance. P. presumptuously entitled his theses *De Omni Re Scibili* (On Everything that can be Known), and Voltaire sarcastically added, *et de quibusdam aliis*, which addition is as true as it is witty. P. had several encounters with notable scholars, and is reported to have come off victorious on every occasion. But his very success was the cause of misfortune. The church appointed a committee to report on the propositions of the young prince, and the result was that several of them were condemned as 'heretical,' although the author was acquitted of any heretical intentions.

P. now withdrew from Rome, and after a short time settled in Florence, where he austere devoted his whole time to the composition of polemical treatises against Jews and Mohammedans, and to the refutation of judicial astrology. Among his closest friends were Politian and Ficino. He died 17th November 1494, at the early age of 31. A complete edition of his works was published at Bologna in 1496; it has since been frequently reprinted. The principal are *Heptaplus, id est de Dei Creatoris Opere sex Dierum Libri Septem.*, an allegorical explanation of Creation as recorded in the Book of Genesis; *Conclusiones Philosophicae, Cabalisticae et Theologicae*—these are the famous propositions which excited so much ferment at Rome; *Apologia Concordia Comitibus; Disputationes adversus Astrologiam Divinatricem Libri xii.*; *Aurea ad Familiare Epistola; De Hominis Dignitate*. P. is a happy illustration of the immediate effects produced in literature by the 'revival of letters;' he is full of a specious kind of universal learning, zealous and enthusiastic, but destitute of originality, depth, or creative power. 'He was,' says M. Matter, 'a prodigy of memory, elocution, and dialectics, but neither a writer nor a thinker.'

PICOTEE. See CARNATION.

PICRIC ACID. See CARBAZOTIC ACID.

PICROTOXINE (C₁₀H₈O₄) is the active principle of *Cocculus indicus*, from which it may be extracted by boiling alcohol, or by

water containing a little hydrochloric acid. It crystallizes in colorless prisms. This substance is extremely poisonous, one-third of a grain being sufficient to kill a cat in ten minutes.

PICTOU', a thriving seaport on the north coast of Nova Scotia, on the north shore of an ample and perfectly protected harbor, 85 miles in direct line north-north-east of Halifax. Lat. of light-house, 45° 41' N.; long. 62° 40' W. It stands in a fertile and well-cultivated district, with extensive coal-mines and quarries of building-stone in the vicinity. It exports building-stone, dried fish, and potatoes. Commerce is rapidly increasing; ship-building is vigorously carried on in Pictou. The mean summer temperature is 63° 52, and the mean temperature for the year is 42° 09. Population (1881) 3403.

PICTS, the ancient inhabitants of the north-eastern provinces of Scotland. Everything connected with the history of the P. has been made matter of controversy, and it is not easy to ascertain the truth, where the information given by early writers is so scanty, and where most modern authors seem only to have looked for materials to support a favorite theory.

It will be unnecessary to enter on an examination of the name itself. The 'Picti' of the Romans probably represented a word by which the nation was known in its own language, as well as the barbaric custom to which the well-known expression of Claudian, 'nec falso nomine Pictos,' bears reference. Of much more importance is the inquiry regarding the origin and language of the Picts. This is what, among Scottish antiquaries, has been emphatically called 'the Pictish question,' respecting which the best-known and most amusing, and certainly not the least useful discussion, is that between Jonathan Oldbuck and Sir Arthur Wardour, in the sixth chapter of *The Antiquary*. The disputants can hardly even now be said to be agreed; but the prevailing opinion is, what sound criticism always pointed to, that the P. were a Celtic race—perhaps the first known inhabitants of Northern Britain, and (as some hold) to be identified with the Caledonians of the Roman writers. At the time when they became generally spoken of under the name of P., they occupied the whole territory north of the Firth of Forth, except the western portion, which had been colonized or subdued by the Scots, another Celtic nation, whose chief seat was in Ireland—the proper and ancient Scotland. The southern boundary of the P. was the Roman province of Valentia, embracing the territory between the two Roman walls. At a later period, when Britain was abandoned by its imperial rulers, the boundaries of the various nations occupying the northern part of the island may be traced with considerable distinctness.

Making allowance for partial changes at various times, these boundaries may be held to be the following: The Pictish territory extended along the whole sea-coast from the Firth of Forth to the Pentland Firth. It was bounded on the west by the country of the Scots, which extended along the western coast from the Firth of Clyde to the modern Ross-shire; but the precise line between the two nations cannot be ascertained. The country of P. was bounded on the south by the Firth of Forth and the province of Lothian, then possessed by the English; while the country of the Scots had for its southern boundaries the Firth of Clyde and the kingdom of Cumbria, held by the independent Britons.

The Pictish nation consisted of two great divisions, called the Northern and Southern P., the boundary between them being the mountain range known afterwards as the Grampians. These divisions seem at some time to have been ruled by different princes, at other times to have been under one sovereign. The P. were converted to Christianity at different periods. The Southern P. received the faith from St. Ninian, Bishop of Candida Casa, early in the 5th century. This is mentioned by Bede, and the fact itself has never been doubted; but controversy, as usual, has been busy with the details. The point in dispute is the situation of the P. who owed their conversion to Ninian (q. v.). A careful examination of the statements of Venerable Bede, and the fuller but less trustworthy narrative of Alired of Rievaulx, will show that the Southern P., converted by Ninian, had their seat north of the Forth; that they were, in fact, the great division of the Pictish nation occupying the country between the Firth and the Grampians. The labors of Ninian were carried on and completed by teachers whose names are well known to the readers of ecclesiastical history—Palladius, Serf, Ternan, and others. The Northern P. owed their conversion to a teacher of higher renown—St. Columba (q. v.). The life of that abbot, from his leaving Ireland in 563, to his death in 597, was chiefly spent in converting the Northern Picts. Their ruler at this time was Brude, son of Mailcon, whom Bede styles a very powerful king. His chief residence was on the banks of the Ness, and there Columba baffled and confuted the heathen Magi in the manner recorded by his biographer Adamnan.

It is impossible to ascertain the precise character of the superstitions held by the P. before their conversion. Those whom Adamnan calls Magi, are by some modern writers styled Druids,

and their religion is said to have been a species of Druidism—whatever that may be held to mean.

Brude, the first Christian king of the P., died in 586. Catalogues are preserved, of more or less authority, of the sovereigns who succeeded him. It is impossible to reconcile the discrepancies of these lists, which probably contain the names of princes who reigned at the same time in the northern and southern divisions of the kingdom. The limits of the Pictish territories continued much the same till the middle of the 7th c., when a portion of the southern province was subdued by Oswy, king of Northumbria. In the beginning of the reign of Oswy's son and successor, Egfrid, the P. made an attempt to recover the territory which had been wrested from them. It was unsuccessful; and the power of the English was so firmly established, that the conquered province was erected into a diocese separate from Lindisfarne, the seat of the bishop being fixed at Abercorn. Encouraged by the success which had attended his enterprises, Egfrid seems to have contemplated the subjugation of the whole Pictish kingdom. He advanced northwards with his army; Brude, son of Bili, king of the P., retreating before him. The English sovereign passed the Tay, and the P. made a stand at Nechtansmere, supposed to be Duinichen, in Angus. A conflict ensued; the English were utterly defeated, and their king was slain. The consequences of this battle, which was fought on the 20th of May 685, were very important. The P. recovered the whole territory which they had lost, and even subdued for a time a portion of the proper Northumbrian kingdom.

The next Pictish prince whose name calls for special notice is Nectan, son of Derell, who succeeded about the year 710. He cultivated learning to some extent, and aspired to the position of an ecclesiastical reformer. The Pictish Church held precisely the same doctrines as the English; but it differed in various points of ritual, the most important of which related to the proper time of keeping Easter. The king applied for advice to Ceolfrið, Abbot of Jarrow, and the answer, which is addressed 'To the most Excellent Lord, and most Glorious King, Nectan,' is preserved among the works of Venerable Bede. Encouraged by this epistle, he summoned a council of his clergy and nobles, and enjoined them to observe the English usages. The royal command met with a ready obedience. He had also applied to the Abbot of Jarrow for architects to build a church of stone in the Roman fashion, which he proposed to dedicate to St. Peter. We are told by Bede that the architects were sent, but have no further information on this interesting subject. The plans of the king were probably interrupted by dissensions among his people; and the entire assimilation of the ecclesiastical institutions of Northern Britain to those of England was postponed for four centuries.

The most active of all the Pictish sovereigns was Hungus, son of Urgust, who succeeded in 730, and reigned for thirty years. He was engaged in constant wars with the Scots, the Britons, and the English, in which he was generally victorious. After his death, the kingdom began to decline. The history of its latest period is involved in impenetrable obscurity; all that we know for certain is the final result. Various princes claimed the crown, and held possession of portions of the kingdom. But the most powerful competitor was Kenneth, son of Alpin, king of the Scots, who was descended, in the female line, from the ancient sovereigns of the P., and was probably the true inheritor, according to the peculiar law of succession which is said to have existed among that nation. Kenneth was acknowledged as king in 843, and fixed his residence at Forteviot in Stratherne, the capital of the Pictish kingdom.

A famous passage from Henry of Huntingdon has often been quoted, in illustration of the supposed utter destruction of the P., of their princes, their race, and their language. It is referred to in that sense at the close of the following sentences of a work written some time before, but only published in the year 1864. 'The Pictish vessel is seen in the distant horizon; she approaches rapidly, till you clearly distinguish the crew upon the deck; but before you are near enough to hear their voices, she sinks, the waters close over her, and the wreck never can be raised. The total extinction of the Pictish language renders any further inquiry impossible. The acumen and criticism of the 19th century cannot advance beyond the homely wisdom of the 12th century.'—Sir Francis Palgrave's *History of Normandy and England*, vol. iv. p. 294.

The impression conveyed by such words is an erroneous one. The Pictish princes still continued to reign in the persons of Kenneth and his descendants. They were kings of the P. in reality and by race, as much as James I. and his successors were kings of England. The princes did not cease in the one case more than in the other to be sovereigns of the larger kingdom, because they had previously ruled in the lesser one. Neither did the nation of the P. cease to exist. They dwelt as before in their own land; their old capital was the capital of the new kingdom; and Pictavia is spoken of by the chronicles long after the accession of Kenneth, and long before Scotia became identified with Northern

Britain, or ceased to be the ordinary name for Ireland. Undoubtedly, through the influence of the kings, and perhaps of the clergy, whom the later Pictish princes had held under an oppressive bondage, the Scots became the predominant race, and finally gave their name to the united kingdom and nation. Neither did the language of the P. cease to be spoken. It continued, as before, to be the dialect of the north-eastern provinces, till, first in the extreme north, it yielded to the Scandinavian invader, and afterwards—more than two centuries subsequently to the accession of Kenneth—it began to recede slowly before the Teutonic tongue of English and Flemish colonists.

The same process which destroyed the Celtic language of the Pictish people, destroyed also the Celtic language of the British kingdom of Cumbria. The subject of the Pictish language has been of late thoroughly discussed by Mr. Skene in his *Four Ancient Books of Wales*. In addition to *Peanfahel*, the sole Pictish word formerly known, Mr. Skene has discovered four other distinct words, besides a number of syllables entering into proper names; and from all these he deduces the opinion that Pictish 'is not Welsh, neither is it Gaelic; but it is a Gaelic dialect partaking largely of Welsh forms.' More specifically, he holds that Pictish, as compared with Gaelic, was a *Low* dialect—that is, differed from Gaelic in much the same way that Low German differs from High.

The chief ancient authorities for the history of the P. are Adamnan's *Life of St. Columba*, edited by Dr. Reeves; the *Ecclesiastical History of Venerable Bede*; the *Life of St. Ninian*, by Ailred of Rievaulx, in Pinkerton's *Ancient Lives of Scottish Saints*; the Pictish Chronicle, in the appendix to Innes's *Critical Essay on the Ancient Inhabitants of Scotland*, and in the appendix to Pinkerton's *Inquiry into the History of Scotland*; and the *Irish Annals*, edited by O'Connor. The best modern works on the subject are Innes's *Critical Essay*, and his *Civil and Ecclesiastical History of Scotland*; Pinkerton's *Inquiry*; Chalmers's *Caledonia*, vol. i.; Ritson's *Annals of the Caledonians, Picts, and Scots*; Mr. Grub's *Ecclesiastical History of Scotland*, vol. i.; a dissertation in Garnett's *Philological Essays*; and Mr. W. F. Skene in his *Four Ancient Books of Wales*; and in *Celtic Scotland* (2 vols., 1875—1877).

PICTS' HOUSES, the name popularly given in many parts of Scotland to the rude underground buildings, more commonly and accurately called *EARTH-HOUSES* (q. v.). The name is often

Pict's House at Kettleburn, Ground plan.

given also to a more advanced class of buildings of the same kind, found in the more northern counties of Scotland. The ground-plan of one of these at Kettleburn, in Caithness, explored and described by the late Mr. A. H. Rhind, of Sibster, is figured in the accompanying woodcut. The outmost circle represents the extreme limits of the mound which covered the structure; *a*, a bounding wall, three feet thick, and three feet high, rudely built of large unshaped stones; *b*, an inner wall, four or five feet high; *c* and *d*, fragments of walls faced outwards; *e* and *f*, passages leading to the inner chambers; *g*, *h*, and *i*, passages leading to smaller side chambers; *k*, a wall within the wall of the chamber *s*; *m*, a chamber, so ruined that its walls could not be traced all round; *n*, a large boulder, which, being difficult to remove, had been built over; *o*, a chamber containing a regularly built well (between *p* and *p*), nine feet deep, and roofed over. The whole walls were built without mortar. The objects found within them were remains of animals and shell-fish, fragments of pottery, and implements of stone, bone, horn, bronze and

iron. The name of Picts' Houses is also occasionally given in the north of Scotland to rude stone structures above ground.

PICTURES are now protected by the law in a manner similar to books, the copyright of which belongs to some individual. By the act of 25 and 26 Vict. c. 68, if the author of any painting, drawing, or photograph in which there shall be subsisting copyright, after selling the same, or if any one, without the consent of the proprietor for the time being, repeat, copy, colorably imitate, or otherwise multiply for sale, hire, exhibition, or distribution, or cause this to be done, or knowingly import into the United Kingdom, or sell, &c., such copies, he shall forfeit to the proprietor of the copyright a sum not exceeding £10, and the copies and materials shall belong to such proprietor. Moreover, if any person affix a mark, monogram, or initials of a person who did not execute or make such work, to paintings, drawings, or photographs, or fraudulently sell, exhibit, or offer such for sale, such person shall forfeit £10, or double the price of the thing sold, &c., and all spurious copies and imitations become forfeited to the real owner. This statutory protection to artists and owners of pictures, engravings, and photographs extends to the United Kingdom.

PI'CUS AND PI'CIDÆ. See WOODPECKER.

PIE, a well-known culinary preparation, consisting of a crust of dough or pastry, enclosing either meat or fruit, and baked in the oven. The origin of the word is very obscure. There are two kinds of pies, one in which a dish is used, as in cases where much juice or gravy has to be retained; the other, without the dish. The latter are called raised pies, and a particular kind of paste is required; which is made with hot lard and water, and must have sufficient consistency to stand up. When moulded into the form or case of the pie, it is filled with meat, usually game, and baked. This kind of crust is not usually eaten, with its contents as it is considered unwholesome, it therefore merely serves as a case for the enclosed viands.

PIEDMONT, or PIEMONT (Fr. *piéd*, foot, *mont*, mountain), an Italian principality, which now forms the north-west part of the kingdom of Italy, is enclosed mostly by natural boundaries, having on the N. the Pennine Alps, on the W. the Graian and Cottian Alps, on the S. the Maritime Alps and Genoa, and on the E. the Ticino and the duchy of Parma. It includes the former duchy of Montferrat, which lies in its south-eastern corner, what was the Sardinian portion of the old duchy of Milan, and contains 11,750 English square miles, with a population (1881) of 3,070,379. The mountain ranges which form its boundary on the north, west, and south, attain, in various places, a great elevation above the sea; the Col de Tende, Monte Viso, Mont Cenis, Mont Iseran, Mont Blanc, Mont St. Bernard, Mont Cervin, Monte Rosa, and the Simplon, being all on the boundary-line. As to its general character, the country is partly mountainous, partly hilly, and much diversified with hill and dale; the ranges which traverse the country being spurs from the alpine boundary, and converging towards the central tract, through which flow the Po and its chief tributary the Tanaro. The valleys which separate these ranges are all watered by rivers which take their rise in the Alps, and pour their supplies into either the Po or the Tanaro according as they come from the north and west, or from the south. The amount of the water-supply in the country may be imagined when it is considered that in P. the Po receives no fewer than 10 tributaries on the left, and 6 on the right, all of them of considerable size, and some of them, as the Tanaro and Dora Batea, worthy of being classed as rivers. The valleys of the Po and Tanaro are exceedingly rich and fertile, producing abundant crops of grain, pulse, hemp, chestnuts, olives, and many kinds of fruit. Maize and barley are the chief cereals, the former being the ordinary article of food to the inhabitants, while abundant herds of swine are fed upon the latter. The climate is mild in winter; but in summer, especially on the level country east of the Dora Baltea and the Tanaro, the heat is scorching, and this portion would be rendered a perfect sandy desert, were it not for the complete system of irrigation, which supplies moisture to more than half a million of acres, and renders the eastern districts the granary of the country.

So valuable is the privilege of using the water of rivers as a means of irrigation, that a considerable tax is levied upon it. The other products of P. are wine and silk, which are produced in great abundance, especially silk, which is the best in Italy, and is generally exported raw. The chief manufactures are silk, linen, woollen, and cotton goods, hosiery, paper, leather, cutlery, various fermented liquors, glass, and iron. The inhabitants are active and industrious, and mostly belong to the Roman Catholic religion, but are more tolerant than in other parts of Italy. The Vaudois or Waldenses (q. v.), have from time immemorial inhabited the wild vales at the foot of the Cottian Alps, in the western corner of the principality. Many of the Piedmontese, like the Swiss and Tyrolese, spend their youth and early manhood in traveling through other countries as dealers in engravings, jewelry,

and other articles of merchandise, and returning with a small hoard, spend the rest of their days in comfort in their native land.

P., in the 10th c., was possessed by the marquises of Susa, Ivrea, Montferrat, and Saluzzo; and it was not till when, a century afterwards, the marquise of Susa passed into the House of Savoy, that the latter, then counts of the Maurienne (the south portion of Savoy), gained a footing in the country. At the commencement of the 12th c., the possessions of the House of Savoy were divided, and the lines of Savoy and P. formed; but they were again united, in 1416, by Amadeus VIII. (afterwards Pope Felix V.), who, in the following year, obtained from the Emperor Sigismund the title of Duke of Savoy, which they exchanged for that of king in 1684. During the Spanish War of Succession, P. was increased by the addition of the provinces of Alessandria, Valence, Lomellino, and the Val di Sesia (1703), by Tortona and Novara in 1735—1736, and by Vigevanese and Bobbio in 1743. In 1796, it was seized by the French, and parcelled out into six departments, five being incorporated with France, and one with the kingdom of Italy; but after the fall of Napoleon, the House of Savoy recovered possession of it. See ITALY, SARDINIA, SAVOY. Since 1860, the name P., as a provincial designation, has been disused; and P. proper is now divided into the provinces of Alessandria, Coni or Cuneo, Novara, and Turin.

PIEDIMONTÉ D'ALIFÉ, a town of South Italy, 20 miles north-by-east of Caserta, at the base of the Apennines. Cotton-mills employ 1500 hands. There are copper-mines in the vicinity. Pop. about 6000. Piedimonte is the name of several smaller towns and villages in Italy and Sicily.

PIE'DRA BLANCA, a town of the Argentine Republic, South America, 20 miles south-west from Catamarca. Pop. 10,000.

PIE'POWDER COURT, in England, an ancient court held in fairs and markets to administer justice in a rough and ready way to all comers, called also the Court of Dusty Foot (Fr. *piéd poudreux*). Its jurisdiction seems to have been confined mostly to petty vagabonds, pedlars, and other wanderers. The court has long been obsolete, the only jurisdiction of that kind being now merged in the court of Petty Sessions (q. v.).

PIER, the block of solid wall between doors, windows, &c.; also a solid mass of masonry built to receive the arch of a bridge. The term is also used synonymously for the Pillars (q. v.) of a church; thus we speak of nave-piers, &c.

PIERCE, FRANKLIN, the fourteenth President of the U. S. of America, was born in Hillsborough, New Hampshire, November 23, 1804. His father, General Benjamin Pierce, was a soldier of the war of independence, and governor of New Hampshire. Franklin P. was educated at Bowdoin College, Maine, and was an officer in a college military company, in which his biographer, Nathaniel Hawthorne, was a private. He spent his first vacation in teaching a country school, studied law with Levi Woodbury, governor and senator, was admitted to the bar in 1827, became speaker of the State House of Representatives in 1829, and was elected to the 33d congress, a democrat of the school of Jackson. In 1837, he was elected to the U. S. senate, of which he was the youngest member. He declined the office of Attorney-General offered him by President Polk, and refused the nomination for governor of New Hampshire; and at the commencement of the Mexican war, volunteered as a private, but was appointed brigadier-general, and led his brigades in the battles of Contreras and Churubusco.

In 1852, in consequence of the conflicting claims of the leaders of the Democratic party at the Baltimore Convention, he was nominated as a compromise candidate for the presidency, against General Scott, the Whig nominee, and received the votes of all but four states. He appointed an able cabinet, including Jefferson Davis as Secretary of War. During his administration, the Missouri Compromise was repealed; the treaty for reciprocity of trade with the British American colonies was made, and a treaty with Japan; and the Kansas difficulties which then arose, with the growing animosity between the North and South, led to secession, and the war of 1861. At the close of his term of office in 1857, he traveled in Europe, and, having no sympathy with the party which subsequently came into power, he took no part in politics. He died in 1869.

PIERCED, in Heraldry, a term used to indicate that a charge is perforated so as to show the field beneath it. The aperture is presumed to be circular, unless some other form, as square-pierced or lozenge-pierced, be specified in the blazon.

PIERRE, JACQUES HENRI, BERNARDIN DE ST., a celebrated French writer, was born at Havre, 19th January 1737. He received his education at Caen and Rouen, and afterwards entered the government department of civil engineers. On his dismissal from this service in 1761, he wandered about the continent for several years, endeavoring to realize his dream of a republican colony. He returned to France in 1766, and soon after obtained

a commission as engineer for the Mauritius; but after a residence of three years in the island, he returned to Paris. At this time he wrote the story of *Paul et Virginie*. The little book, with its passion, its simplicity, its tenderness, achieved an immense success, and has been translated into almost every language. St. P. passed through the storms of the Revolution in safety, and was lucky enough to secure the patronage of Napoleon. He died 21st January 1814. Besides *Paul et Virginie*, he wrote other tales, essays, and several plays.

PIERS PLOWMAN, or rather *The Vision of William concerning Piers the Plowman*, is a remarkable poem by William Langland or Langley, who was born, apparently in Shropshire, about 1332, was educated for the church, and died in London near the end of the century. The *Vision*, a powerful poem in vigorous alliterative verse, describes a series of nine dreams, in certain of which a person called Piers the Plowman appears. Under allegorical covering, the *Vision* exposes the manifold corruptions of the state, of the church, and of existing social arrangements. From the forty-three MSS. which remain, it is evident that the poem, originally written about 1362, was repeatedly revised, altered, and extended, and that it continued to occupy the author all his lifetime.

PIETÀ' (an Italian word signifying *piety*, in the sense in which that term indicates or includes affection for relatives), the name given in the language of art to representations of the Virgin Mary embracing the dead body of her son. It is a counterpart to the *Madonna* with the infant Jesus in her arms. The one affords an opportunity for the representation of the purest joy and highest motherly love; the other of the utmost pain and grief. The *pietà* has long been a favorite subject, not only with painters, but with sculptors.

PIETERMARITZBURG, capital of Natal (q. v.), 50 miles from the coast. Pop. about 7000.

PIETISTS, a designation given since the end of the 17th c. to a religious party in Germany, which, without forming a separate sect, is distinguished not only by certain peculiarities of religious opinion, but also by the manner in which these are manifested. The peculiar character of their religion is very generally denoted by the term *pietism*, which is frequently employed with reference to the same tendencies of opinion, feeling and conduct, whosoever and whencesoever exhibited. Pietism may be regarded as consisting in an exaltation of the importance of religious feeling, and of the practical part of religion, with a corresponding depreciation of doctrinal differences, and a contempt for outward ecclesiastical arrangements; and has been more or less strongly developed from time to time in all sections of the church, a tendency towards it always existing in a large class of earnestly religious minds.

In the church of the middle ages, this tendency was displayed in an endeavor to attain to a superior spirituality and purity by means of a religious contemplation and asceticism, and many, consequently, embraced a monastic life. The Reformers, adopting the Augustinian doctrines, rejected this mode of seeking deliverance from indwelling sin, and proclaimed the efficacy of faith in the sacrifice of Christ. But the controversies which arose among them, and increased among their successors, gradually gave a too exclusively doctrinal and polemical character to the sermons and writings both of the Lutheran and Calvinistic divines, particularly in Germany, and a reaction ensued, not in favor of the Church of Rome, but in favor of a religion of feeling and good works, or of the heart and life. Disgust at the sectarian bitterness and exclusiveness which prevailed, led even to an undervaluing of disputed points; and thus the *Pietism* of Germany was generated and developed. The origin of it is referred to a work entitled *Vom wahren Christenthume*, by John Arnd, published in 1605; to the *Institutio Fraternalitatis Christi* of John Val. Andreæ, published in 1617, both of them Lutherans; and to the writings of Cocceius, a Calvinist. But its fuller development is unquestionably to be ascribed to Spener (q. v.), in the latter part of the 17th c., and to his friends and disciples. The name *Pietists* was first given in contempt to certain young *docents* in Leipzig, who began in 1689 to give prelections on the New Testament both to students and citizens, and to addict themselves much to a meditative mode of life. Spener had held meetings of a somewhat similar kind in his own house when preacher at Frankfurt-on-the-Maine, and in his writings had urged the necessity of a reform in the Protestant church and theology. He and his followers dwelt much upon the importance of studying the Scriptures rather than the symbolical books, upon the unfitness of any unconverted or unregenerated person for the office of the ministry, upon the right and duty of the laity to take part in the exercises of Christian assemblies, and upon the necessity of a practical rather than a systematic religion.

But many of the more extreme Pietists carried their antipathy to the doctrinalism and the established services of the church to a degree that alarmed the theologians of the old school, the high and dry Lutherans, or German 'moderates,' who accused Spener

and his disciples, not without reason of a tendency to make all goodness and virtue consist in mere religious feeling, or pious sentimentalism; to represent the divine grace as operating in too sudden and abrupt a manner; to exaggerate the value of good works; to depreciate the value of learning and of clear intellectual perception in the study of Scripture; and to indulge in a strictness of judgment upon the religious character of the ordained clergy, tending to sectarianism, and indeed incompatible with ecclesiastical unity. The weapons of argument, however, were not the only weapons employed against them. The docents were compelled to give up their prelections, and finally to leave Leipzig; the meetings for mutual edification were suppressed by the government as disorderly conventicles; and Francke (q. v.), the most distinguished of the Leipzig docents, having gone to Erfurt, was prevented from lecturing, and quickly compelled to retire. Spener's influence, however, procured a refuge for his friends in the newly founded university of Halle, and Francke obtained a professorship there. Halle became thenceforth the source of new religious influences, and, indeed, of a new religious life to Germany. The Pietists, although spiritually exclusive—disposed to regard themselves as the 'chosen of God,' and to look down on all others as 'children of the world,' or even of the devil—did not attempt to form a separate sect. To do them justice, they were as far as possible from being ecclesiastically ambitious; all their desire was to excel in 'labors of love,' and to cultivate feelings of intensest piety.

The rise of the Wolffian or Rationalistic theology, the spread of that sort of sceptical anti-clerical philosophy which flourished for a while under the name of *Aufklärung* (Enlightenment), exercised an injurious and depressing influence on Pietism; yet through all the long obstinate warfare maintained against the doctrines of the church by the Rationalists during the last half of the 18th, and the most part of the 19th c., Pietism continued to number some adherents; and it can hardly be doubted that it is to the Pietists, and not to the Lutheran dogmatists, that Germany is in a great measure indebted for that revival of religious faith and feeling which, begun with the great Schleiermacher—himself trained up under pietistic influences—has since widely diffused itself through her biblical scholars and theologians. The patriotic enthusiasm called forth by the insolent conquests of the French, naturally allied itself to pietistic tendencies, for in Germany, the triumphs of Napoleon even as emperor were looked upon as the triumphs of revolutionary, republican, and infidel principles; and after the general restoration of peace, the statesmen and upper classes, especially in Prussia, believing that political security could only be obtained by a return of the populace to the simple, obedient, and unquestioning piety of earlier times, countenanced this party in the church; and amiable tea-drinking societies of devout men and women were formed to distribute tracts, and to inculcate the radical and heathen masses with pietistic sentiments. But this attempt to use 'piety' for reactionary political purposes sullied its purity, and alienated from it the very parties whom it wished to influence. Still, however, Pietism exists as a distinct element in the religious life of Germany, and now, as ever, its strongholds are Prussia (Berlin, Silesia, Wuppertal), Hesse, and Württemberg.

PIE'TRA-DU'RA, a name given to the finest kinds of Florentine mosaic-work, in which the inlaid materials are hard stones, such as jasper, carnelian, amethyst, agate, &c. The real *pietra-dura* work dates as far back as the 16th c., about 1570; and from that time to the present, has been almost confined to Florence, where a government *atelier* has existed ever since the beginning of the 17th c., which was originated in order to supply decorations for the Capella Medicea. It is sometimes called *Pietre Commesse*, and *Lavoro di Commesso*. In the inferior kinds, which are sold in Italy, and are manufactured now pretty extensively in Derbyshire and other parts of Britain, pieces of colored sea-shells are used instead of the harder and more valuable colored stones.

PIETRAPE'NZIA, a town of Sicily, six miles south-east from Caltanissetta, on a lofty height. Pop. 10,000.

PIEZO'METER (Gr. *piezo*, I press; *metron*, a measure), an instrument for measuring the compressibility of fluids. Oersted's (q. v.) instrument, the first by which the compressibility of water was satisfactorily determined, consisted of a cylindrical glass jar, into the neck of which a narrower cylindrical tube of glass, open at both ends, was firmly fixed. In this tube worked an air-tight piston by means of a screw. In the interior of the jar was placed a bottle, whose neck was drawn out into a long capillary graduated tube, and alongside this bottle was suspended a cylindrical tube, closed at the top, but open at the bottom. When the compressibility of any liquid was to be determined, the instrument was adjusted in the following manner: the bottle inside was filled almost to the top of the capillary tube with the fluid, and being replaced inside the jar, the latter was completely filled with water up to the piston in the neck. The liquid in the submerged bottle, then under pressure of the water above it, fell slightly in

the capillary tube, being kept from contact with the water by an air-bubble, the motion of which up or down, according as the pressure was less or greater, served as an index for reading off the graduation. The suspended tube alongside being at first only filled with air, the water rose in it to some extent, and by graduations on the tube it was made to indicate the pressure in atmospheres or parts of atmospheres.

Pressure was now applied to the water in the jar by screwing down the piston; the compressed water communicated the pressure to the liquid in the bottle and to the air in the suspended tube; the descent of the air-bubble in the former indicating the amount of diminution in bulk the liquid had undergone (the capillary tube being graduated in inches and parts of inches, and each inch of tube being known to contain a certain fraction of the contents of the bottle), while the ascent of the water in the suspended tube showed the amount of pressure which had been applied.

PIG. See HOG.

PIGEON (Ital. *pigione*, *piccione*, or *pipione*, from *pipiare*, Lat. *pipire*, to peep or cheep), a name sometimes applied, like Dove (q. v.), to all the species of *Columbidae* (q. v.), and sometimes almost restricted to those still included by ornithologists in the genus *Columba*; having a bill of moderate length, hard, and a

1. Ring Dove, Cushat, or Wood-pigeon; 2. Biset, or Wild Rock Pigeon; 3. Collared Turtle.

little arched at the point, the base of the upper mandible covered with a soft thick skin, in which the nostrils are pierced; the feet with toes divided to the base, and formed both for walking and perching; the wings rather large and pointed; the tail of moderate length, and generally square at the end. The species of this group are numerous, and occur in almost all parts of the world. Some of them build their nests in trees, and some in holes of rocks; they lay only two eggs at a time, but breed twice or oftener in a year, and both the male and the female take part in incubation. The original of all the varieties of the DOMESTIC P. is now almost universally believed to be the ROCK P. or ROCK DOVE (*C. livia*), the *Biset* of the French, a bird of extensive geographical range, being found as far north as the Farøe Islands, and on many parts of the coasts of Europe, Asia as far as Japan, and the north of Africa, breeding in crevices of rocks, and often within caverns which open on the sea. It swarms in prodigious numbers in some of the rocky islands of the Mediterranean; and even on the British coasts, great numbers are found in some localities, particularly in the Orkneys and Hebrides. Its food consists partly of molluscs and other small animals, partly of grain and seeds; and it often makes unwelcome visits to the corn-fields of its vicinity.

In a wild state, this bird exhibits great uniformity both of size and plumage; being not quite twelve inches in length from the tip of the bill to the end of the tail; the prevailing color bluish-gray, in some parts with green and purple reflections, two broad and distinct bars of black across the closed wings; the lower part of the back white; the tail deep gray, with a broad black bar at the end; the bill blackish-brown; the legs and toes reddish-orange.—Until recently, naturalists very generally confounded this species with the STOCK DOVE or SMALLER WOOD P. (*C. oenas*), a species which inhabits woods, and generally builds in trees, preferring the hollows of old decaying trees or the tops of such as have been pollarded and have become bushy—whence the

name *Stock Dove*. In some of the open parts of England, however, it makes its nest in rabbits' burrows or other holes in the ground. It is rather larger than the Rock P.; its prevailing color is bluish gray, in some parts passing into pale gray, but nowhere into white; the wings destitute of bands; the sides of the neck with green reflections; the breast purplish red. It congregates in large flocks in autumn and winter. It is partially migratory in some parts of Europe; a summer visitant of the northern regions. In Britain, it is found only in the southern parts of the island. Its geographical range includes great parts of Europe and Asia, and the north of Africa. It feeds on beech-mast, acorns, grain, pulse, &c., and sometimes resorts to turnip-fields to eat the tender tops. Its voice is very different both from that of the Rock Dove and that of the Ring Dove.

Its flesh is of very fine flavor.—The RING DOVE, WOOD P., or CUSHAT (*C. palumbus*), is the most common British species, and is diffused over great part of Europe, either as a permanent resident or a summer bird of passage, although it is not found at all in some of the most western regions; and occurs also in the temperate parts of Asia, and the north of Africa. Its soft loud *coo* is one of the pleasant intimations of the approach of spring. It inhabits woods, and builds its nest among the branches of high trees. It is the largest of the British species, being about seventeen inches in entire length. It feeds on green corn, young clover, turnip-tops, grain, pulse, acorns, &c. Where it abounds, its voracity is often very injurious to the farmer. It is gregarious in winter. It is inconsiderable estimation as an article of food; but it is very shy and wary, not easily approached by an inexperienced sportsman.—These are all the British species of pigeon. Our limits quite preclude us from noticing almost any other. The RING-TAIL P. (*C. caribbea*) may be mentioned as a West Indian species, much valued for the richness and delicacy of its flesh, which is reckoned one of the greatest luxuries of that part of the world. The BALL-PATE or WHITE-HEADED P. (*C. leucocephala*) is another large and fine species plentiful in the West Indies. It migrates to the Keys of Florida in summer.—The DOUBLE-CRESTED P. (*C. dilophia*) is a large species, inhabiting the north of Australia and warmer regions to the northward, remarkable for its crest, which consists of two parts, one on the back of the head, and another of lax recurved feathers springing from the forehead, and even from the base of the bill.

Only one species of P. has been truly domesticated, and having long been so, it has undergone many remarkable changes, and there are numerous varieties or breeds; some of them, exhibiting very strange peculiarities, and known as *fancy pigeons*, being carefully preserved and tended by pigeon-fanciers. Pigeon-fancying is nowhere carried further than in London, where there are many persons who give great part of their time to it, and whose pigeons are their chief delight. The prices of such fancy pigeons as are deemed most perfect of their kind, are very high. The ordinary domestic pigeons, kept for profit as a kind of poultry, differ from the wild rock dove chiefly in color, in which they are often very unlike it, although a tendency always manifests itself to return to the original colors, and the bars on the wings are apt to reappear in the progeny even of what may be called the most artificial varieties. Of these may be mentioned, as among the most interesting, the Rough-footed P., having the feet feathered; the Jacobin, which has a range of feathers inverted over the head, and extending down each side of the neck, as a hood; the Fan-tail, or Fan-tailed Shaker, in which the number of the tail-feathers is greatly increased, and the bird has the power of erecting its tail like that of a turkey-cock, whilst it has also a peculiar vibratory motion; the Tumbler, so called from tumbling in the air in its flight, and further characterized by a very short bill; and the Pouter or Cropper, which has the power of blowing up its crop to an extraordinary degree, so that the head seems fastened on the top of an inflated bladder. The Carrier P. (q. v.) is regarded as a variety of the Common Pigeon.

The law regarding pigeons is stated in the article DOVECOT. For the profitable keeping of pigeons, it is necessary to have a properly-constructed dovecot, divided into cells, a cell for each pair, each cell sixteen inches broad, by twelve from front to back, and the door towards one side, so that the nest may not be seen from without; a slip of wood in front of each cell for the birds to sit and coo on. The dovecot must be placed at such a height as to be out of the way of rats and other depredators; and must be frequently cleaned, otherwise it may probably be deserted by its occupants. It ought to be painted white, that color being very attractive to pigeons, and contributing to retain them when a new dovecot is established, in which there is often found to be not a little difficulty. Pigeons begin to breed at the age of nine months, and breed every month except in very cold weather. The male and female continue faithful to each other from year to year, a circumstance noted by Pliny and others of the ancients, and evidently, as well as their somewhat demonstratively manifested affection, a reason of the poetic references often made to the dove.

PIGEON PEA (*Cajanus*), a genus of plants of the natural order *Leguminosæ*, suborder *Papilionaceæ*, of which, according to some botanists, there is only one species (*C. flavius*), a native of the East Indies, but much cultivated also in the West Indies and in Africa; according to others, there are two species, *C. flavius*, with flowers entirely yellow, the pod marbled with dark streaks, and two or three seeds in each pod; and *C. bicolor*, called **CONGO PEA** in the West Indies, the pulse of which is much coarser, and is used chiefly by negroes. The finer kind is nearly equal to the Common Pea. This kind of pulse is very much used in tropical countries. The plant is a shrub (*Cytisus cajan* of Linnæus) about eighteen inches high. It is half-hardy in the south of England. In tropical countries, the plants stand and are productive for several years. They throw off their leaves annually, and reproduce them along with their flowers. The P. P. is one of the most valuable of the tropical kinds of pulse. It grows either on rich or poor soils. It is called *Doll* and *Urthur* in the East Indies. The name P. P. is West Indian.

PIGMENTS. See **PAINTS**.

PIKE, PIKEMAN. Previously to the use of the bayonet, infantry of the line of battle—that is, the heavy-armed troops—were from the earliest times armed with pikes or spears. The Macedonians carried pikes 24 feet long; those of modern warfare averaged 12 or 14 feet. They were of stout wood, and tipped with a flat iron spearhead, which sometimes had cutting edges. As a defence against cavalry, the pike, from its length and rigidity, was of great value; but though it long survived the introduction of gunpowder, that event was really fatal to it. For success with the pike, especially in offensive war, a depth of several men was essential, and this depth rendered the fire of artillery peculiarly fatal. The pike is now superseded by the bayonet on the end of the musket.

PIKE (*Esox*), a genus of malacopterous fishes, including all the species of the family *Esocida*, as restricted by Müller, and characterized by an elongated body, covered with scales, a depressed head, and broad blunt muzzle, with very large mouth, abundantly furnished with teeth of various sizes on the jaws, palatine bones, and vomer; no adipose fin; and the dorsal fin placed very far back over the anal fin. The species are not numerous; they are all inhabitants of fresh waters in the northern hemisphere. Only one is found in Europe, the **COMMON P.** (*E. lucius*), a native also of Asia and North America. It is very generally diffused over Europe, and is abundant even in its most northern regions; and is now abundant in lakes, ponds, and slow rivers in all parts of the British Islands, although it is supposed not to be truly indigenous to them, but introduced. The statement, which has been often made, however, that it was introduced in the reign of Henry VIII., is certainly erroneous, as there is evidence of its existence in England at a much earlier date. Edward I., graciously regulating the price of commodities for his subjects, fixed the price of the pike higher than that of the salmon, and ten times higher than that of the turbot and the cod, from which we may perhaps infer its comparative rarity at that period. Some of the waters in the fenny districts of England are peculiarly adapted to pike, which are there found in very great quantity, and of superior quality.

The P. is of a dusky olive-brown color on the upper parts, becoming lighter and mottled with green and yellow on the sides, and passing into silvery white on the belly; the fins brown; the larger fins mottled with white, yellow, and dark green. The tail-fin is forked. The P. grows to a large size, occasionally attaining a weight of sixty or seventy pounds, although the stories of pikes much larger than this are liable to suspicion. The excessive voracity of the P. has long been proverbial. No animal substance which it can swallow, and which is capable of being digested, seems to be unpalatable to it; and no animal large enough to attract its attention, and which it can master, escapes being devoured. Mr. Jesse mentions an instance of eight pike, of about

kept it in his mouth for about a quarter of an hour before swallowing it. The P. readily attacks a fish of its own size, and preys freely on the smaller of its own species. Frogs are frequent prey; water-rats and ducklings are sometimes devoured. A large P. often takes possession of a particular hole in the bank of a river, from which it issues to seize any creature that may pass.—The P. spawns in the beginning of spring, for that purpose ascending narrow creeks and ditches, in which it is very easily caught by nets. Large quantities are caught at the spawning season in Lapland, and dried for future use. The P. grows very rapidly when the supply of food is abundant, reaching a length of 8 to 10 inches in its first year, 12 to 14 in the second, 18 to 20 in the third, and afterwards increasing for a number of years at the rate of about four pounds every year. A young P. is sometimes called a *Jack* or *Pickereel*. The name *Luce* (Lat. *lucius*) is still known as an English name of the pike. The Scotch name is *Gedd*, a name similar to those in the Scandinavian languages. The flesh of the P. is much esteemed, but that of pikes of moderate size is reckoned superior to that of small, or of very large ones.

The P. is not only caught by means of nets, but by the rod, by set lines, and by *trimmers* or *liggers*, which may be briefly described as floats with lines attached to them, the line being so fastened that the bait swims at a proper depth, and that some yards of line run out when the bait is taken. The floats are sometimes made of wood or cork, sometimes of bundles of rushes, sometimes of bottles. In angling for P., various baits are used, such as a minnow, par, or other small fish, a portion of a fish, &c., and sometimes an artificial fly is employed with great success,

Pike Spinner.

made of two large hooks tied together, and adorned with two *moons* from a peacock's tail. The angler unaccustomed to the P. must be cautioned as to the manner of the taking the hook from its mouth, as any rashness may lead to severe laceration of his hand by its teeth. P. may be fished any time from May to February inclusive, except when it is actually freezing. The best month is considered to be November; the P. are then in the best condition. One of the most approved tackles for angling for the P. is the *Spinner*, baited with a small dace, bleak, gudgeon, or par of about two ounces, as represented in the figure given above. The mode of using it is thus described in Bailey's *Angler's Instructor*: 'Having cast your bait as far as possible, allow it, if you are fishing in a pond, or lake, or deep water, to sink a little, say two feet, then wind away at a brisk rate, holding your rod on one side rather low; if no run, wind out and throw again, but this time wind brisk four or five yards, then all of a sudden stop a moment, then off again, doing so three or four times in one cast. I have often found this a good plan. If you still have no run try another throw and wind brisk as before, but occasionally giving your rod a sharp but short twitch.' See also Stonehenge's *British Rural Sports* (London, 1875).

Other species of P. are found in the lakes and rivers of North America, as *Esox estor*, which is sprinkled with round blackish spots, and *E. reticulatus*, which is marked with a net-work of brownish lines.

The Gar-fish (q. v.) is sometimes called the Sea Pike. The same name is also given to certain large voracious fishes of warm seas, belonging to the perch family.—The Saury P. is noticed in a separate article.

PIKE-PERCH (*Lucioperca*), a genus of fishes of the perch family, having two dorsal fins, of which the first has strong spiny rays, but resembling the pike in its elongated form, large mouth, and formidable teeth. The muzzle is not, however, broad and depressed, as in the pike. Several species are known, of which one (*L. sandra*) is common in the Danube, and in most of the rivers and lakes of the north-east of Europe, extending westward to the Oder and the Elbe, although not found in Italy, France, or Britain. It is highly esteemed for the table, and its introduction into British rivers seems particularly desirable. Salted and smoked, it is a considerable article of trade in some parts of Europe. It is a fish of rapid growth, and attains a weight of 25 or 30 pounds. The fish readily takes the minnow and the artificial fly. It is called *Sander*, *Sandel*, or *Sandat*, in some parts of Germany; *Nagmarul* in Bavaria; and *Schill* at Vienna.—Another species (*L. Americanus*), much resembling it, of a greenish-yellow color, is found in the lakes and rivers of North America.

Pike, or Jack (*Esox lucius*).

five pounds' weight each, consuming nearly 800 gudgeons in three weeks; and one of them devoured four roach, each about four inches in length, in rapid succession, and seized the fifth, but

PIKE'S PEAK, a peak of the Rocky Mountains, Colorado, U.S., 75 miles south of Denver (q. v.), discovered by General Pike, U.S.A., in 1806. Its height is 14,151 feet, and it commands a view, of 100 miles' radius, of a rugged, mountainous country, containing many lakes, and the sources of four great rivers—the Platte, Arkansas, Rio Grande, and Colorado of California. In 1858, large deposits of gold were discovered here; and during the first four years after the discovery, there were shipped more than £6,000,000 in gold. It abounds in rich gold-bearing quartz. The mining country is 5000 feet above the sea, with a dry climate. An important high-level observatory, from which both meteorology and astronomy profit, has been established near the summit of the mountain.

PILA'STER, in Classical Architecture, a square pillar, sometimes standing free, but usually attached to a wall, from which it projects $\frac{1}{4}$ th, $\frac{1}{2}$ th, or other definite proportion of its breadth. Greek pilasters, or antæ, were of the same breadth from top to bottom, and had different capitals and bases from those of the orders with which they were associated. The Romans gave them a taper like the columns, and the same capitals and bases.

PIL'LAU, or **PILAW**, a dish common in India, Turkey, Egypt, and Syria, consists generally of rice, but occasionally some animal food is added. It is sometimes seen at tables in this country, prepared for those who have been accustomed to it abroad. The correct method of preparing it is to boil the rice for twenty minutes, with sufficient water to soak it thoroughly, and swell the grains to their utmost, taking care not to break them by making them too soft; it is then drained, and gently stirred with butter, pepper, and finely-chopped onions, and served up. This is the way in which the pilaws of the poorer classes are prepared; but for the tables of the more wealthy, fowls, lamb, mutton, shreds of ham or bacon, variously cooked, but always much broiled or roasted, are placed on the top of the rice, and served up with it. In India, very numerous and elaborate receipts are in use.

PIL'CHARD (*Clupea pilchardus*, or *Alausa pilchardus*), an important fish of the family *Clupeidae* (q. v.), referred by some naturalists to the same genus with the Herring (*Clupea*), and by others to the same genus with the Shad (*Alausa*). The P. is nearly equal in size to the herring, but rather thicker, and the lines of the back and belly are straighter; the scales are also larger and fewer; and the dorsal fin is rather further forward. The mouth is small, and in the adult fish destitute of teeth; the under jaw longer than the upper. The upper part of the body is bluish-green; the sides and belly silvery white; the cheeks and gill-covers tinged with golden yellow, and marked with radiating stripes; the dorsal fin and tail dusky.

The P. is an inhabitant of more southern seas than the herring. It used to be found most plentifully on the coasts of Devon and Cornwall, but has of late been deserting these seas; and now the Cornish fishermen ply their craft successfully off the Irish coast, near Skibbereen (where the season is July). The P. is also found on the coast of France, Spain, and Portugal. Like the herring, it was formerly supposed to be a migratory fish; but, as in the case of the herring, this opinion has now been relinquished; and the shoals of pilchards which are seen on the coasts are believed merely to issue from deeper waters near at hand, for the purpose of spawning. The spawning season of the P. begins early in summer; but on the coasts of Devonshire and Cornwall, the principal fishery is in August and September. Pilchards are caught either with drift-nets or sear-nets, but principally with sear-nets. By means of one or more sears, each 360 feet long and 36 feet deep, a shoal is enclosed; the bottom of the net is then drawn together by a peculiar contrivance, and the pilchards are taken out at low water by small bag-nets. Prodigious numbers are sometimes enclosed in a single sear. Twenty-four millions and a half are said to have been taken at once from a single shoal, which, however, may have been spread over several square miles. The approach of a shoal of pilchards is known by the rippling of the water, and the sea-birds hovering above, and is often watched for and marked from the shore. In some years the quantity taken in the P. fishery on the English coast is enormous, and the capital invested in it in Devonshire and Cornwall is probably not much under £1,000,000. The English P. fishery is regulated by several acts of parliament, the first of which are of the days of Elizabeth. Great quantities of pilchards are annually exported to the West Indies and elsewhere. Those intended for exportation are pickled, and packed in barrels by means of great pressure, by which oil is expressed to the amount of three or four gallons from a hog-head of fish. The oil, with the blood and pickle with which it is mingled, is generally used for manure. A favorite Devonshire dish is a pie made of pilchards, with their heads protruding from the crust. It is now generally admitted that the P. and the sardine are identical, and a Cornish Sardine Company has been started for preparing pilchards, like sardines, in oil. It is said that the Cornish sardines cannot be distinguished from those imported from France.—A great number of boats are employed

in the P. fishery in and near the estuary of the Tagus.—The P. is known in Scotland as the *Gipsy Herring*.

PILCOMAY'O, a river of South America, whose course has not as yet been thoroughly explored, draws its waters from the Bolivian Andes, and is formed by the confluence of two rivers, the Suipacha and the Pilaya. Of these head-waters, the south one, the Suipacha, rises in the mountains immediately south of Potosi; while the northern branch, the Pilaya, drains the valleys around Chuquisaca. These streams unite in lat. about 21° 35' S., to form the P., which flows in a general direction south-east crosses the Bolivian frontier, waters the north-east region of the Argentine Confederation, and falls into the Paraguay a few miles below Asuncion. It is at least 1200 miles in length; but its waters are much spent in lagoons on its course, so that it adds no great volume to the waters of the Paraguay. It is navigable for about 500 miles; but numerous hordes of hostile Indians render navigation perilous. Before entering the Paraguay, it divides into two arms of which the northern is called Araguay-Guasó; and the southern, which is again divided into two branches, the Araguay-Mino. The mouths of the P. are narrow, deep, and much obstructed by water-plants.

PILE, in Heraldry (from Lat. *pilum*, a javelin; or from the *pila* or stake used in the construction of a bridge), an ordinary, or, according to some heralds, a subsidiary, in the form of a wedge, issuing generally, as in fig. 1, from the middle chief, and extending towards the middle base of the shield. It is said that a pile should occupy one-third of the breadth of the chief, or, if charged, double that breadth. When a pile is borne issuing, not from the middle chief, but from some other

Pile.

part of the bounding-line of the shield, this must be specified in the blazon. Three piles are sometimes borne conjoined in point, as in fig. 2. A pile *transposed* is one whose point is upward.

PILE-BRIDGE, a bridge of which the piers are built with piles. These may be either temporary wooden structures, in which wooden piles, driven into the ground, serve also as piers, or they may be permanent bridges, with iron cylinders forming the piles below the surface, and piers above. See **PILES**.

PILES are usually squared logs of wood used in engineering operations, such as dams, bridges, roads, &c. They are sharpened at the point, and, if necessary, protected with iron points, to enable them to cut through the strata they encounter as they are driven into the ground. When used for coffer-dams, or such temporary purposes, they are placed close together, and driven firmly into the earth; the water is then pumped out, and the piles form a dam, to enable workmen to lay foundations of piers, &c. When the force of the water round the dam is great, two rows of piles are driven in all round, and the space between the rows filled with clay, and puddled. Piles are also used for permanent works, when they are driven through loose soil till they reach a firm bottom, and thus form a foundation on which buildings, roads, &c., may be placed.

Cast iron is frequently used for piles, which are cast hollow. Wharf-walls are sometimes built of piles; they are then cast with grooves on the sides, into which cast-iron plates (forming the walls) are fitted.

A kind of pile has been invented by Mr. Mitchell, which is of great use in very loose and shifting substances. It is called the screw-pile, and consists of a long shaft (of wrought iron), with a broad cast-iron disc, of a screw form at the lower end. These piles are especially useful for light-houses, beacons, &c., which have to be placed on sands. They are fixed by means of capstans, which give them a rotatory motion. Common piles are driven in by machines called *pila-drivers*. In these, a heavy weight (or monkey) is raised to a considerable height between two guides, and then let fall on the head of the pile. The application of steam to these drivers has made them very powerful engines—Nasmyth's steam-hammer being a well-known instance.

In 1843, Dr. L. H. Potts obtained a patent for a new kind of pile, which consists of hollow tubes of iron, from which the sand, &c., within them is removed by means of an air-pump, and the pipes are then sunk.

In recent railway bridges, cylinders have been much used to form both piles and piers. They are of cast iron, and made in pieces (of about six feet in height), which are applied one on the top of another. The sand or gravel is removed from the inside of the first laid, which thus sinks down; another cylinder is placed above it, and the same process continued till it also has sunk sufficiently; and so on, cylinder over cylinder, till a solid foundation is reached. The requisite number of cylinders is then piled up to form the pier above ground.

PILES, or **HÆMORRHOIDS**, are small tumors, situated either within or on the verge of the anus. They consist of folds of mucous and sub-mucous membrane in an inflamed, infiltrated, or permanently thickened condition, and usually contain enlarged veins. There are several varieties of these tumors. Sometimes the pile is mainly composed of a little knot of varicose veins in the sub-mucous tissue; in this case it is readily emptied, by pressure, of the fluid blood contained in it, which, however returns when the pressure is removed. Sometimes the blood in a dilated vein coagulates, forming a solid tumor surrounded by tissues, thickened in consequence of inflammation; or the tumor may consist of a kind of erectile tissue formed by an abnormal condition of the vessels of the mucous membrane; this variety is especially liable to bleed. These tumors are divided into *bleeding* and *blind* piles, according as they are or are not accompanied with hæmorrhage; and into *internal* and *external* piles, according as they are within or without the sphincter muscle of the anus.

The following are the general symptoms of this affection. The patient, after having experienced for a varying time a feeling of heat, fulness, and dull pain about the lower part of the bowel, becomes conscious of a sensation as if there were a foreign body in the anus; and on examination after an evacuation, discovers a small tumor, usually about the size of a grape, which either remains outside, or is retracted, according as it originated without or within the sphincter. This tumor gradually increases, and others form around it, until a mass at length results as large as a pigeon's egg, or larger. In its ordinary *indolent* state the tumor has little sensibility, and occasions comparatively little annoyance; but when it is *inflamed* (from strangulation of the sphincter muscle, or from any other cause), it is exquisitely tender to the touch, and is the seat of burning and stinging sensations, rendering the evacuation of the bowels (and sometimes of the bladder also) difficult and painful. In women, an inflamed pile may cause pain in the back, irritation of the womb, with mucous discharge, and many other anomalous symptoms. In severe cases, the patient can neither stand nor sit with comfort, and only finds relief in a horizontal position.

Piles may be caused by any circumstances which cause congestion in the lower bowel, such as luxurious and sedentary habits of life, pregnancy, and such diseases of the liver as tend to check the return of blood from the veins of the rectum. Moreover, anything that causes irritation of the rectum, such as acrid purgatives and especially aloes, dysentery, inflammation of the prostate gland, &c., may cause piles. But of all causes, constipation is probably the most frequent; it operates in producing them partly by the pressure of the accumulated and hardened feces upon the veins carrying the blood away from the rectum, and partly by the straining and irritation such feces occasion during their evacuation.

In the treatment of piles, it is expedient to relieve the congested state of the lower bowel by one or two doses of sulphate of magnesia, and a cooling vegetable diet, after which the continued use of mild laxatives should be resorted to. A teaspoonful of an electuary, consisting of an ounce of confection of senna, half an ounce of cream of tartar, and half an ounce of sulphur, if taken in the middle of the day, usually acts gently about bedtime, which is far the best time for the bowels of patients of this kind to act, as the parts irritated by the passage of the evacuation become quieted during the night. In long-standing cases, in which there is general relaxation of the mucous membrane, the confection of pepper in doses of a drachm may be given thrice daily with advantage, or a scruple of common pitch may be taken at bedtime in the form of pills or in capsules. Amongst the milder forms of local treatment must be mentioned (1) the injection of the rectum with cold water both before and after the motion; (2) washing the anus with yellow soap and water after each evacuation; (3) the application of gall ointment or of other astringents; and (4) the injection of astringent lotions, as, for instance, of sulphate of iron, in the proportion of a grain to an ounce of water. If these fail, recourse may be had to pressure by means of instruments specially devised for the purpose; to the application of strong nitric acid, which, in the case of internal piles, affords the most speedy and effective means of relief (the operation must, of course, be performed by a surgeon, and if the parts cannot be protruded, the acid must be applied through the speculum); to ligature; or, in the case of external piles, to excision. When the piles are inflamed, leeches to the anus (but not applied directly to the tumors) are sometimes required; but the inflammation generally subsides under the influence of rest in the horizontal position, fomentations, poultices, and low diet.

The treatment of the hæmorrhage that frequently accompanies piles requires a few words. If the bleeding is moderate in quantity, and has continued for some time without inducing weakness or any other bad symptom, it is not expedient to interfere with it. When, however, it obviously requires checking, the effect of cold water injected into the rectum, as already recommended, should be tried, and, in case of its failing, astringent injections

should be had recourse to. At the same time, the patient should remain in the horizontal position, and take the medicines usually prescribed for internal hæmorrhage, amongst which may be especially mentioned oil of turpentine, in doses of twenty drops three or four times a day, or ergot of rye in divided doses to the extent of a drachm daily. In rare cases, it is necessary to tie a vessel, or to touch it with a red-hot wire (through the speculum), or to plug the anus.

PI'LEUS. See **FUNGI**.

PILEWORT. See **RANUNCULUS**.

PI'LGRIM (Ital. *pellegrino*, Lat. *peregrinus*, 'a visitor of foreign lands'). A pilgrim is one who visits, with religious intent, some place reputed to possess especial holiness. The early Christians, like the Jews and the pagan Gentiles, regarded certain places with special religious interest; above all, the Holy Land, and particularly the scenes of the Passion of our Lord at Jerusalem. St. Jerome (Ep. xlv.) refers the practice of visiting Jerusalem to the discovery of the Holy Cross by St. Helena. He himself was a zealous pilgrim; and throughout the 4th, 5th, and 6th centuries, pilgrims habitually undertook the long and perilous journey to the Holy Land from almost every part of the West. Other sacred places, too, were held to be fit objects of the same visits of religious veneration. The tombs of the apostles Peter and Paul, and of the martyrs in the catacombs at Rome, are so described by St. Jerome (*Commentar. in Ezechiel*). St. Basil speaks in the same terms of the tomb of the Forty Martyrs; and the historian Theodoret tells of not only visiting such sanctuaries, but of hanging up therein, as offerings, gold and silver ornaments, and even models of hands, feet, eyes, &c., in commemoration of the cures of diseases supernaturally obtained as the fruit of these pious visits.

The **PILGRIMAGE**, however, pre-eminently so called, was that of the Holy Land; and even after Jerusalem had been occupied by the Saracens, the liberty of pilgrimage, on payment of a tax, was formally secured by treaty; and it was from the necessity of protecting pilgrims from outrage, that the well-known **MILITARY ORDERS** (q. v.) had their origin. The **CRUSADES** (q. v.) may be regarded as a pilgrimage on a great scale; the direct object being to secure for the Latin Christians immunity of pilgrimage. On the other hand, the final abandonment of the Crusades led to a great extension of what may be called domestic pilgrimage, and drew into religious notice and veneration many shrines in Europe, which, after the lapse of time, became celebrated places of pious resort. The chief places of pilgrimage in the West were: in Italy—Rome, Loretto (q. v.), Genetsano, Assisi; in Spain—Compostella, Guadalupe, Montserrat; in France—Fourviers, Puy, St. Denis; in Germany—Oetting, Zell, Cologne, Trier, Einsiedeln; in England—Walsingham, Canterbury, and many others of minor note. The pilgrim commonly bound himself only by a temporary vow (differing in this from the palmer), which terminated with the actual visit to the place of pilgrimage, or at least with the return home, and by which he was bound for the time to elasticity and to certain other ascetic observances. The costume consisted of a black or gray gabardine, girt with a cincture, from which a shell and scrip were suspended, a broad hat, ornamented with scallop-shells, and a long staff. Many abuses arose out of these pilgrimages, the popular notions regarding which may be gathered—although, probably, with a dash of caricature—from Chaucer's *Canterbury Tales*. Pilgrimages, which have always subsisted in Italy, Spain, Southern Germany, and Switzerland, had gone much into disuse in France during and since the Revolution. In late years, however, pilgrims have resorted in large numbers, not only to the ancient sanctuaries of Notre Dame de la Garde, de Fourviers, de Puy, &c., but also to La Salette, Lourdes, Paray-le-Monial, and Pontigny. In 1873 and 1874, organized parties of pilgrims on a very large scale from France, Belgium, England, the United States, &c., visited the sanctuary of Paray-le-Monial, the place at which the vision of Marie Alacoque, which gave rise to the devotion to the Sacred Heart of Jesus (q. v.), is recorded to have taken place. In 1874, 500 English pilgrims visited Pontigny. Numerous pilgrimages have also been held in Belgium.

PILLAR, a detached support like a column; but its section may be of any shape, whereas the column is always round. Pillars have been used in all styles of architecture, and their forms and ornaments are usually amongst the most characteristic features of the style. The Greek and Roman pillars (or columns) are the distinguishing elements in the various orders. In Gothic architecture, also, the pillars are of different forms at the various epochs of that style. First, in the Norman period, we have plain massive pillars, square, circular, and octagonal, frequently ornamented with zigzag ornaments, spiral bands, &c., on the surface (fig. 1). As vaulting progressed, the system of breaking the plain surface, and giving to each portion of the vaulting a separate little column or shaft to support it, was introduced. This was

done either by attaching shafts to the circular pillars, or by cutting nooks in the pillar and setting little shafts in them, thus: *a, b, fig. 2.*

In the Early Pointed Style a plain circular or octagonal pillar, with a number of small shafts attached around it, is a favorite arrangement, thus: *c, d, fig. 2.*

In this style, the attached shafts are very frequently banded to the main pillar at different heights, and they are some times made of a finer material, such as Purbec marble. In the Dec-

Fig. 1.—Norman Clustered Pillar.

Fig. 2.

olated Style the pillar is of a lozenge form, and not so much ornamented with detached shafts as with mouldings; plain, circular, or octagonal pillars, however, are used in this, as in all the styles. The mouldings and shafts are usually filleted; and some of the mouldings run up into the arch without any cap. In Perpendicular the same idea is further carried out; the mouldings become thinner, and are more frequently run up into the arch without caps. See FLAMBOYANT.

PILLAR SAINTS—called also '**STYLITES**' (Gr. from *stylos*, a column), '**Pillarists**,' '**Holy Birds**,' '**Air Martyrs**,' and several similar names—a very remarkable class of anchoritical Ascetics (see ASCETICISM), chiefly of Syria, who, with a view to separating themselves more completely from earth and fellow-men, took up their abode on the tops of pillars, on which they remained without ever descending to earth, and exposed to all the variations of a Syrian climate. The earliest of them, and the most celebrated, Simeon (called also Simon) the Stylite, had been a monk, and had lived, in the beginning of the 5th c., in extreme seclusion in his monastery for nine years, without ever moving from his narrow cell. Increasing in enthusiasm, he withdrew to a place about 40 miles from Antioch, where he built a pillar, on the top of which, only a yard in diameter, he took up his position. From this pillar he removed to several others in succession, each higher than its predecessor, till at last he attained to 40 cubits, or about 60 feet, in height. In this mode of life he spent 37 years, his neck loaded with an iron chain, and his lips engaged in constant prayers, during the recitation of which he bent his body so that his forehead touched his feet. His powers of fasting were no less marvelous; he is said to have frequently limited himself to a single meal in the week, and during the forty days of Lent abstained entirely from food. The fame of his sanctity brought crowds of pilgrims from the most distant countries, even Britain itself, to see him; and the admiration of his austerities is said to have converted many pagans and Saracens to the church. In trial of his virtue, through the test of humility, some neighboring monks reproaching him with vanity, and the love of novelty in this extraordinary mode of life, ordered him to come down from his pillar. Simeon prepared without hesitation to comply, and the compliance was accepted as an evidence of his perfect humility and holiness of purpose. It is said that in consequence of an ulcer which was formed on one of his legs, he was obliged for the last year of his life to remain on his pillar upon one foot. In this position he died in 460, aged 72 years.

A disciple of Simeon, named Daniel, succeeded to his reputation for sanctity; and to his mode of life, which he maintained for 33 years, in the still more trying climate of the shores of the Bosphorus, about 4 miles from Constantinople. The marvels of Daniel's career are still more startling. He was sometimes almost blown by the storms of Thrace from the top of his pillar. At times for days together he was covered with snow and ice. How he sustained life, what nourishment he took, was a mystery even

to his disciples. The emperor at length insisted on a covering being placed over the top of the pillar, and Daniel survived till the year 494. In Syria there were many pillar saints as far down as the 12th c.; but in the west, Daniel is all but a solitary example. A monk named Wulfalich, near Trier, attempted the pillar-life in the 6th c., but the neighboring bishops compelled him to desist, and destroyed his pillar.

PILLIBHIT, or **PHILLIBIT**, a town of India, in the North-west Provinces, 28 miles N.E. by E. from Bareilly. P. is a place of considerable trade. Pop. 30,000.

PILLNITZ, a palace and ordinary summer residence of the royal family of Saxony, in a beautiful situation seven miles south-east of Dresden. The grounds are finely diversified, and the walks ascend to the summits of hills, of which one is nearly 1000 feet high. P. acquires a historic interest from the meeting of princes held in the castle in August 1791, when the Declaration of Pillnitz was framed, according to which Austria and Prussia agreed to declare the circumstances of the king of France (then a prisoner in the Tuileries, after his ineffective flight to Varennes) to be a matter of common interest to the sovereigns of Europe, and to express the hope that common cause would be made for his restoration. The emperor and the king of Prussia were resolved to use force in order to effect this result; but any immediate interference on their part was rendered unnecessary by Louis's acceptance of the constitution as modified by the National Assembly, after which he was again placed on the throne.

PILLORY, an engine for the public punishment of criminals, disused in Britain since 1837; but previous to that time commonly employed, as it also was in France and Germany. It consisted of a stout plank fixed like a sign-board on the top of a pole, the pole being supported on a wooden platform elevated above the ground. Above, and parallel to this plank another of similar dimensions was placed in a similar position with respect to the pole, and fixed to the former by a hinge, being thus capable of being moved upwards from it, or closed upon it, when necessary. A large circular hole is cut, with its center in the line of junction of the two planks, and two corresponding holes of smaller size are formed, one on each side of it; the large hole is for receiving the neck, and the two smaller the wrists. When a criminal is to be placed in the pillory, he is made to mount and stand upon the platform; the upper of the two hinged planks is raised to allow the culprit's neck and wrists to be inserted in their proper grooves, and then brought down into its place, and fastened by a padlock, or in some other way. See for illustration the wood-cut to the article OATES, TITUS. The pillory seems to have existed in England before the Conquest, in the form of the stretch-neck (an instrument by which the neck only was confined), and was originally intended according to the '*Statute of the Pillory*' (51 Hen. III. c. 6), for 'forestallers, users of deceitful weights, perjury, forgery, &c.,' and all such dishonorable offences. Its use was exclusively confined to this class of offenders till 1637, when restrictions were put upon the press, and all who printed books without a license were put in the pillory. From this time it became the favorite mode of punishing libelers (or those who were considered to be such by the government), authors and publishers of seditious pamphlets, or of strictures on the government; and many eminent men were accordingly from this time put 'in and on the pillory,' among whom may be mentioned Leighton, Lillburn, and Warton the printers, Prynne, Dr. Bastwick, Daniel Defoe, &c.

The insufficiency of the pillory as a means of inflicting a definite amount of punishment was now apparent, for to those who were popular favorites it was no punishment at all, while those who were objects of popular dislike were ill-used to such an extent as occasionally to cause death. The sufferers above mentioned being popular favorites, or having at least a numerous class of supporters, were shaded from the sun, fed, and otherwise carefully attended to; while the encouragement, applause, and sympathy of the crowd around converted the intended punishment into a triumph; but such men as Titus Oates, and the class of offenders including perjurers, swindlers, polygamists, &c., who were objects of popular hatred and disgust, were pelted with rotten eggs (the favorite missile), garbage, mud, sometimes even with more dangerous missiles. In 1814 the celebrated naval hero Lord Cochrane (see DUNDONALD, EARL OF) was sentenced to the pillory, but the government of the day was not prepared to brave the consequences of such an act, and the sentence was not carried into effect. In France the pillory was anciently called *pilori*, and in recent times *carcan*, from the iron collar by which the criminal's neck was attached to the post; but punishment by this mode was abolished in that country in 1832.

PILLS are the most generally convenient and popular of all forms of medicine. They are formed from masses of a consistence sufficient to preserve the globular shape, and yet not so hard as to be of too difficult solution in the stomach and intestines. This form is especially suitable for (1) all remedies which operate

in small doses, as metallic salts; (2) those which are designed to act slowly and gradually, as certain alteratives; (8) those which are too readily soluble when exhibited in other forms; (4) substances whose operation it is desirable to retard until they have reached the lower intestines, as in certain pills for habitual costiveness; (5) bodies whose specific gravities are too inconsiderable to allow their suspension in aqueous vehicles; and (6) fetid substances: while it is unsuitable for (1) medicines which require to be given in large doses; (2) deliquescent salts; (3) fluid or semi-fluid substances, such as oils, balsams, &c., which require a very large proportion of some dry powder to render them sufficiently tenacious to form into a mass; (4) substances so insoluble, that when exhibited in solid form they pass through the intestinal canal unaltered, as extract of logwood (Paris's *Pharmacologia*, 9th ed. p. 550).

Many substances, such as vegetable extracts, may be at once formed into pills without any addition; but most substances require the addition of a material termed an excipient, for converting it into a pill-mass. The excipients in most common use are bread-crumbs, hard soap, extract of liquorice, mucilage, syrup, treacle, honey, castor oil, and conserve of roses. From the property of preserving pills for a long time in a properly soft state, the most valuable excipient is the conserve of red roses; and, perhaps, next to it treacle is the most valuable excipient, as it does not undergo any change by time, but maintains a proper consistence, and preserves the properties of vegetable powders unimpaired for years. It is common to place pills in some fine powder, to prevent them from adhering to each other, and to conceal their taste. For this purpose liquorice powder, wheat flour, starch, and magnesia are generally used in this country, and lycodium on the continent. Pills retain their moisture and activity far longer in small bottles than in the ordinary pasteboard boxes. The ordinary weight of a pill is five grains; if it much exceeds that weight, it is too bulky to swallow conveniently if it consist of vegetable matter. It is very common to meet with patients who express their inability to take this form of medicine. If, however, they practise with a small globular mass, towards which they feel no repugnance, as a pellet of bread or a currant, placing it on the back of the tongue, and gulping it down with water, they will soon get over the difficulty.

PILOT, is a person specially deputed to take charge of a ship while passing through a particular sea, reach, or dangerous channel. The intricacy of almost all coast navigation renders it impossible that any navigator, however skilful, can be master of all the waters to which he may have to sail his ship; and the risk of failure, through ignorance of local dangers, is therefore avoided by transferring the direction of her course to some one perfectly acquainted with the spot. The man to whom so much is intrusted must be a responsible person, and therefore in all countries qualified sailors are officially licensed to act as pilots in their districts, and they are granted the monopoly. The origin of the word pilot is uncertain, but is probably taken from or nearly identical with the Dutch *pijloot*, which is compounded of *pielen*, to sound the depth, and the root which appears in *D. lootsman*, *O. E. lodesman*, and signifies to lead, direct. Pilot thus means one who conducts a vessel by sounding. The laws of Wisby, promulgated at least as early as the 14th c., and subsequently incorporated in nearly every maritime code, render it compulsory on the master of a ship to employ a pilot when sailing near a coast.

The British laws relating to pilots were revised and consolidated by the act 16 and 17 Vict. c. 129. Certain fees are established in proportion to the distance and responsibility; and the master of every vessel, above 50 tons, passing up the Channel or the Thames, or *vice versa*, is required to accept the services of the first pilot tendering, provided he shows his license as a proof of qualification. Except in matters of discipline, the command of the vessel is then vested entirely in the pilot, who can have the sails, steering, &c., of the ship carried on entirely at his discretion until the limit of the pilot's district is passed, except that the captain resumes his powers when the question of taking up ground in a harbor is concerned. The fees vary with the draught of the ship and the distance; as specimens, may be cited the highest and lowest in the London district: a ship drawing 22 feet of water is piloted from Orfordness to Blackwall for £27, 12s.; a ship drawing not more than 7 feet is guided from Gravesend Reach to Long Reach for 9s. 3d.

Pilots are associated in guilds called Brotherhoods, of which the principal are the Brotherhood of the Trinity House of Deptford-Stroud, situated on Tower-Hill, which has jurisdiction over the Thames, Medway, and the coast from Harwich to the Isle of Wight; and the Trinity Houses of Kingston-upon-Hull and Newcastle-on-Tyne. There are also societies of pilots at the larger ports out of these districts, the government in such case being vested in certain officials lawfully appointed as 'pilotage authorities.' Their powers over the members, &c., are defined in the act above quoted, and in the Merchant Shipping Act of 1854, 17 and 18 Vict. c. 104, sections 380—388.

Pilots board vessels entering their districts in boats conspicuously painted, on the bows and sails of which must be the man's distinguishing number as shown by his license. The boat also bears a flag of comparatively large size, of red and white divided horizontally. A ship requiring a pilot hoists a square blue flag. In passing up or down the Thames, every ship above 50 tons or 6 feet draught must bear a pilot; but her master or first-mate may act by license in that capacity, if he have passed the necessary examination. A master is subject to a penalty for sailing without a pilot; and, on the other hand, so also is any person, without a license, or whose license has been forfeited, presuming to act or offering to act as a pilot.

In the navies of some countries the pilot is a permanent officer of the ship, and has charge of her course; but his functions in that case approach nearer to those of the British navigating officer. Large French vessels have often several sailing pilots called *pilotes hauturiers*, and a *pilote côtier* or *lamanier*. The ancient laws of France contained provisions for the education and regulation of both these classes.

The general rule as to the responsibility of the owners of the ship is, that no owner or master of a ship is answerable to any person whatever for any loss or damage, occasioned by the fault or incapacity of any qualified pilot acting in charge of such ship within any district where the employment of the pilot is compulsory.

PILOT-FISH (*Naucrates ductor*), a fish of the family *Scomberidae*, and belonging to a section of that family in which the first dorsal fin is represented by mere spines, and there are no finlets behind the second dorsal and anal fins as in the mackerel, &c. The shape of the P. is very similar to that of the mackerel. It is usually about a foot long; the general color silvery grayish-blue, five dark-blue transverse bands passing round the whole body. Its flesh is very delicate, and resembles mackerel in flavor. It is common in the Mediterranean, and appears to be widely-diffused through the warmer parts of the ocean, often following ships for a long time and very far, in which way it has been known to come from Alexandria to Plymouth. It is, however, of rare occurrence even on the southern coasts of Britain. It is supposed to be the *Pompilus* of the ancients, which was believed to point out their desired course to sailors. It is often seen in the company of a shark, and is therefore very commonly supposed to direct the shark to its prey. Concerning this many wonderful stories are to be found in the writings both of voyagers and of naturalists. It has been contended, on the other hand, that the P. merely follows the ship along with the shark for the same object that gulls follow the steam-boats on our coasts, to feed on anything eatable that may fall or be thrown overboard; or that it attends the shark in order to seize small morsels of its large prey. The following statements of Dr. Bennett may be received with confidence: 'I have observed that if several sharks swim together, the pilot-fishes are generally absent; whereas, on a solitary shark being seen, it is equally rare to find it unaccompanied by one or more of these reputed guides. . . . The only method by which I could procure this fish was, that when capturing a shark I was aware these faithful little fishes would not forsake him until he was on board; therefore by keeping the shark, when hooked, in the water until he was exhausted, or, as the sailors term it, "drowned," the pilot-fish kept close to the surface of the water over the shark, and by the aid of a dipping-net fixed to the end of a long stick I was enabled to secure it with great facility' (*Gatherings of a Naturalist*).—A much larger species of *Naucrates* is found on the coasts of South America.

PILPAI. See BIDPAI.

PILSEN, a town of Bohemia, in a fertile and beautiful valley at the confluence of the Mies and the Beraun, 52 miles west-south-west of Prague. The church of St. Bartholomew (built in 1292), the town-hall, and the house of the Teutonic Knights are interesting Gothic edifices. The town also contains a gymnasium and other educational institutions, an arsenal, theater, and a number of churches and convents. P. has leather and cloth-factories, a great alum-work, iron and coal mines, and an important brewery. Pop. (1880) 38,883.

PIMENTO, **PIMENTA**, **ALLSPICE**, or **JAMAICA PEPPER**, a well-known spice, is the dried fruit of *Eugenia Pimento* (see *EUGENIA*), a small West Indian tree, which grows to the height of twenty to thirty feet, and has oblong or oval leaves about four inches long, of a deep shining green, and numerous axillary and terminal trichotomous panicles of white flowers, followed by small dark-purple berries. The P. tree is much cultivated in some of the West Indian Islands. It is a very beautiful tree, with straight trunk and much branching head; and about the month of July is covered with an exuberance of flowers, which diffuse a rich aromatic odor. The leaves and bark partake of the aromatic property for which the fruit is valued. The fruit, when ripe, is filled with a sweet pulp, and the aromatic property, which so strongly characterizes it in an unripe state,

has in a great measure disappeared. The gathering of the berries, therefore, takes place as soon as they have reached their full size, which is about that of pepper-corns. They are gathered by the hand, and dried in the sun on raised wooden floors, during which process great care is taken, by turning and winnowing, to prevent them from being injured by moisture. Their color changes in drying, from green to reddish-brown. When dry they are packed in bags for the market. Some planters kiln-dry them.—The name *Allspice* was given to *P.* from a supposed resemblance in flavor to a mixture of cinnamon, nutmeg, and cloves.

Pimento.

P. is much employed in cookery, and is also used in medicine as a carminative and stimulant, to prevent the griping of purgatives, and to disguise the taste of nauseous drugs. It depends for its properties chiefly on a volatile oil, *Oil of P.*, which is obtained from it by distillation with water, and is sometimes used to relieve toothache, and for making the *Spirit of P.* (or of *Allspice*) and *P.* (or *Allspice*) *Water* of the shops.

PIMPERNEL (*Anagallis*), a genus of plants of the natural order *Primulaceae*, having a wheel-shaped corolla, and the capsule opening by division round the middle. The species are elegant little annual and perennial plants, natives chiefly of temperate climates. The flowers are not large, but very beautiful.—The SCARLET *P.* (*A. arvensis*) is a common plant in Britain, occurring as a weed in fields and gardens; it is common also in most parts of Europe, and in many parts of Asia. The flowers are of a fine scarlet color, with a purple circle at the eye. There is a common belief in England, mentioned by Lord Bacon, that when this plant opens its flowers in the morning a fine day may be expected; and they certainly close very readily on the approach of rain. They usually open about eight in the morning, and close about noon.—The BLUE *P.* (*A. carulea*), is far less common in Britain, but very abundant in some parts of Europe.—The BOG *P.* (*A. tenella*), frequent in bogs in England, but rare in Scotland, is an exquisitely beautiful plant.—Several species are cultivated in our flower-gardens.—Acrid properties prevail in this genus, and *A. arvensis* has been used medicinally in epilepsy, dropsy, and mania.—The name WATER *P.* is given to *Samolus Valerandi*, also called *Brookweed*, another British plant of the same order, with racemes of small white flowers, growing in watery gravelly places. It is supposed to be the *Samolus* which Pliny says the Druids gathered fasting, with the left hand, and without looking at it, ascribing to it magical virtues in the cure and prevention of diseases in cattle. Its geographic distribution extends over almost all the world.

PIN. As a requisite of the toilet, &c., pins were first used in Britain in the latter part of the 15th c.; they were at first made of iron wire, but in 1540 brass ones were imported from France by Catherine Howard, queen of Henry VIII. Several inventions, however, were previously in use for holding together parts of the dress, such as buckles, brooches, laces, clasps, hooks, &c. At first pins were made by filing a point to a proper length of wire, and then twisting a piece of fine wire around the other extremity, or fixing it after twisting, in order to form a knob or head; and ultimately these operations were so skillfully conducted, that a completely round head was made of very small size, and scarcely showing the nature of its construction. Some pins are still made in this way. It is suprising how many operations are needed to complete so small an article. They are as follows: 1. *Straighten-*

ing and Outting the Wire.—The straightening is necessary, because the wire-drawers coll the wire as they make it upon a cylinder, and when it is unrolled, the coils remain. It is therefore drawn through an arrangement of upright iron rods which completely straighten it, after which it is cut into lengths of 30 feet, and these are again reduced to lengths of four pins. 2. *Pointing.*—This is done by two operations and different workmen, each standing at a separate grindstone; the first is the rough grinder, and the second the finisher. Each holds with the thumb on the palm of the hand a number of the wires amounting to 30 or 40, and by a movement of his thumb he manages to make the wires turn round so as to make a point to each as he holds them to the grind-stones, the second of which, being of a fine material, gives them a smooth finish; they are then reversed, and the other end pointed. 3. *Cutting.*—The length of a single pin is cut off of each end of these pieces; the intermediate portions are then handed back to the pointers, and each end receives a point, after which they are divided into two, and thus the four pin piece is reduced into single pin lengths, each having a point.

4. *Twisting the Heads.*—These are made of very thin wire, which is coiled twice, by means of a lathe, around the end of another piece of wire the same thickness as the pins. 5. *Cutting the Heads.*—The head being formed on the thin wire, it is handed to another workman who cuts it off; these two operations are performed with great rapidity, so great, indeed, that as many as 12,000 have been made in an hour. 6. *Annealing the Heads.*—This is softening them by putting some thousands into an iron ladle, and after making them red hot, plunging them into cold water. 7. *Stamping or Shaping the Heads.*—This is pressing the heads into a better shape by means of a small lever press, and at the same time fixing them on the pins; a good worker will do as many as 12,000 to 15,000 per day. 8. *Yellowing or Cleaning the Pins.*—This is done by a process which is often called *souring*; it consists in boiling them for about half an hour in the dregs of sour beer, or a solution of argol or cream of tartar, and then washing them in clean water. 9. *Whitening or Tinning.*—In this process a large copper pan is used, and in it is first placed a layer of about six pounds of the cleaned or yellowed pins, and over these a layer of grain-tin to the amount of about eight pounds. Several alternate layers of pins and tin are put in one vessel, and then by a pipe arranged inside the copper pan water is gently poured in, and goes through the pipe to the bottom, first rising up through the different layers so gently as not to disturb them. Fire is now applied to the bottom of the pan, and when it is nearly boiling its surface is sprinkled with a quarter of a pound of cream of tartar and the whole is slowly boiled for half an hour, then poured into a strainer and shaken, to separate the pins from the grain-tin and liquid; by this process a thin deposit of tin has been thrown on the pins, which now are white instead of yellow; without the souring this would not take place, it being essential that they should be quite free from any oxidation or soil. 10. *Washing.*—The pins are now thoroughly washed in pure water. 11. *Drying and Polishing.*—They are now put into a large leathern bag with a quantity of bran, and violently shaken backwards and forwards by two men. 12. *Winnowing.*—The bran is next separated by fanning. 13. *Pricking the Papers to receive the Pins.*—This is now done by an ingenious machine, through which the papers are passed, and which, at regular intervals, arranged according to the size of the pins, pinches up a fold of the paper, and at the same time pricks the holes to receive the pins, and then places the pins in their places. Formerly this required a separate operation. Thus fourteen persons were required to make and put up for sale a pin, and in some manufactories this is still the case; but in all the large establishments machines are now employed, and an immense reduction of hand labor is effected by them.

The first machine was invented by Lemuel Wellman Wright, of the United States, in 1824. This did very little more than make

solid heads to the pins, by a process in principle like that used for nail-making—viz., by driving a portion of the pin itself into a counter-sunk hole. The action, however, was automatic, and consisted in an arrangement by which the wire was seized in two small grooved cheeks, as in figs. 1 and 2, which represent them

separated. Fig. 1 has the groove empty, but in fig. 2 is seen the wire which projects at *a*. When both cheeks are placed face to face, and the wire is held tightly in the groove with the small portion (*a*) projecting, a small ram or hammer connected with the machine strikes on *a*, and compresses it into the small cup-shaped depression *b*, and thus the head is formed, as in fig. 3. The pointing and dressing of the pins was afterwards carried on as described in the processes for hand-made pins. Since Wright's invention many remarkable improvements have been effected in these machines, which have consequently become very complicated in their details, although the principles upon which they act are very simple.

No description would convey a satisfactory idea of these wonderful pieces of mechanism, which now, without the aid of hands, complete the pin in all respects except the coloring and polishing; but a slight account of the leading features will enable the reader to understand their mode of working. First, then, a reel of wire as it comes from the wire-drawer is placed in the rear of the machine, and the end of the wire is taken hold of by a pair of nippers, which pull it over a fixed *straightening board*, and pass it on completely straightened, until it is seized by two cheeks similar to those in figs. 1 and 2, when a cutter descends and cuts it off, leaving the projecting part for the head; on the withdrawal of the cutter, the hammer flies forward, and makes the head as before described; the cheeks open, and the pins drop on to a sloping metal plate finely grooved, down which they slip with the heads upwards, until the end which is to be pointed comes in contact

Fig. 4.

with a cylindrical roller with a grinding surface, which soon grinds points upon them, owing to two or three ingenious arrangements: the first is, that the grooved surface of the plate by which the pins descend terminates a little above the grinding roller, then a slight depression is given to the sloping plate and also to the roller, so that one end is an inch or two lower than the other; therefore, as the pin descends the groove (*a*, fig. 4), and is thus

Fig. 5.

brought down the inclined plate until it lies on the smooth part (*b*, fig. 4), where it is highest, and with its end in contact with the grinding roller (*c*) which is revolving, the pin itself is compelled by the friction of the roller to turn round, and gradually descends from the upper to the lower part of the inclined plate (*d*), and then falls into a box placed to receive it. This is attempted to be shown in fig. 4. These operations are performed so rapidly, that

they can scarcely be followed by the eye, and the pins fall into the box beautifully pointed in a complete stream. They are then *yellowed, tinned*, and prepared for papering, which is a remarkable process.

The machine by which it is done is worked by two children; one feeds the machine with pins, the other with papers. The first part of the machine is a box, about 12 inches long by 6 inches broad and 4 inches deep; the bottom is made of small square steel bars, sufficiently wide apart to let the shank of the pin fall through but not the head, and they are just as thick as the space between papered pins; the bottom of the box, with the row of pins hanging through it, are seen in fig. 5. The lower part of the bottom of the box at *a* is made to detach itself as soon as the row of pins is complete, and row after row at regular intervals is received and passed down a corresponding set of grooves, until they reach the paper which, as before described, is pinched into regular folds and pierced to receive the pins, which, by the nicest imaginable adjustments, come exactly to their places, and are pressed into them. In this way many thousands of those neat-looking paper packages of pins, with which all are familiar, are put up in one day by two little girls, aided by these wonderful machines.

PI'NA CLOTH, a very beautiful fabric made of the fibres of the leaves of the pine-apple plant (*Ananassa sativa*), and other allied species. This cloth is only made in Manilla, and in its manufacture resembles horse-hair cloth, because the threads both of warp and weft are each single unspun fibres, consequently only small pieces can be made; the workers have, however, a plan of joining the fibres of the coarser kinds end to end, so as to make warp threads of considerable length. Pina cloth is very strong, and the better sorts far excel the finest lawns in texture. It is chiefly employed in the manufacture of ladies' pocket-handkerchiefs, which often have their costliness much increased by beautiful embroidery.

PI'NCHBECK is an alloy of zinc and copper, in which the proportions slightly differ from those which constitute brass; 3 parts zinc to 16 of copper constitute this material, instead of one part of the former to two of the latter as in common brass. Pinchbeck, when new, has a color resembling red gold, and it was at the beginning of the present century much employed in making watch-cases and other small articles in imitation of gold.

PIND DADU'N KHAN, a town in the Punjab, stands on a narrow verdant plain on the right bank of the Jhelum, and at the southern base of the Salt Range or Kalabagh Mountains, 110 miles north-west of Lahore. The town consists of three groups of houses, four miles from the Jhelum. The houses are built of mud, but the framework is of cedar-wood. In the vicinity, salt is extensively raised in the Salt Range. See **PUNJAB**. Entire population (1872), 13,340.

PI'NDAR (Gr. *Pindaros*), the great lyric poet of Greece, was born about 522 B.C., of a noble family of Thebes, at Cynoscephalæ, a village in that territory. His genius for music was hereditary, and at an early age he was sent by his father, himself a flute-player, to receive instruction in the same art from Scopelinos. At this time his genius for poetry too—foreshadowed, according to later writers, by a swarm of bees miraculously resting on his lips when asleep—began to develop itself, and so he went to Athens to be placed under the tuition of Lasus of Hermione, the founder of the Athenian school of dithyrambic poetry. Before completing his 20th year he returned to Thebes, where he continued to pursue his studies under Myrtis and Corinna, of Tanagra, two poetesses then famous in Bæotia. With both of these instructresses he contested the prize for music at Thebes, but was five times defeated by Corinna. He was still a young man when he entered on his professional career as a poet, and his services soon came to be in great request on festive occasions throughout all the Hellenic states. He composed choral songs for Hiero, tyrant of Syracuse; Alexander, son of Amyntas, king of Macedonia; Theron, tyrant of Agrigentum; Arcesilaus, king of Cyrene; and also for many free states and private individuals.

He won not only the admiration of his employers for his lyrical genius, but also their respect for his independent character, which, amid all the presents and rewards conferred upon him, never degenerated into that of the poet who merely performed for hire. He was especially the favorite of Alexander, king of Macedonia, and of Hiero, tyrant of Syracuse; and it is said that to the praises he lavished on the former of these monarchs his house owed its preservation at the hands of Alexander the Great, when he reduced the rest of Thebes to ruins. His life was for the most part spent abroad at the courts of kings, and at the scenes of the great public games; and at one period, 478 B.C., he resided at Syracuse at the court of Hiero for the space of four years. He died most probably in 442 B.C., in his 80th year. Of the immense number of his poems, consisting of hymns to the gods, pæans, dithyrambs, odes for processions (*prosodia*), maidens' songs (*partheneia*), mimic dancing songs (*hyporchemata*), con-

vivial songs (*scolia*), dirges (*threnoi*), and encomia on princes, we only possess fragments. His *Epinikia*, or Triumphal Odes, however, have come down to us entire; and it is from these—divided into four books, and celebrating the victories won in the Olympian, Pythian, Nemean, and Isthmian games respectively—that we must form an opinion of P. as a poet. A victory at these games conferred honor not upon the winner and his family only, but also on the city to which he belonged; and for its celebration—which began with a procession to the temple, where sacrifice was offered, and ended with a convivial banquet—a poem was specially composed, and was sung by a chorus either during the procession, or, more frequently, at the banquet (*comus*).

P.'s poetical style is peculiar. Full of bold conceptions and striking metaphors, his manner is so rapid and so subject to abrupt transitions, as to render him not only a difficult but an obscure composer. Typical examples of his strength, as well as of his weakness, will be found in the Second Olympian and First Pythian Odes, where the description of the Islands of the Blest in the former, and of an eruption of Mount Ætna in the latter, are brilliant offsets to the shadowy mythological allusion and the undeveloped metaphor which also characterize them. His metres, in spite of the able efforts of Böckh, still remain to be satisfactorily elucidated; and all that we can here say of them is, that he makes chief use of the Dorian rhythm, and not unfrequently of the Æolian and Lydian. He has been fortunate neither in his numerous imitators nor translators—Gray being, perhaps, the most successful among the former, and Carey, Abraham Moore, Morice, and Baring among the latter. He has been elaborately explained and criticised in Schmidt's *Pindar's Leben und Dichtung* (1852); while his relation to lyric poetry in general forms the subject of Villemain's brilliant *Essais sur le Génie de Pindare et sur la Poésie Lyrique* (1859). The best editions are those of Böckh; of Disson, re-edited by Schneidewin; and of Hartung.

PINDAR, PETER. See WOLCOT.

PI'NDUS, anciently the name of a chain of mountains in Greece (q. v.).

PINE (*Pinus*), a genus of trees of the natural order *Coniferae*. The Linnean genus includes all kinds of Fir, Larch, and Cedar; but as now limited, the genus *Pinus* is distinguished by monocious flowers, and woody cones with numerous two-seeded scales, the scales having an angular truncated apex. The leaves are linear and very narrow, of a very dark-green color, growing in clusters or in pairs, and surrounded by scarios scales at the base. To this genus belong many noble and useful trees. They mostly grow in mountainous or other exposed situations, and their narrow leaves are admirably adapted to evade the force of winds, which produce in the tops of pines a peculiar sound, much noticed by the ancient poets, more soft and continuous than in trees of richer foliage. Most of the pines are more or less social, one kind often covering a considerable tract; some of them clothing the sides and even the summits of mountains with magnificent but sombre forests; some growing in lower situations, on otherwise unproductive sandy grounds, as the *Pine Barrens* of North America. The pines growing in the most barren soils, or in the coldest climates and most exposed situations, are often very small; and although very unlike any other shrubs or bushes, are scarcely to be called trees. Pines are widely diffused over the northern hemisphere, being found on mountains within and near the tropics, and in the colder temperate and the arctic regions descending to the level of the sea.

The SCOTCH P. or SCOTCH FIR (*P. sylvestris*) is the only species indigenous to Britain. It has leaves in pairs, about an inch and a half long; the cones about the same length, obtuse, and with unarmed scales. On very poor soils and at great elevations it is reduced to a kind of shrub, but in favorable situations it becomes a lofty tree. A plank five feet and a half in diameter has been obtained from a Scottish forest. The Scotch P. is of quick growth, but has been known to attain the age of 400 years. Its head is somewhat conical or rounded, and the lower branches die off as the tree grows, leaving the older trees bare of branches for the greater part of their height; but it is more apt to send off large branches than most of the *Coniferae*. There are still native forests of Scotch P. at Braemar and elsewhere in the Highlands of Scotland; and even in the south of Scotland noble trees are to be seen which, probably, were not planted by man. The Scotch P. is not indigenous to the south of England, but having been introduced, is spreading rapidly and spontaneously, along with the Pinaster, in some of the heath and other unfertile tracts. Immense forests of it exist in some countries of Europe, in some of which it is mingled with the Spruce Fir. In the middle and north of Europe and of Asia, it is found even in plains near the level of the sea, especially where the soil is somewhat sandy; in the south of Europe it grows only on mountains. Its timber is highly valuable, being very resinous and durable, and is the *Red Deal* or *Red Pine* used in house and ship-carpentry. There is very great difference, however, in the timber of Scotch P. growing in different soils and

situations, rich soils and sheltered situations being unfavorable to the quality of the timber, which becomes white, soft, and comparatively worthless; and there exist several varieties of Scotch P., some of which yield timber very superior to others.

Many plantations in Britain have, unfortunately, been made of inferior kinds. One of the best varieties is that which forms the northern Scottish forests, often designated *Braemar P.* by nurserymen. It is remarkable for its very horizontal branches, and is therefore sometimes called *P. horizontalis*.—The Scotch P. is not only valuable for its timber, which is available for some purpose at every stage of its growth, but on account of other products. Common Turpentine is in great part obtained from it, and much Tar, Pitch, Resin, and Lamp-black. See these heads. Oil of Turpentine is sometimes distilled from the cones, and even from the leaves; the leaves have also been used in Germany for the manufacture of a substance resembling tow, and called *Waldroelle* (Forest Wool), suitable for stuffing cushions, &c. The resinous

Braemar Pine.

roots are dug out of the ground in many parts of the Highlands of Scotland, and being divided into small splinters, are used to give light in cottages instead of candles. Fishermen, in some places, make ropes of the inner bark, which is applied to a very different use, when most soft and succulent in spring, by the Kamtchatdals and Laplanders, being dried, ground, steeped in water to remove the resinous taste, and used for making a coarse kind of bread.—The DWARF P. (*P. Pumilio*, or *P. Mughus*) is found on the Alps and Pyrenees, its trunk often lying on the ground, although sometimes it appears as a bush or low tree. The recumbent trunks are called *Krummholz* (Crooked-wood) and *Knienholz* (Knee-wood) by the Germans.—The leaves are in pairs, very like those of the Scotch P., but a little longer; the cones are also similar.

From the young shoots an oil resembling oil of turpentine is obtained by distillation, which is a kind of universal medicine among the peasantry of Hungary, as is also the resin spontaneously exuding from the tree, which is known as *Hungarian Balsam*.—The BLACK P., or BLACK FIR (*P. nigricans*, or *P. Austriaca*), is another species closely allied to the Scotch P., but remarkable for its very long leaves. It is a native of Austria. It abounds in resin more than any other European tree.—To the same group of pines belongs the SEASIDE or TAURIAN P. (*P. Pallasiana maritima*, or *Taurica*), which also affords resin in great quantity, and of a very pleasant odor. It is found in many parts of the south of Europe. Its timber is of little value; but great part of the turpentine of the *Landes* and other maritime districts of France is obtained from it. It yields also part of the *Burgundy Pitch* of the apothecaries' shops.—The ALEPPO P. (*P. Halepensis*), a native of the south of Europe, Syria, &c., is a very graceful tree of moderate size, with leaves in pairs and slender. It yields a liquid resin or turpentine, which is extracted from it in Provence and elsewhere, and sold as *Venice Turpentine*. The wood is extensively used in the Levant for shipbuilding.—The LARICIO (*P. Laricio*) has leaves in pairs, lax, and 4–8 inches long, cones 2–4 inches long, with the scales slightly pointed. It is often called the CORSICAN PINE. It grows on the shores of the Mediterranean Sea, and is valuable both for its timber and for its resinous products. In the island of Corsica, it frequently attains the height of 140 feet. It grows well in sandy soils, and has been made particularly useful for preventing the drifting of the sand, and turning to account the otherwise useless tracts between the mouths of the

Garonne and the Adour in France, thus also preserving valuable lands which the sand threatened to overwhelm.—The **PINASTER** or **CLUSTER PINE** (*P. Pinaster*) is another of the most important European species. It has cones in whorls of 3, 4, or even 8 together, 4–6 inches long, leaves in pairs, and very long. It is found on the shores of the Mediterranean, and also in the Himalaya and in China.

It has been used in France to a great extent, in the same way as the Laricio, for covering waste sandy tracts. The timber is of inferior quality, but great quantities of resin are procured from it. It yields *Bordeaux Turpentine*.—The **PYRENEAN P.** (*P. Pyrenaica*) is a majestic tree, a native of the Pyrenees, and producing very fine timber.—The **CALABRIAN P.** (*P. Bruttia*) somewhat resembles the Pinaster.—The **STONE P.** (*P. pinea*) a tree with a broad umbrella-shaped head, a form often seen also in the Scotch fir, forms a characteristic feature of the scenery of the Mediterranean, and is very often introduced in paintings. It

Stone Pine (*P. Pinea*).

is the *Pinie* of the Germans, the *Pignon* of the French. The leaves are in pairs, 4–5 inches long; the cones very large, ovate, and obtuse. The seeds, which do not ripen till the fourth year, are large, abound in a fixed oil, and when fresh have a sweet taste resembling that of almonds. They are used in Italy and other countries in the same way as almonds and pistachio nuts for the dessert, in various dishes, also in emulsions, &c., under the names of *pinies*, *pinioles*, and *pignons*. The use of them, however, is almost entirely confined to the countries in which they are produced, as they very soon become rancid. They are sometimes imported into London in the cone, in which way they can be kept longer, but the cost of importation is much increased. The wood of this tree is very useful and beautiful. It yields resinous products only in small quantity.—The **CEMBRA P.**, or **SWISS STONE P.**, which grows in the central parts of Europe and the south of Siberia—a stately tree, with the lower branches more persistent than they are in most pines, and rigid leaves in groups of three to five—also produces eatable seeds (*Cembra Nuts*), which, although they are extracted with difficulty, are much used. The cuticle contains a resinous juice; but in Siberia, this fruit is so much prized, that noble trees are often cut down to obtain it. The Cembra P. yields a pellucid, whitish oil, resembling oil of turpentine, and known as *Carpathian Balsam*.

North America produces many species of P., some of them very beautiful and very valuable. Besides those long known, and which are found in the states and colonies near the Atlantic, a number of the noblest species of this genus have, since the commencement of the present century, been discovered in California and the north-western parts of America.—The **RED CANADIAN P.** (*P. resinosa*) is found from Canada to the Pacific, but does not reach far south in the United States. It is the **YELLOW P.** of Canada and Nova Scotia. It delights in dry and sandy soils, and attains a height of 70–80 feet, with a diameter of two feet at the base, the trunk continuing of uniform diameter for two-thirds of its length. The leaves are in pairs, and are congregated towards the extremities of the branches. The timber is highly esteemed for strength and durability, and furnishes excellent planks for ship-building. It is also used for masts.—Somewhat resembling this in botanical characters, is the **SCRUB P.**, or **GRAY P.** (*P. Banksiana*), generally only 3–10 feet high, which begins to appear in the northern parts of the United States upon high mountains, and is interesting as an arctic species, extending further north than any other.—The **YELLOW P.** (*P. variabilis*, or *P. mitis*)

abounds in the Atlantic States from New Jersey to Virginia. It is a tree of 50–60 feet high, 15–18 inches in diameter at the base, with leaves 4–5 inches long, usually in pairs, but sometimes in threes upon the younger shoots. The timber is very extensively used for ship-building, and is largely exported to Great Britain. At Liverpool it is known as **NEW YORK PINE**.—The **JERSEY P.**, or **SCRUB P.** (*P. niops*), abounds in the lower parts of New Jersey, and thence to the south-west. The leaves are in pairs 1–2 inches long, the cones armed with strong spines. The tree is rarely 30 or 40 feet high. Great quantities of tar are made from it in Kentucky.—The **PITCH P.** (*P. rigida*) is a native of the northern and middle parts of the United States, often growing in great miry swamps, and attaining a height of 70–80 feet, and a diameter of two feet at the base. The leaves are in threes, varying much in length, as the cones do in size. Immense quantities of it are used for fuel. Tar and lamp-black are sometimes made from it.

The **LOBLOLLY** or **OLD FIELD P.** (*P. Taeda*) grows in dry and sandy soils in the lower parts of the Southern States, often occupying lands exhausted by cultivation. Vast tracts never cultivated, in the Southern States, are *Pine Barrens*, in great part covered with this species of pine. It attains a height of 80 feet and upwards, and has a wide-spreading crown. The leaves are 6 inches long, in threes, sometimes in fours on young branches; the cones four inches high, with strong spines. The timber is not of much value.—The **LONGLEAVED P.**, or **SOUTHERN P.** (*P. palustris*, or *P. Australis*), is perhaps the most important of North American forest trees. It furnishes the greater part of the tar, resin, pitch, and turpentine used in the United States. The timber is also very valuable, and is much used for ship-building. In England and the West Indies, it is known as **GEORGIA PITCH PINE**. The tree attains a height of 60–70 feet, and a diameter of about 16–18 inches; the leaves are in threes, and about a foot long; the cones 7–8 inches long, and 4 inches in diameter, with small spines. The seeds are sometimes eaten.—The **WEYMOUTH P.**, or **WHITE P.** (*P. Strobus*), attains a height of 150 feet, and a diameter of 5 feet and upwards. It has lax sub-triangular leaves in groups of five; and pendulous cones 4–5 inches long, with thin smooth scales. It is frequently planted in Britain and on the con-

Lambert's Pine (*P. Lambertiana*).

tinent of Europe for its beauty. In its native country, it abounds chiefly from lat. 47° to lat. 43°, and southward on the Alleghanies. The timber is not strong, but easily wrought and durable.—Of the species belonging to the north-western parts of America, one of the most magnificent is *P. Lambertiana*, which is found on the Rocky Mountains, between lat. 40° and lat. 43°, chiefly in sandy soils. It attains a height of 150–200 feet, and a diameter of 7 feet and upwards, almost to 20 feet.

The trunk is remarkably straight, and destitute of branches for two-thirds of its height; the leaves in fives, the cones upwards of a foot long. The timber is white, soft, and light; and the tree produces great quantities of a pure amber-colored resin, which, when the wood is partly burned, is changed into a somewhat saccharine substance, used by the natives as a substitute for sugar. The seeds are eaten either roasted or pounded into coarse cakes.—*P. flexilis* is found on the Rocky Mountains, near the headwaters of the Arkansas, and occurs almost to the limit of perpetual snow. It has a dense crown, formed of numerous and remarkably flexile branches. The leaves are in fives. The seeds are used as food by hunters and Indians.—*P. ponderosa*, another

native of the Rocky Mountains, is a magnificent tree, remarkable for the heaviness of its timber, which almost sinks in water. The leaves are in threes, and 9–14 inches long.—*P. Sabiniana*, *P. Coulteri*, and *P. insignis*, are also noble species from the west of North America. The Himalaya Mountains abound in pines, some of which rival in magnificence those of North-west America. The BHOTAN P. (*P. excelsa*), much resembling the Weymouth P. in its botanical characters, and attaining a height of 90–120 feet, abounds in Bhotan, although it is not found in the neighboring countries of Sikkim and Nepal. The wood is highly valuable, being durable, close-grained, and so resinous as to be used for flambeaux and candles.—The CHEER P. (*P. longifolia*) of India is a tree of remarkable and most graceful appearance; with leaves in threes, very long, very slender and generally pendulous. It is abundant on the crests of hills in the lower Himalaya, growing at a lower elevation than the other pines. It is cultivated in some parts of India as an ornamental tree. It is much valued for its resin.

The wood is used in India as a substitute for European deal.—The KHASIA P. (*P. Khasiana*) is peculiar to the Khasia Mountains, and has very much the general appearance of the Scotch pine.—*P. Gerardiana*, a species with leaves in threes, is a large tree, a native of Nepal. The seeds are eatable.—The Mountains of India and the north-western parts of America produce numerous other species; Mexico has a number of very fine ones peculiar to itself; the mountains of St. Domingo have one; the Canary Islands have one; China and Japan also have some. Most of those which have been named, and a number of others, are now readily to be procured in nurseries in Britain, although some of them only at prices which prevent any attempt at extensive plantation. Some wealthy noblemen and gentlemen devote a portion of their grounds to a collection of different kinds of P., called a *Pinetum*. A few foreign species have become pretty common in plantations. Most of the pines are quite hardy in Britain, but this is not the case with the Cheer P. and some of the Mexican species. The name P. is often popularly extended, and even in scientific works, to other *Coniferae*.

PINE-TIMBER.—This term is in general use for the timber of the pine-tribe (see *CONIFERÆ*), and is not confined to that of the genus *Pinus*, but embraces the wood of species of *Abies*, *Larix*, *Araucaria*, *Dammara*, &c. From the Baltic ports we receive red and white pine, or deal timber. The former is yielded by the Scotch Fir (*Pinus sylvestris*), and the latter by the Spruce Fir (*Abies excelsa*). These two, with the Larch (*Larix Europæa*), yield the greatest part of the pine-timber of Europe. Next in importance to these is the pine-timber of the British North American colonies, which is chiefly yielded by the Weymouth or White Pine (*Pinus Strobus*), although, doubtless, the wood of other coniferous trees is often substituted for it. It makes excellent masts; but is not so serviceable for large timbers, as it is subject to dry-rot. Of white pine, the Dominion of Canada exported, in 1876, 289,441 tons, valued at £613,179; and 37,040 tons red pine, worth £62,532; besides large quantities of pine in the form of battens or staves and deal. The wood has a peculiar odor.

The celebrated pitch-pine of Savannah, in the Southern States, is the produce of *Pinus rigida*. It is much used for ship's masts and yards, and for all purposes requiring great strength and durability, in both of which qualities it excels most others of its kind. The kinds above mentioned are those which constitute the greater part of the pine-timber used in ship and house-building, carpentry, &c., in Great Britain. In France, the timber of the Corsican Pine (*Pinus Laricio*) and the Seaside Pine (*Pinus pinaster*) are greatly used. In Italy, the pine-timber is chiefly yielded by the Stone Pine (*P. pinea*) and the Calabrian Pine (*P. Bruttia*; that of Spain is from the Pyrenean Pine (*P. Pyrenaica*). In Germany, and especially in Austria, the Black Pine (*P. Austriaca*) furnishes the greater portion; but the fine-grained, soft white pine, or deal, so much used for sounding-boards of musical instruments, is the wood of the Silver Fir. See FIR. The trade in this timber is very great, for not only do the Germans use it almost exclusively in their vast toy-manufactories and for lucifer-matches, but considerable quantities are exported. The finest is cut in the forests of Bohemia, where large establishments are formed for dressing and preparing the wood for various purposes.

The timber of the Norfolk Island Pine (*Araucaria excelsa*) is sometimes imported for making ships' masts, as several other kinds of pine-timber are imported from time to time, but those mentioned form the great staples of the timber-trade. The chief value of this class of timber-woods is in the combination of lightness and strength with softness of texture and ease in working with ordinary tools; they constitute, in fact, the principal materials of our builders, and are more used than all other kinds of wood together. Much confusion prevails as to their common designations, for in this country alone, *fir*, *pine*, and *deal* are terms applied to all and each of them, according to the caprice of the individual. The two first names are used because the material is derived from one or other of those genera; but the last is a

misnomer altogether, as the term deal belongs only to pieces of fir or pine timber cut to particular sizes: they are three inches in thickness, nine inches broad, and of variable length; if of less width they are called battens.

PINEAL BODY, is a small reddish-gray body, of a conical form, and deriving its name from its resemblance to the fruit of the pine. It rests upon the corpora quadrigemina of the brain, in front of the cerebellum. It is about four lines in length, and from two to three in width at its base. It is larger in the child than in the adult, and in the female than in the male. It consists chiefly of gray matter, and in its base is a small cavity, which contains a transparent viscid fluid, in which are granules composed chiefly of phosphate and carbonate of lime, and termed *acervulus cerebri*. This organ was regarded by the ancients as the seat of the soul.

PINE-APPLE, or ANANAS (*Ananassa sativa*) a plant of the natural order *Bromeliaceæ*, highly esteemed, and much cultivated for its fruit. The fruit is a *sorosis*, formed by the calyces and bracts of a close spike of flowers, becoming succulent and combined. This is the distinctive character of the genus *Ananassa*. The P. has a number of long, serrated, sharp-pointed, rigid leaves, springing from the root, in the midst of which a short flower-stem is thrown up, bearing a single spike of flowers, and therefore a single fruit. From the summit of the fruit springs a crown or tuft of small leaves, capable of becoming a new plant, and very generally used by gardeners for planting; the P., in cultivation, being propagated entirely by crowns and suckers, as, in a state of high cultivation, perfect seed is almost never produced. The P. is a native of tropical America; it is found wild in sandy maritime districts in the north-east of South America, but it has been very much changed by cultivation. It has also been gradually diffused over tropical and subtropical countries, and not only as a cultivated plant, for it is fully naturalized in many parts both of Asia and Africa. It delights in a moist climate, and consequently does not succeed well in the dry climate of the south of Italy, although the warmth is sufficient.

The first particular account of the P. was given by Oviedo in 1535. It was in Holland that it first began to be cultivated in hot-houses; but it was introduced into England in the end of the 17th c., and its cultivation rapidly became general in the gardens of the wealthy. It is only since the peace of 1815 that it has ceased similar attention in continental Europe. Great care is requisite in the cultivation of the P., which, without it, is generally fibrous and coarse, with little sweetness or flavor; and with it, one of the most delicate and richly flavored of fruits. Its size also very much depends on cultivation. The size varies from 2½ lbs. to 12 lbs. in weight. The pine-apples grown in British hot-houses are generally much superior to those of the West Indies, because the latter grow almost or altogether without cultivation; but the importation of pine-apples from the West Indies having now been carried on to a considerable extent, and promising to add to the sources of wealth for these colonies, has led to greater care in cultivation there, and consequent improvement of quality.

In the cultivation of the P. in Britain, a tropical heat must always be maintained. It is generally cultivated in hot-houses specially appropriated to it, called *Pineries* or *Pine-stoves*; sometimes also in flued pits; and sometimes even without fire-heat, in frames continually supplied with fresh tanners' bark and dung. The universal practice, till of late, was to grow the plants in pots, plunged to the requisite depth in tanners' bark or other fermenting matter, and these were transferred from one house or one compartment to another, according to their stage of advancement; three years' culture being deemed requisite from the planting of a crown or sucker to the production of the ripe fruit; but the P. is now often planted in beds, and fruit of the best quality is sometimes obtained in fifteen months. The best soil is a rich and rather sandy loam. It is often formed from the turf of old pastures, with dung, peat, sand, &c., thoroughly mixed. Ventilation must be freely allowed from time to time, but care must be taken to keep the atmosphere moist. A P. which has borne fruit is thrown away as useless.

There are many varieties of the P. in cultivation. Of these, some are referred by some botanists to distinct species. But the greater number of varieties are universally referred to *A. sativa*, and differ in the more or less spiny serratures of the leaves, the globular, cylindrical, or pyramidal fruit, its size, &c.

A spirituous liquor (*Pine-apple Rum*) is made from the P. in some warm countries.

The use of the fibre of the P. is noticed in the article *BROMELIACÆÆ*.

PINE-CHAFER, or PINE-BEETLE (*Hylurgus piniperda*), a small coleopterous insect of the family *Xylophagi*. See *BARK-BEETLE*. It is often very destructive to Scotch firs in rich soils and low situations, attacking the young terminal shoot in summer, and soon eating its way into the heart, which it proceeds to excavate so as to convert the shoot into a tube. Pines growing

in open situations are little liable to the attacks of this insect; and trees of thirty feet in height, or upwards, are very rarely attacked. The insect is about the size of a seed of the Scotch fir, and of a black or dark-brown color.

PINE-FINCH, or **PINE GROSBEEK** (*Corythus*), a genus of birds of the family *Fringillidae*, nearly allied to Bullfinches and Crossbills, the bill nearly resembling that of the former, but the tongue very similar to the tongue of the crossbills, with the same peculiar bone articulated to the hyoid bone. See **CROSSBILL**. One species, the **COMMON P.** (*C. enucleator*), is a very rare visitant of Britain, but is abundant in many of the northern parts of Europe, Asia, and America. It is larger than a bullfinch, but much resembles the bullfinch in form, wings, tail, &c. The general color of the male is red. This bird frequents pine-forests, and associates in flocks in winter. It is easily tamed. Its song is rich and full.—There are other species in the northern parts of the world.—The name **P.** is given in North America to a very different and much smaller bird (*Carduelis pinus*).

PINEL, PHILIPPE, a celebrated French physician, was born 20th April 1745, at Saint-André, in the department of Tarn, France; and after receiving a good classical education at the college of Lavaur, removed to Toulouse, where he studied medicine, and took his degree in 1773. He continued his medical studies at Montpellier, maintaining himself meantime by teaching mathematics; and in 1778 removed to Paris, where he acquired some reputation by a translation into French of Cullen's *Nosology* (1785), and the works of Baglivi (1788), and also by some *Memoirs* on subjects connected with zoology and comparative anatomy. Having applied himself with success to the study of mental alienation, he was charged, in 1791, to make a report on the insane inmates of the Bicêtre, became chief physician of this institution in 1793, and in 1795, was chosen to the same office at the Salpêtrière (a similar asylum, but for females). In the latter institution, **P.** commenced a class of clinical medicine, which he continued after his appointment to the chair of Medical Physics and Hygiene, and subsequently that of Pathology, at the School of Medicine in Paris. He was admitted as a member of the Institute in 1803, and died at Paris, 26th October 1826. His most valuable works were his *Traité Médico-philosophique de l'Aliénation Mentale* (1791), and *La Nosographie Philosophique* (1798), with its commentary, *La Médecine Clinique* (1802). **P.** gained for himself undying fame by his reformation of the old barbarous methods of treating the insane. The physicians brought up under the old system were not ashamed to offer a vigorous opposition to **P.**'s philanthropic opinions; but he fortunately succeeded in thoroughly establishing their correctness, and his system in a few years prevailed all over the whole of Europe.

PINERO'LO, or **PIGNEROL**, a town in the north of Italy, on the Clusone, at the entrance of the valley of Perosa, in the province of Turin, and 23 miles by railway south-west of the city of that name. It was formerly strongly fortified, and was the residence of the rulers of Piedmont. It contains a new cathedral, a bishop's palace, seminaries, barracks, &c. The ruins of the *citadel*, for some time the prison of the *Man with the Iron Mask* (q. v.), are still to be seen on the hill of St. Brigide. Broad-cloth, paper, leather, iron, and silk, are manufactured. Pop. (1872) 11,832.

PINE-WOOL. Several attempts have been made of late years to utilize the leaves of pine and fir-trees, which are cut down in vast numbers for their timber only. The leaves contain a considerable quantity of fine vegetable fibre, which, when separated, has much the appearance of cotton. In Germany, several works have been established for preparing this fibre, and fitting it for various applications; and under the name of pine-wool it is now sold for stuffing cushions, making wadding, &c. The principal manufacture is near Breslau in Silesia, where it was long carried on by the inventor, Herr Pannewitz.

PINEY TREE. See **CALOPHYLLUM**.

PINEY-VARNISH. See **DAMMAR**.

PINGUI'ULA. See **BUTTERWORT**.

PINHOEN, OIL OF. See **PHYSIC NUT**.

PINK (*Dianthus*), a genus of plants of the natural order *Caryophyllaceæ*, of which there are many species, annuals and perennials, with beautiful and often fragrant flowers, chiefly natives of Europe and the temperate parts of Asia. The calyx is tubular, 5-toothed, with two or four scales at the base; there are five petals suddenly contracted at the throat of the corolla into a linear claw. There are ten stamens, and one germen with two styles. The capsule is cylindrical, and one-celled. The exquisite beauty of the flowers has attracted admiration in all ages; and some of the species have long been much cultivated in gardens, particularly the **GARDEN P.** and **CARNATION** (q. v.), which are often referred to one original, the **CLOVE P.** (*D. caryophyllus*), a native of the south of Europe, growing wild on rocks and old walls, and naturalized in some places in the south of England; whilst some

botanists refer the garden pinks in part to the **MAIDEN P.** (*D. deltoides*), a pretty common British species, and those called Pheasant-eye pinks to the **FEATHER P.** (*D. plumarius*), a native of some parts of continental Europe, differing from the **Clove P.** chiefly in having the leaves rough on the margin, and the petals bearded and much cut. Nearly allied to them is *D. superbus*, found in moist places in some parts of Europe, and not unfrequently to be seen in flower-borders. It has very fragrant flowers. All the varieties of Garden **P.**, whatever their origin, have been much changed by cultivation, and careful cultivation is requisite to preserve them in perfection. Both single and double pinks are generally propagated by *pipings*, which are short cuttings of the younger shoots. They are also sometimes propagated by layers. A rich loamy soil is the best for pinks. The **Clove P.**, in a wild state, has flesh-colored flowers. The leaves are linear-awl-shaped, grooved, and glaucous.

The **Maiden P.** is a small much branched plant, growing in grassy places, on gravelly and sandy soils; it has rose-colored flowers spotted with white, and a white eye encircled by a deep purple ring.—The **Depthord P.** (*D. Armeria*) and the **CLUSTERED P.**, or **CHILDING P.** (*G. prolifer*), also natives of England, differ from these in being annuals, and in having clustered flowers.—The **BEARDED P.**, or **SWEET WILLIAM** (*D. barbatus*), a native of the middle of Europe and the south of France, with lanceolate leaves, flowers crowded in dense clusters at the top of the stem, acuminate bracts, and bearded petals, has long been a favorite garden-flower, still retaining its place alike in palace and cottage gardens. Although perennial, it is sown annually by florists, to secure fine flowers, and there are many varieties, single and double, exhibiting much diversity of color. The **INDIAN P.** or **CHINA P.** (*D. Chinensis*) is now also common in flower-gardens.

The **Clove P.** was formerly regarded as possessing medicinal properties, and was used in nervous maladies.—*Sea P.* is a common name of Thrift (q. v.).

PINK COLORS, very light shades of rose-red color: they are usually produced by extreme dilution of cochineal or carmine, Brazil and Braziletto wood colors, with whitening. Some mineral pinks for oil colors are obtained from preparations of manganese, &c. See **RED-COLORS**. The term pink is also applied to several Yellow Colors (q. v.).

PINKERTON, JOHN, an industrious and learned *littérateur*, was born at Edinburgh, 17th February 1758, and educated at the grammar-school of Lanark, where he was noted for the unusual excellence of his classical attainments, and for his hypochondriacal tendency. He was afterwards apprenticed to a Writer to the Signet, his father refusing to let him proceed to the university; and while engaged in the irksome and distasteful practice of law, he published an *Ode to Craigmillar Castle* in 1776, which he dedicated to Dr. Beattie. In 1780, he went to London, where he settled as a man of letters. Next year, he gave to the public a volume of *Rimes* (as he called his pieces), and a collection of *Scottish Tragic Ballads*, followed in 1783 by a second collection of *Ballads of the Comic Kind*—both of which subsequently appeared under the title of *Select Scottish Ballads*. They professed to be ancient, but many of them were really compositions—*forgeries*, some might say, of **P.**'s own, and would hardly deceive a critical archæologist. In 1784, he published an *Essay on Medals*, which went through several editions, and long held a high place among books on numismatics; and in 1785, *Letters on Literature*, marked chiefly by a novel system of orthography (e. g., the use of a instead of s in forming plurals), intended to soften the harshness of the English language, and which was abused as heartily as it deserved. These *Letters* were, however, the means of introducing him to Walpole, through whom he became acquainted with Gibbon and other literary celebrities. **P.**'s next publication was a most valuable one, *Ancient Scottish Poems never before in Print, from the MS. Collections of Sir Richard Mailand of Lethington, Knight* (2 vols. Lond. 1786).

It was followed in 1787 by his once notable *Dissertation on the Origin and Progress of the Scythians or Goths*, in which, for the first time, appear that grotesquely virulent hatred of the Britanno-Celtic race—Scotch Highlanders, Welsh, and Irish—that reaches its climax in his *Inquiry into the History of Scotland preceeding the Reign of Malcolm III.* (2 vols. Lond. 1790), where he affirms again and again, obviously with the extremest gusto, that the Highlanders are mere 'savages, but one degree above brutes'; that they are just as they were 'in the days of Julius Cæsar'; that 'like Indians and Negroes,' they 'will ever continue absolute savages,' and that 'all we can do is to plant colonies among them, and by this, and encouraging their emigration, try to get rid of them.' But in spite of this extravagant truculence of speech, the *Inquiry* contains a great deal of important matter—rare and curious historical documents, some of which are to be found nowhere else in print. **P.** left England in 1802, and fixed his residence at Paris, where he died 10th March 1826, after a life of hard literary work. His principal publications, besides

those already mentioned, are *The Medallie History of England to the Revolution* (1790); *Scottish Poems* (3 vols. 1792), reprinted from scarce editions; *Iconographia Scotica, or Portraits of Illustrious Persons of Scotland, with Biographical Notes* (2 vols. 1795—1797); *The History of Scotland from the Accession of the House of Stuart to that of Mary* (2 vols. 1797), valuable for its laborious investigation of original materials, but disfigured, in a literary point of view, by an imitation of the grandiose style of Gibbon; *Walpoliana*, a collection of his notes of his friend Horace Walpole's conversation, in 2 vols.; *The Scottish Gallery, or Portraits of Eminent Persons of Scotland, with their Characters* (1799); *Modern Geography* (3 vols. 1802—1807); *General Collection of Voyages and Travels* (16 vols. 1808—1813); *New Modern Atlas* (1809—1815); and *Petralogy, or a Treatise on Rocks* (2 vols. 1811).

PINK ROOT. See **SPIGELIA**.

PINNA, a genus of lamellibranchiate molluscs of the same family with the *Pearl Mussel* (*Aviculidae*), and having a shell of two equal wedge-shaped valves, closely united by a ligament along one of their sides. The mantle is closed on the side of the ligament; the foot is small and conical. The byssus is remarkably long and silky; and by it the species affix themselves to submarine rocks and other bodies, sometimes even to sandy or muddy bottoms. The best known species is *P. nobilis*, a native of the Mediterranean, the byssus of which was used by the ancients for fabrics, but chiefly as an article of curiosity, to which a great value was attached. It is still so used in Sicily and elsewhere. It is very strong and lustrous. The only reason against its more general use is the difficulty of procuring it in sufficient quantity. The byssus of this species is sometimes two feet long, the shell is about the same length. Pinnae are often found in large beds, with only the edges of their shells appearing above the mud or sand. The animal is eaten.

PINNACE (from the Ital. *pinaccia*, a diminutive of *pino*, a ship) was originally a small vessel, usually schooner-rigged, employed as tender to a large ship, for the purpose of communicating with the shore, &c. At present, however, the signification is limited to a large boat carried by great ships. It is smaller than the launch, but larger than the cutters; and is generally rowed 'double-banked,' by from ten to sixteen oars.

PINNACLE, an ornamental termination much used in Gothic architecture. It is of simple form in the earlier periods of the style, having a plain square or octagonal shaft and sloping roof or top, terminating with a finial; but in later examples, the pinnacle is greatly developed, and becomes one of the most varied and beautiful features of the style. It is ornamented with shafts bearing canopies, and niches filled with statues. Pinnacles are most frequently used on buttresses and parapets, and when placed over the former, serve as a deadweight to increase their power of resisting a thrust.

PINNULE, in Botany, a leaflet of a pinnate leaf, or of one which is bipinnate, tripinnate, &c. See **LEAVES**. The term is more frequently used, however, to designate the ultimate divisions of the fronds of ferns, when divided in the same manner.

PINSK, a town of West Russia, in the government of Minsk, surrounded by vast marshes called the Pinsk Marshes, stands on the banks of the Pina, a branch of the Pripiet, 752 miles south-west of St. Petersburg, lat. 52° 7' N., long. 26° 6' E. It was founded in the 12th c., was conquered by the Prince of Lithuania in 1320, was annexed, together with Lithuania, to Poland in 1569, and came at last into the possession of Russia in 1795. The trade of P., chiefly transit, has increased, especially since the opening of the Oghinsky Canal, which connects the Dnieper, and the Black Sea with the Niemen and the Baltic Sea. A very considerable number of ships and barges enter and clear the port. They are laden principally with salt, corn, hemp-seed, iron, glass, tar, tallow, wool, tobacco, and timber. The manufacturing activity of the town is not great. The project for a branch line of railway (55 miles) connecting P. with the main line to Minsk, has already been sanctioned. Of the pop. (1880) 17,718, three-fourths are Jews, and have the trade almost entirely in their own hands.

PINT, a measure of capacity used both for liquids and dry goods, and equivalent to the eighth part of a Gallon (q. v.), or 34·65925 cubic inches. The Scotch pint, still in use, though superseded as a legal measure by the imperial pint, is equivalent to 3·00651 imperial pints.

PINTA'DO. See **GUINEA FOWL**.

PINTAIL, or **PINTAIL DUCK** (*Dafila*), a genus of ducks, of the section with the hind-toe destitute of membrane. The bill is without tubercle at the base, narrow, with laminae not projecting beyond the margin. The tail of the male is long, and tapers to a point.—The **COMMON P.** (*D. acuta*) is a handsome bird, rather longer in shape than most of the ducks; the neck also longer and more slender. It is about equal in size to the mallard. The head is brown, with a white longitudinal line on each side extending

down the neck; the back and sides marked with waving lines of black and grayish-white; the lower parts white; the elongated central tail-feathers black. It is a native of all the northern parts of the world, migrating southwards in winter, and a regular visitant of many parts of the British coasts. It also frequents

Pintail Duck (*Dafila acuta*).

fresh-water lakes and ponds, and is common in winter in the valley of the Mississippi. Its winter range extends southwards to the Mediterranean and the Gulf of Mexico, and even to Africa and the West Indian Islands. Its flight is very rapid and noiseless. It is very much esteemed for the table. It has been tamed, and has bred in confinement.

PIOMBI'NO, a principality now incorporated in the kingdom of Italy, lies along the Italian coast opposite the island of Elba, the greater part of which belonged to it. Its extent was about 132 English square miles; and its population, previous to its incorporation with the rest of Italy, about 25,000. P. was originally a fief of the empire, and, at the end of the 14th c., came into the possession of the family of Appiani, which, after ruling it for nearly 300 years, made way for a new dynasty, the family of Buoncompagni. This latter dynasty was mostly under the suzerainty of the neighboring states of Sardinia and Naples alternately.

In 1801, the Buoncompagni family were expelled by Napoleon, and the principality given to his sister Elisa, the wife of Felice, Prince Baciocchi; but the latter was ejected, and the old dynasty restored, by the Congress of Vienna; the principality being then put under the suzerainty of Tuscany, whose grand-duke indemnified the Buoncompagni for their loss of sovereignty. It is now part of the province of Pisa, in the kingdom of Italy. The strait between P. and Elba is called the 'Channel of Piombino.'

PIONEER, a military laborer employed to form roads, dig trenches, and make bridges as an army advances; and to preserve cleanliness in the camp when it halts. Formerly, the pioneers were ordinary laborers of the country in which the army was, impressed for military purposes; but now such persons are only brought in as auxiliaries, a few men being attached to every corps as a permanent body of pioneers. In the British army, one man is selected, for his intelligence, from every company. These pioneers march at the head of the regiment, and the senior among them commands as corporal. Instead of a musket, each man carries a saw-backed sword, which is at once tool and weapon. Each bears also an axe and two gun-spikes, other necessary tools being distributed among them. There is something rather conflicting between the functions of the pioneers and those of the engineer force.

PIOTRKO'W, since 1867, the capital of one of the 10 governments into which Poland was then divided, is near the Warsaw and Vienna Railway. It is one of the oldest Polish towns; here in the 15th and 16th centuries, diets were held, and kings elected. In 1702, P. was burnt by the Swedes; in 1709, the Russians gained a battle here. Pop. (1880) 18,000.

PIOZZI, Mrs. (née **HESTER LYNCH SALUSBURY**), who cannot be forgotten while the great Dr. Samuel Johnson continues to be remembered, was the daughter of John Salusbury, Esq., of Boivel, in Caernarvonshire, where she was born in the year 1739. Early introduced into the fashionable world of London, she charmed by her beauty and her lively manners; and, in 1763, was married to Mr. Henry Thrale, a rich brewer, with a recognized position in society, and, at the time, one of the members for the borough of Southwark. Her acquaintance with Dr. Johnson, which speedily became an intimacy of the closest and most affectionate kind, began shortly after. Of all Johnson's many friendships, this was perhaps, in certain essential respects, the most valuable to him. To Johnson, widowed and alone, and subject, as he had been throughout, to accesses of a frightful gloomy hypochondria, which made life at times to him an almost intolerable burden, the society of Mrs. Thrale, and of the circle which she gathered around her, was a source of incalculable

solace. Mrs. Thrale in particular, with her warm heart, and bright womanly intelligence was always a comforting presence; and her unfeigned cheerfulness and vivacity enlivened for him many an otherwise cloudy hour. Her married life, though prosperous, was not an eminently happy one, Mr. Henry Thrale, though always a pleasant and kindly gentleman, being no miracle of conjugal virtue. If Johnson owed her much, it may be surmised that the benefit was in some sort reciprocal, and that, by her affectionate reverence and solicitude for her sage, she a little consoled herself for the gentlemanly indifference of her husband. On the death, in 1781, of her husband, Mrs. Thrale retired with her four daughters to Bath, where, in 1784, she married Mr. Gabriel Piozzi, an Italian teacher of music. This *mésalliance*—as it was held—was deeply censured by all her friends, and so unreasonably excited the ire of Dr. Johnson in particular, that a rupture of friendly relations was the result.

In the correspondence between them on the subject, it must be admitted that the lady has much the better of the philosopher, whose tone of unmannerly rudeness gives some countenance to the good-natured suspicion of his friends, that he had an eye to the widow himself. Though the feud was ostensibly healed, the friends never again met; Mrs. P. leaving England for Italy with her husband, and Dr. Johnson dying soon after. Some little time subsequent to his death, she published an octavo volume, entitled *Anecdotes of Dr. Samuel Johnson during the last Twenty Years of his Life*, in which it seemed to the indignant Boswell and others, that her main intention was to take her little feminine revenge on the deceased for his outrage in the matter of Piozzi. This work she supplemented in 1788 by a collection of *Letters to and from Dr. Samuel Johnson*, in 2 vols. 8vo. Of works more properly her own, may be mentioned, *Observations and Reflections made in the course of a Journey through France, Italy, and Germany* (2 vols. 8vo., 1789); *British Synonymy, or an Attempt at Regulating the Choice of Words in Familiar Conversation* (2 vols. 8vo, 1794); and *Retrospection, or a Review of the most striking and important Events, Characters, Situations, and their Consequences, which the last Eighteen Hundred Years have presented to the View of Mankind* (2 vols. 4to, 1801)—books long since utterly forgotten, if ever they were at all read and remembered. Having survived her second husband, her own celebrity, and almost in some sort that of the great Dr. Johnson, with whom her name remains indissolubly connected, Mrs. P. died at Clifton, near Bristol, on the 2d May 1821.

PIPA, a genus of batrachians, in general form resembling frogs and toads, and characterized by the very broad and triangular head, the sides of which are destitute of the glands (*parotoids*) so large in the true toads; the eyes small, and situated near the margin of the lower jaw; the ear concealed beneath the skin; the tongue merely rudimentary; the jaws destitute of teeth; the fore-feet not webbed, but divided into four fingers, each of which divides at the extremity into four small points, these, again, being minutely divided in a similar manner; the hind-feet five-toed and completely webbed; the larynx of the male extremely large—a triangular bony box, within which are two small movable bones for occasionally closing the entrance of the bronchi; the back of the female furnished with numerous cells or pouches, in which the eggs are hatched, and the young undergo all their transformations till they have attained a form similar to that of their parents. These characters are so remarkable as to make the creatures of this genus objects of peculiar interest; but particularly the mode of rearing the young. It was at first supposed that the young were produced in some unusual way in the cells from which they were seen finally to emerge; but this is not the case. The eggs are deposited by the female in the ordinary manner, and are carefully placed by the male in the cells of her back, which close over them. When the young are ready to use their limbs, they struggle out of the cells, to which they never afterwards return. The best-known species of P. is that commonly called the Surinam Toad (*P. Surinamensis*), a native of Guiana and other warm parts of continental America, where it inhabits swamps and ditches, and is occasionally found in damp and dirty corners of houses. It is sometimes seven inches long; its color is brownish-olive above, whitish below; the skin covered with small hard granules, mingled with occasional horny tubercles. The whole aspect of the creature is peculiarly hideous.

PIP, CHIP, or ROUP, a disease of poultry, often very fatal, particularly to chickens and turkey poults. It is very frequent also in young pheasants. Adult birds are, however, liable to it; and when it appears in a poultry-yard, it often attacks many in rapid succession, so that it is regarded as highly contagious. It most frequently occurs in wet or very cold weather, and is generally described as a kind of catarrh, although perhaps it might more accurately be called a kind of influenza. It begins with a slight hoarseness and catching in the breath, which is followed by an offensive discharge from the nostrils and eyes, rattling in the throat, and an accumulation of mucus in the month, forming a 'scale' on the tongue. The communication of the dis-

ease from one bird to another is supposed to take place through the contamination of the water in their common drinking-vessel; and therefore a bird affected with it should at once be removed from the rest. Castor-oil is freely administered by some poultry-keepers. Mrs. Blair, in *The Henwife*, recommends also a medicine composed of half a drachm of dried sulphate of iron, and one drachm of capsicum, made into 80 pills with extract of licquorice, one pill to be given three times a day. This after a certain time is to be followed by another compound of sulphate of iron, cayenne pepper, and butter. The eyes, nostrils, and mouth are to be washed with vinegar. In Wright's *Practical Poultry-Keeper*, it is specially recommended that the diseased birds should be kept warm; they are to be fed on oatmeal mixed with ale, and to get plenty of green food.

PIPE, a measure of quantity commonly employed by Portugal, Spain, France, and in some other countries which trade with these. It is used almost exclusively for wine and oil, and has a particular value for almost each locality. The pipe is called in England a butt, and is equal to two hogsheads, or half a tun. The pipe of Oporto is larger than those of Lisbon and of Spain in the proportion of 93 to 76. There are three different measures of this name in France; and there was formerly a pipe, a measure of capacity for dry goods, in use by the Bretons. But the pipe in England varies with the description of wine it contains; a pipe of port contains 114 imperial gallons; of sherry, 108 imperial gallons; and of madeira, 92 imperial gallons; while the common English pipe contains 126 wine gallons, or 105 imperial gallons nearly.

PIPECLAY is a fine Clay (q. v.), free from iron and other impurities, having a grayish white color, a greasy feel, and an earthy fracture. It adheres strongly to the tongue, and is very plastic, tenacious, and infusible. It is used for the manufacture of tobacco-pipes and white pottery. The localities where it is chiefly obtained are Devonshire, and the Trough of Poole in Dorsetshire. It is also found in various places in France, Belgium, and Germany.

PIPE-FISH (*Syngnathus*), a genus of osseous fishes of the order *Lophobranchii* (q. v.), and of the family *Syngnathidæ*. In this family the form is elongated, there is little flesh, and the body is almost covered with partially ossified plates; the head is long; the jaws are elongated so as to form a tubular snout—whence the names P. and *Syngnathus* (Gr. *syn*, together; and *gnathos*, a jaw); and the males have pouches, variously situated, in which they receive the eggs of their mate, and carry them till they are hatched.

The family *Syngnathidæ* is sometimes restricted to those in

Pipe-Fish (*Syngnathus acus*).

which the egg-pouch of the males is on the tail, and is open throughout its whole length, and the tail is not prehensile. Thus restricted, it contains a number of genera, of which one only, *Syngnathus*, is British.—One of the most common British species is the GREAT P. (*Syngnathus acus*), which is sometimes found in deep water, and sometimes at low tide among the sea-weed in rock-pools. The specimens commonly seen are from 1 foot to 16 inches in length; but this fish is said to attain a length of 2 or 3 feet. Its food, and that of the other species, is believed to consist of small marine animals and the eggs of fishes; and it may be seen slowly moving about, with curious contortions, poking its long snout into every crevice in search of food, and sometimes assuming a vertical position with the head downwards, poking into or stirring the sand. This and the other pipe-fishes show great affection for their young, which are believed to return, on the appearance of danger, to the pouch of their male parent, after they have begun to leave it, and to swim about in the sea.

The name P. is sometimes also given to the fishes forming the family *Fistularidæ* (q. v.), or Flute-mouths, sometimes called *Pipe-mouths*.

PIPERACEÆ, a natural order of exogenous plants, natives almost exclusively of the hottest parts of the globe, particularly of Asia and America. None of them found in cold regions. About 600 species are known, to most of which the name PEPPER is sometimes given, although some are also known by other names.

particularly those of which the fruit is not used as a spice, but of which some part is employed for some other purpose, as Betel, Cubebs, Matico, and Ava. See these heads. But Pepper (*q. v.*) is the most important product of the order. Of the *P.*, a few are almost trees; but they are generally shrubs or herbaceous plants, often climbing. They have jointed stems; opposite whorled or alternate leaves, with or without stipules, and insignificant greenish flowers in slender spikes, unisexual or hermaphrodite, the different kinds generally mingled in the same spike; the flowers without calyx or corolla, but each with a bract, the stamens 2—6, the ovary with one cell and one ovule, and crowned with one or three stigmas; the fruit somewhat succulent, containing one seed.

PIPERINE ($C_{15}H_{19}NO_5$) is an alkaloid possessing very weak basic properties, which is found in the Pepper tribe. It may be obtained by heating powdered pepper with alcohol, which extracts the piperine and some resinous matter, which may be removed by digestion in a solution of potash. It occurs in colorless well-formed prisms, which are insoluble in cold water, but dissolve readily in alcohol and ether. According to Miller, piperine 'has an acrid taste, resembling that of pepper;' while Gorup-Besanez asserts that 'it is devoid of odor or taste, and that, consequently, the well-known properties of pepper are not dependent on it.' On heating piperine with soda-lime, a remarkable oily base, *Piperidine* ($C_{10}H_{17}N$), is obtained, with a pungent odor, resembling both that of ammonia and pepper.

PIPES, or TUBES, are made of various materials and for various purposes. Thus, we have draining-pipes for agricultural and sanitary purposes, made of earthenware, wood, and metal; pipes of various kinds of metals for a great variety of purposes, and Tobacco-pipes (*q. v.*) of various materials. Formerly, wooden pipes were extensively used for conveying water and for draining; but so great an improvement has been effected of late years in the manufacture of metal and earthenware pipes, that they have now become exceedingly rare, and will soon disappear. For agricultural purposes, *drain-tiles* are made of ordinary brick-clay; and owing to the use of machinery in their manufacture, they are produced very rapidly and cheaply. They are of various sizes, but the most general is 15 inches in length by 2½ inches diameter. The operation of the drain-tile machine is to squeeze a continuous length of soft plastic clay through a ring-shape orifice, the center of which is occupied by a core or mandrel of the size of the hollow part of the pipe. Another arrangement of the machine is to cut the pipe to the proper lengths as it passes through, and by means of a traveling-table, to carry them forward to be removed to the sheds, where they are dried, previous to being burned in the kilns.

Earthenware pipes are now made of almost every size, from an inch or two in diameter up to the enormous size of fifty-four inches. They are usually made of fire-clay, and are glazed like common pottery. See the article POTTERY. They are wider at one end, so as to form a socket, as in fig 1, to receive the end of another, and thus form a continuous tube. These are greatly used for the drainage of houses, and for sewerage, for which they are admirably adapted: the inner surface being glazed, as well as the outer, offers no resistance to sedimentary matters, which are

Fig. 1.

Fig. 2.

consequently carried away readily. These pipes are of such great strength, that many small towns in England are now sewered with them almost entirely. Another kind has been introduced for chimney flues. They are also made of fire-clay, but unglazed externally, and so thick, that there is little fear of breaking. They are placed one on another, and are built into the walls of houses, instead of the ordinary chimneys, and in this way save much labor in building, and in this way afford a much more effective, and easily cleaned flue (fig. 2). *Caoutchouc vulcanized* and *gutta percha* are also extensively used for making pipes for a variety of purposes, their flexibility rendering them very useful. *Leathern pipes* are used chiefly for the conveyance of water temporarily, as in the case of fire-engines; they are generally called *hose*. Metal pipes are made of iron, lead, tin, or an alloy of tin and lead, copper, brass, &c. Iron pipes are usually cast, and the manufacture of such pipes has become of enormous extent, in consequence of the vast works, by which almost all large towns in this kingdom and in many foreign states are now supplied with water and gas, the pipes for which are largely exported from Great Britain. A great proportion of the trade in cast-iron pipes is carried on in Scotland. The water-works which supply the great towns of Lancashire have nearly all been furnished with

pipes from Scotland; and the magnitude of the supply can be best understood when it is known that for the Rivington Pike Works, which supply Liverpool, upwards of twenty miles of iron pipes, nearly four feet in diameter, are required. It would be impossible to make a correct estimate, but it has been stated, with great reason for belief, that in Great Britain the gas and water-pipes laid and in use exceed half a million of miles in length.

Pipes made from the ductile metals, such as brass, copper, and tin, are made by first casting an ingot of the metal into the shape shown in fig. 3, with a hole through its length of the same diameter the bore of the pipe is intended to have. Into this is placed an iron rod, called the mandrel (*a*, fig. 4), which exactly fits, and which projects slightly at the tapered end (*b*, fig. 4). It is then brought to the drawing-table, and here the small end with its projecting mandrel is put into a funnel-shaped hole, drilled

through a steel post (*a*, fig. 5), so as to allow the point to be gripped on the other side by a pair of pincers, at the end of a strong chain; the machine-power is then applied to the other end of the chain, and the soft metal and its mandrel are drawn through, the former being extended equally over the surface of the latter, which is then removed, and the length of pipe is complete. Some metals require repeated drawing through holes, getting gradually smaller, and have to be softened or annealed at intervals, as the metal hardens under repeated drawing. In this way, brass, copper, tin, and pewter pipes are made; and a patent has also been taken out for making steel ones; but lead pipes are made of great lengths by squeezing the soft metal through a hole in a steel plate in which there is a fixed core or mandrel projecting, which forms and regulates the size of the bore of the pipe. Pipes are also made from copper, brass, and malleable iron by rolling out narrow strips of metal, and then passing them successively through rollers, which are deeply grooved, and which turn up the edges (fig. 6). A mandrel is then laid in it, as in fig. 7, and it is next passed through double-grooved rollers, which

turn the edges in, and thus form a complete tube round the mandrel. The edges, however, require soldering or welding, if of iron. All boiler tubes used to be made in this way; but the method of drawing has lately been so much improved, that copper and brass pipes, or tubes, as they are frequently called, are now drawn of considerable thickness and diameter.

PIPE-STICKS. It is usual to call the wooden tubes used for some tobacco-pipes by this name; and unimportant as it may at first sight appear what the tube is made of, there is great difference of taste in this respect; and great care is taken by some smokers to get what they consider the choicest material. Perhaps the most prized are the Agriot or Cherry pipe-sticks of Austria. These are the young stems of the Mahaleb Cherry (*Prunus Mahaleb*), which is extensively grown for the purpose in the environs of Vienna. An astonishing amount of care is bestowed on the cultivation of these shrubs, which are all raised from seed. When the seedlings are two years old, they are each planted in a small pot, and as they continue to grow, every attempt at branching is stopped by removing the bud. As they increase in size from year to year, they are shifted to larger pots or boxes, and great care is taken to turn them round almost daily, so that every part is equally exposed to the sun. When they have attained a sufficient height, they are allowed to form a small bushy head, and continue to receive the same attention in daily turning, &c., until they are thick enough in the stem. They are then taken up, and the roots and branches removed, and the stem put by to season. Afterwards, they are bored through, and are ready for use. These pipe-sticks have an agreeable odor, and are covered with a reddish-brown bark, which is retained. Sometimes they are five feet in length, and as smooth and straight as if turned. When of such a length, they command high prices. In Hungary, pipe-sticks made from the stems of the Mock Orange (*Philadelphus coronarius*)

are much used; and the jessamine sticks of Turkey are in great esteem in all countries. Orange and lemon-trees and ebony are also used. The chief recommendation of these materials seems to be in the power of the wood to absorb the oil produced in smoking tobacco, and consequently to render the smoke less acrid. See TOBACCO-PIPES.

PIPI, the name given to the ripe pods of *Cassalpinia Papai* (see CASSALPINIA), which are used in tanning, and are not unfrequently imported along with Dividivi (q. v.), and sometimes separately, but not to any considerable extent, being very inferior to dividivi. They are easily distinguished from the pods of dividivi, not being curved as they are, but straight.

PIPING CROW. See BARITAH.

PI'PIT, TITLING, or TITLARK (*Anthus*), a genus of birds included by Linnæus among Larks (*Alauda*); but now regarded as forming even a distinct family, *Antididae*, which is ranked among the *Dentirostres*, whilst the lark family (*Alaudidae*) is ranked among the *Corvirostræ*. The bill is more slender than in larks; the tips of the mandibles slightly bent downwards and notched. The hind-claw is long, although not so long as in larks, and more or less curved. The plumage resembles that of larks; in habits and motion of the tail, there is a greater resemblance to wagtails. The bill is not strong enough for feeding on grain or hard seeds, and insects and worms are the principal food of pipits. The most common British species is the MEADOW P., COMMON TITLARK, or TITLING (*A. pratensis*), familiarly known in many parts of England and of Scotland as the *Moss-cheeper*. It is found in almost all parts of Europe, and the north of Asia, in Western India, in Japan, and in Iceland. It is a small bird, its color brown of various shades. It frequents heaths, mosses, and pastures; and usually makes its nest on a grassy bank, or beside a tuft of grass or heath. Its song is weak and plaintive, and it generally sings in the air. It is gregarious in winter. The cuckoo is said to deposit its egg more frequently in the nest of the Meadow P. than in that of any other British bird.—A rather larger British species is the TREE P., or FIELD TITLING, which has a shorter claw, and perches on trees, frequenting enclosed and wooded districts. It is a summer visitant of Britain, and most common in the south of England. It occurs in most parts of Europe, in Asia, and the north of Africa.—The Rock P., or SEA TITLING (*A. petrosus*), is to be found on the shores of all parts of Britain and Ireland. It is rather larger than the Tree P., and has a long curved hind-claw. It feeds chiefly on small marine animals, seeking its food close to the edge of the retiring tide.

PI'PPIN (so called probably because raised from the *pip*, or seed), a name given to many varieties of apple, among which are some of the finest in cultivation, as the *Golden P.*, *Ribston P.*, &c. The Ribston P. was long supposed to be an originally English variety, produced at Ribston Hall in Yorkshire, but it is proved to have been introduced from Normandy in the beginning of the 18th century.

PIQUÉ WORK, a very fine kind of inlaying with gold, silver, and other costly materials; it is, in fact, a kind of Buhl-work (q. v.), carried out on a very minute scale. It is only applied to articles of small size, such as snuff-boxes, card-cases, and similar articles.

PIQUET is a small body of men posted at some point beyond the general line of the army or corps, for the purpose of observing the motions of an enemy, or giving timely notice in case of any attack. Piquets are either *outlying* or *inlying*.

PIQUET, a game of cards played between two persons with thirty-two cards—viz., the four honors, and the highest four plain cards of each suit. The cards are shuffled and cut as in whist, and then dealt, two by two, till each player has twelve; and the remaining eight, called the *talon*, or stock, are then laid on the table. The first player must then discard from one to five of his cards, replacing them with a similar number from the talon; and after him, the younger hand may discard if he pleases, similarly making up his proper number from the remaining cards of the talon. The player who first scores 100 wins the game, and the score is made up by reckoning in the following order—carte-blanche, the point, the sequence, the quatorze, the cards, and the capot. *Carte-blanche* is a hand of twelve plain cards, and counts ten for the player who possesses it. The *point* is the greatest number of cards in any suit, or, if the players are equal in this respect, that which is highest in value (the ace counting eleven, each court-card ten, and the plain cards according to the number of pips), and counts a number equal to the number of cards in the suit.

The *sequence* is a regular succession of three or more cards in one suit, and the highest sequence (i. e., the one containing the greatest number of cards, or if the players have sequences equal in this respect, the one of the two which begins with the highest card), if of three cards, counts three; of four cards, four; of five cards, fifteen; of six cards, sixteen, &c. The *quatorze* is a set of

four equal cards (not lower than tens), as four aces, four queens, &c., and the highest quatorze counts fourteen for its holder; but should neither player have a quatorze, then the highest set of three is counted instead, but it reckons only three. The possessor of the highest sequence or the highest quatorze also counts all inferior sequences and quatorzes (including sets of three); while his opponent's sequences and quatorzes go for nothing. The first player reckons his points, and plays a card; the dealer then reckons his points, and follows his opponent's lead, and cards are laid and tricks are taken as in any ordinary card-game. Each player counts one for every card he leads, and the taker of the trick (if second player) counts one for it; the possessor of the greater number of tricks counting ten in addition (the 'cards'), or if he takes all the tricks, he counts forty in addition (the 'capot'). If one player counts thirty—i. e., 29 by his various points, and one for the card he leads, before his adversary has counted anything, he at once doubles his score, reckoning sixty instead of thirty (this is called the 'pique'); and should his score reach thirty before he plays a card, or his adversary begins to count, he mounts at once to ninety (the 're-pique').

PIRACY is robbery on the high sea, and is an offence against the law of nations. It is a crime not against any particular state, but against all mankind, and may be punished in the competent tribunal of any country where the offender may be found, or into which he may be carried, although committed on board a foreign vessel on the high seas. It is of the essence of piracy that the pirate has no commission from a sovereign state, or from one belligerent state at war with another. Pirates being the common enemies of all mankind, and all nations having an equal interest in their apprehension and punishment, they may be lawfully captured on the high seas by the armed vessels of any particular state, and brought within its territorial jurisdiction for trial in its tribunals. The African slave-trade was not considered piracy by the law of nations; but the municipal laws of the United Kingdom and of the United States by statute declared it to be so; and since the treaty of 1841 with Great Britain, it is also declared to be so by Austria, Prussia, and Russia.

PIRÆUS (Gr. *Peiræus*), the principal harbor both of ancient and modern Athens (q. v.). Only a few traces remain of the long walls which formerly united it and Munychia with the capital city. The modern P., which has sprung up since 1835, is a regularly laid-out town, with some good houses and shops, and a handsome stone exchange, built at the expense of the municipality. It was in 1869 connected with Athens by a railway, and it has several spinning factories of recent construction. The harbor, called also Porto Leone or Drakoni, is both safe and deep; but the entrance is narrow. In 1871, the number of vessels which entered the P. was 6206, with a tonnage of 294,338 tons. Pop. (1879) 21,055.

PIRANO, a seaport of Austria, in the markgratdom of Istria, stands on a peninsula in the bay of Largone, 15 miles south-west of Trieste. It contains an old castle, has a port and several dockyards, commodious roads, in which large vessels find safe anchorage, and is the seat of considerable trade and commerce. Among its more important edifices are an interesting Gothic church, a town-house, and a Minorite convent, with a number of good pictures. Wine and oil are made in considerable quantities, and there are salt-works in the neighborhood, which produce upwards of 330,000 cwts. of salt annually. Pop. (1880) 7387.

PIRAYA, or PIRAI, the name given in Guiana to *Serrasalmo piraya*, and other species of *Serrasalmo*, a genus of fishes of the family *Characinidae*, regarded by many as a section of *Salmonidae* (q. v.). The fishes of this genus, of which numerous species inhabit the rivers and other fresh waters of tropical South America, have a compressed and deep body, the belly keeled and serrated with a double row of hard serratures. They are extremely voracious fishes, and not only consume with great rapidity dead carcasses thrown into the water, but attack living creatures very much larger than themselves, biting off the fins of large fishes, and then devouring them at leisure, often mutilating ducks and geese by depriving them of their feet, and venturing to attack even oxen and human beings. The latter, however, make reprisals on them, and find them very good food. *Serrasalmo piraya* seldom exceeds 10 or 12 inches in length, but some of the species attain a considerably larger size. Some of them are very brilliantly colored. The Indians use the teeth for sharpening the arrows, made of the very hard ribs of palm-leaves, which they use for their blow-pipes, and which they sharpen to a very fine point by drawing them across a piraya's jaw, an article with which the Indian of Guiana is always provided; nor does the edge of the teeth soon begin to be worn.

Pirayas are readily taken by a baited hook, and almost any kind of bait will do; but they at once cut through any line, and the line must therefore be eased above the hook in tin-plate. The Indians often shoot them with arrows.

PIRMASENS, a town of the Bavarian Palatinate, and formerly the chief town of the county of Hanau-Lichtenberg, 22 miles west of Landau. In 1880, it had 12,039 inhabitants; chief manufactures, shoes and musical instruments.

PIRNA, a small town of Saxony, stands on the left bank of the Elbe, 11 miles by railway south-east of Dresden. It is surmounted by a hill, crowned by a castle, now used as a lunatic asylum, contains a beautiful parish church, and a number of important benevolent institutions. The manufacture of stoneware employs many hands. Pop. (1880) 11,680.

PISA, one of the oldest and most beautiful cities of Italy, capital of the province of the same name, which formed part of the late grand duchy of Tuscany, is situated on the banks of the river Arno, which intersects the city and is spanned by three noble bridges. P. is situated in 43° 43' N. lat., and 11° 24' E. long. The population was, in 1881, 53,957. It has broad, straight well-paved streets, and several fine squares. Among its 80 churches, the most worthy of notice is the cathedral, or Duomo, begun in 1068, and completed in 1118, with its noble dome, supported by 74 pillars, and its fine paintings, variegated marbles, and painted windows. Near the cathedral stands the round marble belfry known as the Leaning Tower of Pisa, from the circumstance that it deviates about 14 feet from the perpendicular. This celebrated building, which is 180 feet in height, and consists of seven stories divided by rows of columns, and surmounted by a flat roof and an open gallery commanding a splendid view of the surrounding country, was erected in the 13th c. by the German architect Wilhelm of Innsbruck.

The Baptistery, or Church of St. John, opposite the cathedral, an almost equally remarkable structure, was completed in 1162 by Diotisalvi. The main building, which is circular, and raised on several steps, supports a leaden-roofed dome, having a second dome above it, surmounted by a statue of St. John. The beautifully proportioned interior, noted for its wonderful echo, contains a pulpit, which ranks as the greatest masterpiece of Nicola Pisano, various pieces of sculpture, and a large octagonal marble font. The Campo-Santo, or ancient national cemetery, dates from the year 1238, when the Pisans caused earth to be brought from Jerusalem for the graves of the most distinguished citizens of the republic. In 1283, the ground was surrounded by cloisters, the walls of which were adorned by fresco-paintings, now nearly obliterated, although some of these works of art, which are chiefly by Giotto, Veneziano, Orcagni, and Memmi, still retain traces of their original beauty. Among the other public buildings of P., special notice is due to the churches of La Madonna della Spina and San Stefano, both rich in paintings and sculptures, and the latter famous for its organ, the largest in Italy; the grand ducal and Lanfranchi palaces; the Torre della Fame, so called from its being supposed to have been the spot in which Ugolino Gherardesca and his children were starved to death in 1288; the university, founded in 1380, and restored by Cosimo I. de' Medici, which enjoyed a high reputation in the middle ages, and still possesses claims to consideration in its library, botanical garden, observatory, and affiliated schools and art collections, &c. The population of P., which, in the 13th c., amounted to 150,000, had fallen, in the present century, to less than one-sixth of that number; but of late years, trade and industrial arts have made a rapid advance, and the population has increased in proportion. In the neighborhood of P., at the foot of San Giuliano, lie the mineral baths, whose fame was known to Pliny, and which continued through the middle ages to attract sufferers from every part of Italy. The waters, which are rich in carbonic acid and chloride of sodium, are found efficacious in various arthritic and rheumatic affections.

History.—Ancient P., like other Etruscan cities subject to Rome, retained its municipal government, and enjoyed an almost unlimited freedom while nominally under Roman protection; but on the decline of the imperial power, it was compelled to submit in turn to the various transalpine nations, who successively overran Northern Italy. Early in the 11th c., P. had risen to the rank of a powerful republic, whose sway included the then fertile district known as the Maremma di Lerici, and which yielded little more than nominal homage to its suzerain lords, the emperors of Germany. Throughout the 11th c., P. was at the height of its prosperity, and to this period belong most of the splendid monuments of art that still adorn the city. Its troops took part in all the great events of the Holy Land; and its fleet in turn gave aid to the pope in Southern Italy, to the emperor in Northern France, chastised the Moors, and exacted its own terms from the Eastern emperors. In their wars with the Saracens of Sardinia, the Pisans had conquered Sardinia, Corsica, and the Balearic Islands, and for a time maintained their ground against their hereditary enemies, the Genoese; but having sided with the Ghibellines in the long wars which desolated the empire, P. suffered severely at the hands of the victorious Guelphic party. Indeed, the rivalry of the Guelphic cities of Florence, Lucca, and Siena, nearly brought P. to the brink of ruin at the close of the 13th c.;

and after struggling for more than a hundred years against external foes and the internal dissensions between the democratic mob and the Ghibelline nobles, without losing their character for indomitable valor, the Pisans finally threw themselves under the protection of Galeazzo Visconti of Milan. The son of the latter sold the Pisan territory to their greatest enemies, the Florentines, from whose tyrannical rule it was for a time relieved by Charles VIII. of France, who, in 1494, accepted the protectorate of the city. When the French left Italy, the old struggle was renewed; and after a desperate resistance, the Pisans, in 1509, were compelled by hunger to surrender to the Florentine army. The most influential families, as formerly in 1406, emigrated. P., with the rest of Tuscany, became part of the kingdom of Italy in 1860. Since 1868, P. has given its name to an Italian province, containing a population of (1881) 283,269.

PISA, COUNCIL OF, one of the councils commonly reputed by Roman Catholics as oecumenical or general, although some, especially of the Ultramontane (q. v.) school, do not look upon it as such. It was assembled in the time of the great Western Schism, for the purpose of restoring the peace of the church, and the unity which had been interrupted by the rival claims of two competitors for the papacy. The history of this rival claim will be found under the head **SCHISM, WESTERN**. For our present purpose, it is enough to state that the adherents of both the claimants of the see of Rome—those of Gregory XII., as well as those of Benedict—agreed on the necessity of a general council, as the only means of putting an end to the schism; and the rival popes having themselves either evaded or declined the demand, the cardinals of both united in issuing letters of convocation, and in summoning both the claimants to the council so convened. Neither of them complied with the citation; but the council proceeded, nevertheless, to examine and deliberate upon the cause. It was opened at Pisa, March 25, 1409, there being present 22 cardinals, 4 patriarchs, 12 archbishops, 80 bishops, together with representatives of 12 archbishops and 102 bishops, and a vast body of abbots, doctors in theology, and other eminent ecclesiastics. Of the proceedings, it will be enough to say, that after a formal citation of the rival popes to appear within a stated period, the council, on the expiration of that period, proceeded to declare them contumacious, and to examine their respective claims as though they had appeared. The result, after a protracted inquiry, was a decree in the 13th session by which they were both declared schismatics, and their conduct heretical, and calculated to lead the people from the faith; wherefore, since they had violated the solemn engagements made at their respective elections, they were deposed from the papal dignity, and their followers released from obedience.

In the 17th session, the cardinals having first pledged themselves by oath, each, that, if elected, he would continue the sittings of the council, entered into conclave to the number of 24, and unanimously elected Peter Philargi, one of the cardinal priests, and a member of the Franciscan order. He took the name of Alexander V. The council proceeded after his election to pass a number of decrees, for the purpose of giving validity to the acts done on either side during the schism. A vain attempt was made to obtain the submission of the still recalcitrant rivals, and it was resolved that a new council should be held within three years. The authority of this council, like that of the Council of Constance, is alleged, on the Gallican side, as establishing the superiority of a general council over the pope. But the Ultramontanes reply that both these councils, and also that of Basel, must be regarded as abnormal assemblies, called to meet the special emergency of a disputed succession and of a doubtful pope, and that these principles cannot by any means be applied to the ordinary circumstances of the church, or form a precedent by which to estimate the normal relations between a pope whose title is certain and undisputed, and a general council regularly assembled at a time of peace, and in the ordinary circumstances of the church. It cannot be doubted, nevertheless, that the spirit of the fathers of Pisa was the same which ran through the succeeding assemblies of Constance and Basel, and found its permanent representation in the Gallicanism (see **GALLICAN CHURCH**) of later centuries.

PISCA'TAQUA, a river of about 80 miles in length, which forms the southern part of the boundary between Maine and New Hampshire, U.S., and empties itself into the Atlantic, forming at its mouth the excellent harbor of Portsmouth.

PISCICULTURE, or **FISH-CULTURE**, the breeding and rearing of fishes, in order to the increase of the supply for food. Hitherto, it has been almost entirely limited to fresh-water fishes; nothing having been done as to sea-fishes but by legislation—chiefly in the case of the herring—to prevent the destruction of the very young fish, and that not, apparently, to much advantage. Ponds for sea-fishes have, indeed, been sometimes constructed, advantage being taken of natural circumstances favorable for the purpose; the ancient Romans had such ponds, and some have been made on different parts of the British coast; fishes

being caught in the open sea and placed in them to be fed and fattened for the table. Such ponds, however, are of little real utility. That the Romans succeeded in keeping sea-fishes in fresh-water ponds, as has been asserted, must be regarded as mere fable, or as an exaggeration, founded on the power which a few fishes have of adapting themselves both to fresh and salt water. But it may be doubted if in modern times sufficient advantage has been taken of this power.

Ponds for fresh-water fishes have been common from a very remote antiquity. It appears from Isaiah, xix. 10, that they were used in ancient Egypt. In the times of Roman luxury, almost every wealthy citizen had fish-ponds. The Chinese have long bestowed more attention on pisciculture than any other nation, and with them it is truly a branch of economy, tending to the increase of the supply of food and of the national wealth; not merely, as it seems to have been among the Romans, an appliance of the luxury of the great. In some countries of modern Europe, this branch of pisciculture is also prosecuted to a very considerable extent, particularly in Germany and Sweden, and of late years in France, in order to the supply of fish for the market.

In Britain it has never been systematically prosecuted, or for any important purpose; the country-seats of the nobility and gentry being, indeed, generally provided with fish-ponds, but in most cases rather as ornamental waters than for use. In the northern parts of Britain, trout, perch, and pike are almost the only fish kept in ponds; in England, they are often stocked with carp and tench, and are turned to much better account than in Scotland. In Germany, ponds carefully attended to are found very productive and remunerative. There can be no doubt that in Britain, also, many a piece of land at present very worthless, might easily be converted into a pond, and made to yield large quantities of excellent fish; but such a thing seems almost never to be thought of.

In the construction of ponds, or *stews*, for fish, it is recommended to have, if possible, a succession of three ponds on the same rivulet, with sluices, by which they can be dried, so that the fish may be easily taken when required, the different ponds being in part intended for fish of different ages. But all this must be very much regulated by local circumstances. It is of more importance to note that the margin should be shallow, so that there may be abundance of reeds and other water-plants, and that only a small part of the pond should be too deep for the growth of pond-weeds (*Potamogeton*). Much depends on the soil of the neighborhood as to the supply of food, and consequently the growth of fish and productiveness of the pond. A stony bottom is very advantageous to perch and trout ponds; and in designing these, care should be taken to provide places of shelter for the fish, more especially if the pond be a shallow one, as trout and perch are easily killed by the glare of the sunshine. Ponds for pike must be larger than is necessary for any other fish known to British pisciculture: an extent of at least six acres is desirable.

A nursery for minnows may be established with great advantage in connection with a fish-pond, as they afford most acceptable food to perch, pike, and trout. But in a pond where carp and tench are expected to spawn, the presence of minnows is very undesirable. It is often impossible to provide a pond with a place suitable for the spawning of trout, for which a gravelly stream with a quick current is necessary; but for perch, pike, carp, or tench, the pond itself is sufficient, and the stock, once introduced, is kept up without replenishing. Indeed, it is recommended that a pond stocked with carp should also be stocked with pike, that the excessive multiplication of the carp may be checked, which would otherwise prevent the fish from growing rapidly or to a good size. Private ponds and stews in which country gentlemen breed fish for the use of their own tables, as well as similar places attached to monasteries and other religious edifices, in which fish were grown for fast-day uses, were at one time common enough throughout Great Britain and Ireland. It is probable that some of our rarest fishes were introduced into this country during the old monastic times, such as the Lochleven trout, the vendace, &c.

The greatest improvement in pisciculture, and a most important branch of it, to which the term is often restricted, is the breeding of fish in artificial breeding-places, from which not only ponds but rivers may be stocked; or the art of fecundating and hatching fish-eggs, and feeding and protecting the young animals till they are of an age to secure their own food, and protect themselves from their numerous enemies.

Modern pisciculture is the revival of an old art well known to the ancient Italians, but which had fallen into abeyance for a number of centuries. The art of breeding and fattening fish was practised by the luxurious Romans, and many stories are told about the fanciful flavors which were imparted to such pet fishes as were chosen for the sumptuous banquets of Lucullus, Sergius Orata, and others. The art had doubtless been borrowed from the ingenious Chinese, who are understood to have practised the art of collecting fish-eggs and nursing young fish from a very early period. Fish forms to the Chinese a most important article of diet;

and from the extent of the water-territory of China, and the quantities that can be cultivated, it is very cheap. The plan adopted for procuring fish-eggs in China is to skim off the impregnated ova from the surface of the great rivers at the spawning season, which are sold for the purpose of being hatched in canals, paddy-fields, &c.; and all that is necessary to insure a large growth of fish is simply to throw into the water a few yolks of eggs, by which means an incredible quantity of the young fry is saved from destruction, as a large percentage of the young of all fish die for want of food. Although all kinds of fish are enormously fecund, it is well known to naturalists that only a small percentage of the eggs ever come to life, and of the young fish, very few ever reach the table as food. So many of the eggs are destroyed by various influences, and so many likewise escape impregnation, that if we are to keep up our fish supplies, pisciculture, or protected breeding, becomes absolutely necessary.

Commercial pisciculture as at present carried on, owes its origin to the French, the art having been first put in practice by M. Remy, a poor fisherman who gained a living by catching fish in the streams of La Bresse in the Vosges. This re-discovery of the lost art of fish-breeding is understood to have been quite accidental on the part of Remy, although it is thought by some zealous Scotsmen that the Frenchman must have heard of the experiments of Mr. Shaw of Drumlanrig, who, for a few years previous to Remy's discovery, had been trying to solve some problems in the natural history of the salmon by means of the artificial system. The art had also been partially revived in Germany about the middle of last century by a gentleman of the name of Jacobi, who practised the artificial breeding of trout. Whether or not Remy had heard of either of these experimenters, it is certain that to him we owe the revival of the art in its larger or commercial sense; the others only used it as an adjunct to their study of the natural history of fishes.

It was the great waste of eggs incidental to the natural system of fish-breeding that led Remy, about 1842, in conjunction with Gehin, a coadjutor whom he assumed as a partner, to try what he could do in the way of re-peopling the fish-streams of his native district. His plan being at once successful, attracted the favorable notice of many of the French savans, and led to rewards and preferment for Remy; the new art was besides taken under the protection of the government. At Huningue, in Alsace, on the Rhine, a gigantic fish-nursery and egg-dépôt for the supply of eggs, and the dissemination of the art, was erected some years ago. Since the cession of Alsace to Germany, the operations of the establishment at Huningue (now known as Hünningen) have been conducted on a still larger scale by a German association.

The course of business at Huningue is as follows: The eggs are chiefly brought from the streams of Switzerland and Germany, and embrace those of the common trout, as well as the Rhine and Danube salmon, and the tender charr or ombre chevalier. People are appointed to capture gravid fish of these various kinds, and, having done so, to communicate the fact to Huningue. An expert is at once sent to deprive these fishes of their spawn, and bring it to the breeding or resting boxes, where it is carefully tended till it is ready to be despatched to some district in want of it. It is, of course, much more convenient to send the eggs than the young fish, as the former, nicely packed among wet moss in little boxes, can be carried to a distance with greater facility. The mode of artificially spawning a salmon is as follows. It should, of course, be ascertained that the spawn is in a perfectly matured state, and that being the case, the salmon is held under water in a large tub, while the hand is gently passed along its abdomen, when, if the ova be ripe, the eggs will flow out like so many pens. The eggs are then carefully washed, and the water is poured off. The male salmon is then handled in a similar way, when the contact of the milt immediately changes the eggs into a brilliant pink color. After being again washed, they may be ladled out into the breeding-boxes, and left to come to life in due season. The period occupied in hatching is different in different climates. At Stormontfield, where the eggs have no shelter, the usual period is about 135 days; but salmon ova have been known to burst in about half that period, and to yield very healthy fish. Great care is of course necessary in handling the ova. The eggs manipulated at Huningue are all carefully examined on their arrival, when the bad ones are thrown out, and those that are good are counted and entered in a record. The ova are watched with great care, and from day to day all that become addled are removed.

The applications for eggs, both from individuals and associations, are always a great deal more numerous than can be supplied; and before second applications can be entertained, it is necessary for the parties to give a detailed account of how their former efforts succeeded. It may be interesting to note, as regards the cost of pisciculture at Huningue, that the most expensive fish is the ombre chevalier. Of some species, as many as sixty or seventy per cent. of the eggs are lost. The general calculation, however, is twelve living fish for a penny.

The most sustained effort in British pisciculture has been in

connection with the salmon-fisheries of the river Tay. At Stormontfield, near Perth, a series of ponds has been constructed, and a range of breeding boxes laid down capable of receiving 500,000 eggs. The operations at Stormontfield were begun in 1853, and are still continued. It is calculated that by means of these ponds half a million of young salmon are annually added to the stock of the river Tay, the rental derived from which is now over £20,000 per annum. At several other places in Scotland, the artificial system is being introduced as an adjunct to the natural breeding resources of different rivers. The art of pisciculture was also introduced into Ireland, at the fisheries of Lough Mask

and thus it sometimes falls on an unpropitious growing-place. The spat of the oyster must have a 'coign of vantage' to which to cling; if it falls on a muddy bottom it is lost for ever. On the foreshores of the Ile de Ré, there are countless oyster-beds of the most simple description, in which the spat is reared and tended during its period of growth. All that is required for a good bottom to an oyster-bed is a rocky surface, which, if not found naturally, can be easily constructed by the laying down of stones and tiles.

Oyster-culture, in simple form, has been practised at Whitstable, on the coast of Kent, for a long period, and the famous

Reception-hall for Fish-eggs at Huningue.

and Carra, by the late Mr. Ashworth, who for a time obtained excellent practical results. These lochs contain an area of water equal to 35,000 acres; and a communication with the sea having been opened, they now teem with salmon. Several attempts have been made to introduce British fishes into the rivers of Australia, which in the case of trout, carp, tench, and perch, have been quite successful; but many thousands of salmon ova have been imported to Australia, New Zealand, and Tasmania, where a strong endeavor has been made to establish them in the rivers there. A salmon of 28 lbs. weight, caught in the Huon River, Tasmania, in the beginning of 1880, is proof that salmon are capable of acclimatization at the antipodes.

Pisciculture is largely practised in America, both by private persons and under the auspices of a commissioner, Mr. Spencer F. Baird, who acts on behalf of the government. Eggs are collected for distribution in the seas and rivers of the United States in enormous quantities, and are transported hither and thither to and from all parts of the country. As one example of what has been lately accomplished, it may be stated on the authority of a recent report to the House of Representatives, that the number of eggs of the Californian salmon collected during the season of 1875 at the United States Piscicultural Establishment on the Upper Sacramento, amounted to about 11,000,000, making a bulk of eighty bushels, and weighing with their packing gear nearly ten tons. In the years 1874 and 1875, a total of 26,137,855 eggs of shad and various kinds of salmon were distributed by the U. S. Fish Commission; and altogether 40,000,000 of fish eggs were handled in 1873-75. The Canadian government has established seven 'hatcheries,' in each of which about a million of ova are hatched.

Nearer home, namely in France, great efforts have been made to increase the supply of oysters by means of artificial cultivation. Oysters were cultivated in Italy during the classic ages, but the art of cultivating them seems to have been lost till it was accidentally re-discovered by an artisan of the Ile de Ré, who found out that the chief point in artificial oyster-culture is to insure a supply of spat. The seed of the oyster is too often carried away from the place of its birth by adverse winds acting on the waves,

'native' oysters are fed on ground at that place. Other experiments are in course of being made, and on some parts of the English coast, artificial *parcs* have been laid out on the French plan, in which plentiful supplies of oysters have been grown to maturity. The great difficulty in all experiments connected with oyster-culture is to find the requisite supply of spat from which to rear the mature animal.

Pisciculture is now being practised to some extent in several countries of Europe, and has been deemed of sufficient importance to demand the attention of governments. It is probable that the attention turned to the whole subject of pisciculture, and the example of the transportation of salmon to Australia, may lead to the introduction of valuable kinds of fishes into waters where they are now unknown. The grayling has thus already been introduced into the Clyde and Tweed. There is no apparent reason why every valuable fresh-water fish of Europe should not be plentiful in Britain.

PISCINA, the large basin (or *pond*) in the Roman *thermæ*, containing tepid water, in which the bather might swim.

PISCINA, a shallow stone basin with a drain (usually leading directly to the earth), in Roman Catholic churches, in which the priest washes his hands, and for rinsing the chalice at the celebration of the mass. In England, it is almost invariably placed on the south side of the choir, at a convenient height.

PISE, a kind of work used instead of brick, &c., for the walls of cottages. It consists of loam or earth hard rammed into framing, which, when dry, forms a wall.

PISEK (Boh. *Piseck*, sand), a small town of Bohemia, on the right bank of the Wottawa, an affluent of the Moldau, stands on

Piscina, Warmington.

a sandy plain (from which circumstance it probably received its name) 55 miles south-south-west of Prague. The town is old, and contains the remains of a royal castle. Among other institutions are a school of arts and a high school. The manufactures are woollen and cotton fabrics, iron wire, and musical instruments. Pop. (1880) 10,545.

PISHAMIN. See DATE PLUM.

PI'SOLITE (Gr. pea-stone), a concretionary limestone, differing from oolite in the particles being as large as peas.

PISTA'CIA, a genus of trees of the natural order *Anacardiaceæ*, having dioecious flowers without petals, and a dry drupe with a bony stone.—The **PISTACIA** or **PISTACHIO TREE** (*P. vera*) is a small tree of about 20 feet high, a native of Persia and Syria, but now cultivated in all parts of the south of Europe and North of Africa, and in many places naturalized. It has pinnate leaves, with about two pair of ovate leaflets and an odd one; flowers in racemes; fruit ovate, and about the size of an olive. The stone or nut splits into two valves when ripe; the kernel, which is of a bright green color, is very oleaginous, of a delicate flavor, and in its properties very much resembles the sweet almond. In the south of Europe and in the East, *Pistachio nuts* are much esteemed; but as they very readily become rancid, they are little exported to other countries. They are sometimes called *Green Almonds*. Oil is expressed from them for culinary and other uses. In cultivation, one male tree is allowed to five or six fertile ones. The tree produces flowers and even fruit readily enough in the south of England, but the summers are not warm enough to ripen the fruit, and the tree is apt to be destroyed by a severe frost.—The **MASTIC TREE**, or **LENTISK** (*P. lentiscus*), yields the gum-resin called Mastic (q. v.). It is a native of the countries around the Mediterranean.—The **TURPENTINE TREE** (*P. terebinthus*) yields the Turpentine (q. v.) known in commerce as *Cyprus Turpentine*, *Chian Turpentine*, or *Scio Turpentine*, which is of a consistency somewhat like that of honey, a greenish-yellow color, an agreeable odor, and a mild taste, and in its properties resembles the turpentine of the Coniferæ, but is free from acidity. It is obtained by making incisions in the trees, and placing stones for the turpentine to flow upon, from which it is scraped in the morning, before it is liquefied again by the heat of the sun. The tree is about 30 or 35 feet in height; and has pinnate leaves, of about three pair of leaflets and an odd one; the flowers in compound racemes, the fruit nearly globular. The kernel of the fruit is oleaginous and pleasant.

The **BATOU M TREE** (*P. Atlantica*), a round-headed tree of about 40 feet in height, a native of the north of Africa; produces a fruit much used by the Arabs; and a gum-resin of pleasant aromatic smell and agreeable taste, which exudes from its stem and branches, is chewed to clean the teeth and impart a pleasant smell to the breath.—The fragrant oil of the kernels of *P. oleosa*, a native of Cochinchina, is used by the people of that country to impart a perfume to ointments.

PISTIL, in Botany, the female organ of fructification in phanerogamous plants; that part of the Flower (q. v.) which, after flowering is over, is developed into the fruit. There is sometimes one pistil in a flower, sometimes more; in some flowers, which have numerous pistils, they form a number of whorls, one within another, sometimes on an elevated receptacle or elongated axis, or, more rarely, they are spirally arranged. In every case, the center of the flower is occupied by the pistil or pistils, if present. See FLOWER. A pistil is either formed of a single Carpel (q. v.), as is the case when there are numerous pistils, or of several carpels combined; and the number of carpels of which the pistil is formed is often indicated by the number of the cells of the germen, or by its lobes or angles. The pistil usually consists of a Germen (q. v.) or ovary, in which the Ovules (q. v.) are contained, and which is surmounted by a stigma, either immediately or through the intervention of a style; but in Gymnogens (q. v.), there is neither germen, style, nor stigma, the female organs of fructification being mere naked ovules. The germen is always the lowest part of the pistil. The stigma exhibits an endless variety of forms, and is adapted to the reception and retention of the pollen grains requisite for fecundation, partly by the roughness of its surface—which is of a somewhat lax cellular tissue, covered with projecting cells, often in the form of minute warts, and often elongated into hairs—and partly by the secretion of a viscous fluid.

The stigma when not sessile—or seated immediately on the germen—is supported by the style, which rises from the germen, and on the top of which the stigma is generally placed. The style is sometimes very long and slender, sometimes very short; the germen sometimes passes imperceptibly into the style, and sometimes the style rises from it abruptly; and similar differences appear in the relations of the style and stigma; the stigma, however, may be regarded as always an expansion of the top of the style, although it is sometimes, but rarely, situated on one or both sides of the style, beneath its summit. In like manner, by peculiar

modifications taking place in the growth of the germen, the style sometimes seems to arise from beneath its apex, or even from its base; but it always rises from what is, structurally considered, the real apex of the germen. When several carpels are united to form one germen, they are sometimes again separated in their

Pistils :

- 1, Section of flower of a species of Primrose, showing the pistil laid open; numerous ovules attached to a free central placenta. 2, Section of flower of Camellia, with corolla removed, showing two of the four ovules, and the style. 3, Pistil of the Barberry, consisting of several carpels combined; the style very short and thick, the stigma shield-like. 4, Section of the ovary of a Lily. 5, Section of flower of Cherry, showing pistil of two separate carpels, only one of which comes to perfection in fruit. 6, Pistil of Pea, opened; a, ovule; b, placenta; c, umbilical cord.—From Balfour's *Class-Book of Botany*.

styles, and more frequently in their stigmas, so that one germen bears several styles, or the style divides at some point above the germen, or one style is crowned by a number of stigmas. The style is usually cylindrical; and when this is not the case, it is often owing to the combination of several styles into one, although sometimes the style is flat and even petal-like. It is traversed throughout its whole length by a canal, which, however, is in general partly filled up by cells projecting from its sides, and often also by very slender tubes extending in the direction of its length; the function of the canal, to which in some way or other the enclosed slender tubes are subservient, being to bring about the connection between the pollen and the ovules for fecundation (q. v.).

The length of the style is adapted to the ready fecundation of the ovules, being such that the pollen may most easily reach the stigma; and in erect flowers, the styles are usually shorter than the stamens; in drooping flowers, they are longer than the stamens. After flowering is over, when fecundation has taken place, the foramen of the ovules closes, the germen enlarges and ripens into the fruit, whilst each ovule is developed into a seed. The style and stigma meanwhile either fall off, or remain and dry up, or they increase in size, and are changed into various kinds of appendages of the fruit, as feathery awns, beaks, &c.

PISTILLIDIUM, in Botany, a term which, along with *Antheridium* (q. v.), must be regarded as provisional, and as expressive of an opinion, probable, but not yet ascertained to be true. The evidence in favor of it, however, seems continually to increase, and its great probability is more and more generally acknowledged. The pistillidium is an organ of cryptogamous plants, supposed to perform functions in fructification analogous to those of the pistil in phanerogamous plants. It consists of a germen-like body—the *sporangium*, *theca*, or *spore-case*—hollow, and containing Spores (q. v.), by which the species is propagated. These spore-cases are very various in their forms and in the situations which they occupy in different orders and genera; being sometimes immersed in the substance of the plant, sometimes distinct from it, sometimes sessile, sometimes stalked, &c. See the articles on the different cryptogamous orders.

PISTO'JA (anc. *Pistorium*), a manufacturing town of Italy, in the province of Florence, and 21 miles by railway north-west of the city of that name, stands on a gentle rising ground at the foot of the Apennines. It is well built; its streets are thoroughly Tuscan, and it is surrounded by lofty and well-preserved walls. The chief buildings are the cathedral, built at various times, and containing a number of good pictures; several old and interesting palaces, and a number of churches, some of which are of importance in the history of medieval architecture and sculpture. The principal manufactures are iron and steel wares, and paper. Pop. (1872) 12,966.

PISTOL is the smallest description of fire-arm, and is intended to be used with one hand only. Pistols vary in size from the delicate saloon-pistol, often not six inches long, to the horse-pistol,

Ancient Pistols :

1, Long Wheel-lock Pistol ; 2, Pocket 'Wheel-lock Dag'—temp. Elizabeth.—From Fairholt's *Costume in England*.

which may measure 18 inches, and sometimes even two feet. They are carried in holsters at the saddle-bow, in the belt, or in the pocket. Every cavalry soldier should have pistols, for a fire-

Modern Pistol.

arm is often of great service for personal defence, and almost indispensable in giving an alarm or signal. Sailors, when boarding an enemy's ship, carry each two in their waistbelts.

As early as the reign of Henry VIII., the English cavalry carried clumsy pistols called 'dags.' The latest improvement on the pistol is the Revolver (q. v.)

PISTOLE, the name formerly given to certain gold coins current in Spain, Italy, and several parts of Germany. The pistole was first used in Spain, and was originally equivalent to about 11 old French livres, but till 1728 it was merely an irregular piece of gold. From this time till 1772, its value was 17s. 1d. sterling; but it was after this date decreased till it reached the value of 80 reals, or 16s. 2d. sterling. The Italian pistoles were also gold coins, and varied considerably in value: that of Rome = 13s. 9d.; of Venice = 16s. 2½d.; of Florence and Parma = 16s. 10½d.; and the old coin of Piedmont = £1, 2s. 7½d., or 24 old liras. Gold coins of this name used to be current in Hesse-Cassel, Switzerland, Brunswick, and Hamburg, but were in most cases merely convenient multiples of the ordinary thaler and guilder. Of late years, and especially since the introduction of new systems of coinage in Spain and Italy, and of a uniform system in the German Empire, the name P. is scarcely ever used.

PISUM. See PEA.

PIT, in Gardening, is an excavation in the ground, intended to be covered by a Frame (q. v.), and to afford protection to tender plants in winter, or for the forcing of vegetables, fruits, &c. Pits are often walled on all sides, although in many cottage gardens, excellent use is made of pits which are mere excavations. The walls are often raised above the ground, particularly the back wall, the more readily to give slope to the glazed frame. A pit in which no artificial heat is supplied, is called a *cold pit*; but when forcing is intended, flued pits are often used. Artificial heat is sometimes also given by means of fermenting matter. The ventilation of pits, as much as the weather will permit, is of the greatest importance.

PITTA-HEMP, one of the names of the Agave or Aloe fibre. See AGAVE.

PIT'AKA (literally, 'basket') is, with the Buddhists, a term denoting a division of their sacred literature, and occurs especially in combination with *tri*, 'three;' *tripit'aka* meaning the three great divisions of their canonical works, the *Vinaya* (discipline), *Abhidharma* (metaphysics), and *Sûtra* (aphorisms in prose), and collectively, therefore, the whole Buddhistic code. The term 'basket' was applied to these divisions, because the palm-leaves on which these works were written were kept in baskets, which thus became a part of the professional utensils of a Bhikshu, or religious mendicant.

PITCAIRN ISLAND, a solitary island in the Pacific Ocean, lying at the south-eastern corner of the great Polynesian Archipelago, in lat. 25° 3' S., and long. 130° 6' W. Its length (24 miles) is about twice its breadth, and the total content is approximately 1½ square miles; so that, except from its being the only station (with the exception of the Gambier Islands) between the South American coast and Otaheite at which fresh water can be procured, it would be too insignificant to deserve notice, were it not for the manner in which it was colonized. The island is wholly surrounded by rocks; it has no harbor, and its soil is not

very fertile. It was occupied in 1790 by the mutineers of the *Bounty* (see BLYTH, WILLIAM), who, after touching at Tootobouai, sailed for Tahiti, where they remained for some time. Christian, the leader of the mutineers, however, fearing pursuit, hastened their departure; and after leaving a number of their comrades who preferred to stay on the island, they brought off with them 18 natives, and sailed eastward, reaching P. I., where they took up their residence, and burned the *Bounty*. They numbered then 9 British sailors—for 16 of the sailors had preferred to remain at Tahiti, and of these, 14 were subsequently captured, and (September 1792) three of them executed—and 6 Tahitian men, with 12 women. It was impossible for concord to subsist in a band of such desperate character; and, in the course of the next ten years, all the Tahitian men, all the sailors, with the exception of Alexander Smith (who subsequently changed his name to John Adams), and several of the women, had died by violence or disease. From the time of their leaving Tahiti, nothing had been heard of them, and their fate was only known when an American, Captain Folger, touched at P. I. in 1808, and on his return, reported his discovery to the British government; but no steps appear to have been taken by the latter.

On September 17, 1814, a British vessel, the *Britain*, called at the island, and found old Adams still alive, commanding the respect and admiration of the whole little colony, by his exemplary conduct and fatherly care of them. Solitude had wrought a powerful change in Adams; and his endeavors to instil into the young minds of his old companions' descendants a correct sense of religion, had been crowned with complete success, for a more virtuous, amiable, and religious community than these islanders, had never been seen. They were visited by British vessels in 1825 and 1830, and the reports transmitted concerning them were fully corroborative of the previous accounts; but, in 1831, their numbers (37) had become too great for the island, and at their own request, they were transported to Tahiti, in the *Lucy Ann*, by the British government. But, disgusted at the immorality of their Tahitian friends and relatives, they chartered a vessel, defraying the cost of it in great part with the copper bolts of the *Bounty*, and most of them returned to P. I. at the end of nine months. In 1839, being visited by Captain Elliot of H.M.S. *Fly*, they besought to be taken under the protection of Britain, on account of the annoyances to which they had been subjected by the lawless crews of some whale-ships which had called at the island; and, accordingly, Captain Elliot took possession of it in the name of Her Majesty, gave them a Union Jack, and recognized their self-elected magistrate as the responsible governor. He also drew up for them a code of laws, some of which are amusing from the subjects of which they treat, but the code was of great use to the simple islanders. From this time, they were frequently visited by European ships; and, in 1855, finding their numbers again too great for the island, they petitioned government to grant them the much more productive Norfolk Island, to which they were accordingly removed in 1856.

In 1859, however, two families, numbering in all 17, returned to P. I., reducing the number on Norfolk Island to 202, and others have since followed. From their frequent intercourse with Europeans, the Pitcairn Islanders have, while still retaining their virtuous simplicity of character and cheerful hospitable disposition, acquired the manners and polish of civilized life, with its education and taste. They are passionately fond of music and dancing, the latter evidently a legacy from their maternal ancestry. The men are engaged in whaling and herding cattle, or in cultivating their gardens and plantations; while the women (who seem to be the more industrious class) attend to their families, manage the dairies, and take an occasional part in field-labor.

P. I. was first discovered by Carteret in 1767, and was named by him after one of his officers; but it was never visited by Europeans till taken possession of by the mutineers. When Admiral de Horsey visited P. I. in 1777, there were in all 16 men, 19 women, 25 boys, and 30 girls on the island. The total population, in 1881, was 96.

PITCH. The common kind of pitch is the black residue which remains after distilling wood-tar. See TAR. It is made extensively in Russia, Norway, and North America. It is a most useful material for protecting wood from the action of water, hence it is used for calking the seams, and coating the outsides of ships and boats; it is also applied to the inside of water-casks, and many similar uses. A variety of pitch is now obtained from the distillation of coal-tar, and another from bone-tar; the latter is said to be nearly equal in value to that from wood, but coal-pitch wants the toughness which is one of the more valuable qualities of wood-pitch. It is, however, much used in making artificial asphalt for building and paving purposes; and for the black varnish used for coating iron-work to keep it from rusting. Pitch is solid at the ordinary temperature of our climate, but softens and melts with a small accession of heat.

PITCH, BURGUNDY. See BURGUNDY PITCH.

PITCH, the degree of acuteness of musical sounds. A musical sound is produced by a series of vibrations recurring on the ear at precisely equal intervals; the greater the number of vibrations in a given time, the more acute or higher is the pitch. In stringed instruments, the pitch is dependent on the length, the thickness, and the degree of tension of the strings; the shorter and thinner a string is, and the greater its tension, the higher is the pitch of the note. In wind instruments, where the notes are produced by the vibration of a column of air, as in the mouth-pipes of an organ, the pitch is dependent on the length of the column set in motion; the shorter the column of air, the higher the pitch becomes.

The pitch of musical instruments is adjusted by means of a tuning fork, consisting of two prongs springing out of a handle, so adjusted as to length that, when struck, a particular note is produced,

that note being C

in Britain, and A

in

Germany. It is obviously important to have a recognized standard of pitch, by which instruments and voices are to be regulated, but there is, unfortunately, not the uniformity that might be desired in the pitch in actual use. For a long time prior to 1859, concert pitch had been gradually rising, to the detriment of the voices of public singers. The C tuning-fork, in use in 1699, made 489 vibrations per second, while in 1859, the number of vibrations had increased to 538. Mr. Hullah, in 1842, in the numerous classes instituted by him under the sanction of the Committee of Council on Education, found it necessary to secure a uniform standard of pitch, and adopted 512, which has an especial convenience as being a power of 2. The French Imperial government, in 1858, fixed on 522. In 1859, a Committee of the Society of arts was appointed to consider the subject of a uniform musical pitch. Their deliberations lasted twelve months. Sir John Herschel, in a letter to the Committee, strongly recommended the number 512. It was agreed on all hands that the then existing opera-pitch of 546 was too high and painful to the singers of soprano music. The instrumental performers stated that they could lower the pitch to 528, but if they had to lower it to 512, some of them would have to purchase new instruments; and, in consequence apparently of their representation, the Committee reported in favor of 528.

PITCHBLEND, a mineral which is essentially oxide of Uranium (q. v.), with slight mixtures of other substances. Its color is grayish-black or brownish-black. It is infusible before the blowpipe, but the addition of borax, with which it fuses into a dull yellow glass.

PITCHER PLANT. See **NEPENTHES**.

PITCHSTONE, a name sometimes given to a variety of common Opal (q. v.), brown, black, gray, red, or of mixed colors; the lustre more resinous than in opal, and the fracture less perfectly conchoidal. It occurs in several localities in the British Islands, in Saxony, &c.—The same name is given to another mineral (Ger. *Pechstein*), a variety of Felspar (q. v.), occurring as a rock in dikes which traverse strata or in overlying masses, compact, slaty, or in concentric slaty, concretions. It exhibits great variety of color, and has a somewhat resinous appearance. It often contains numerous imbedded crystals of felspar, and is then called *P. porphyry*.

PITCHURIM BEANS, or **SASSAFRAS NUTS**, an occasional article of importation from South America, are the seed-lobes of *Nectandra Puchury*, a tree of the same genus with the Greenheart (q. v.), growing on the banks of the Rio Negro and elsewhere in the rich alluvial parts of the basin of the Amazon. They are about an inch and a half long, and half an inch broad. They are much in request among chocolate manufacturers for flavoring chocolate, as a substitute for vanilla. They are sometimes called Wild Nutmegs, because of a resemblance to nutmeg in flavor. The name Sassafras Nuts is also due to the flavor, which approaches that of Sassafras bark; and the tree belongs to the same natural order with the Sassafras tree.

PITH (*Medulla*), the light cellular substance which occupies the center of the stem and branches in Exogenous Plants (q. v.). In the earliest stage of a young stem or branch, it is entirely composed of pith and bark, by which alone, therefore, young buds are nourished; the vascular bundles or woody fibre appearing afterwards, and in trees and shrubs, generally increasing, so as to constitute the greater part of the substance of the stem and branches, whilst the pith is ultimately reduced to a very small column in the center. The pith, however, exists even in the most mature woody stem, and maintains its connection with the bark by means of *Medullary Rays*, analogous in their character to the pith itself, and which exists even in the most compact wood, although much compressed by the woody layers, and in a transverse section appearing as mere lines. The medullary rays con-

vey to the central parts of the stem the secretions of the bark necessary for their nourishment. P. is in general entirely composed of cellular tissue; vessels occurring in it only in a few plants. Its cells diminish in size from the center towards the circumference. In a few plants, it exhibits cavities which have a regular arrangement; in many herbaceous plants of rank growth, large irregular cavities occur in it. The pith is immediately surrounded by a thin vascular layer called the *Medullary Sheath*, consisting chiefly of spiral vessels, which continue to exercise their functions during the life of the plant.

PITHE'CIA. See **SAKI**.

PITHE'CUS. See **ORANG**.

PIT'TON BARK. See **CARIBBEE BARK**.

PIT'R'I (a Sanscrit word literally meaning father = Latin *pater*, in the plural *Pitayas*, but in English translations from the Sanscrit usually Anglicized to *Pitr'is*), a name which, in a general sense, means the deceased ancestors of a man, but in the special sense in which it occurs in Hindu mythology, denotes an order of divine beings inhabiting celestial regions of their own, and receiving into their society the spirits of those mortals for whom the funeral rites (see **S'RADDHA**) have been duly performed. They include, therefore, collectively the manes of the deceased ancestors; but the principal members of this order are beings of a different nature and origin. According to Manu, they were the sons of Marichi, Atri, Angiras, and the other R'shis or saints produced by Manu, the son of Brahmā; and from them issued the gods, demons, and men. According to several Purānas (q. v.), however, the first Pitr'is were the sons of the gods; and to reconcile this discrepancy, a legend relates that the gods having offended Brahmā by neglecting to worship him, were cursed by him to become fools; but upon their repentance, he directed them to apply to their sons for instruction. Being taught accordingly the rites of expiation and penance by their sons, they addressed the latter as fathers, whence the sons of the gods were the first Pitr'is (fathers). See Wilson's *Vishn'u-Purāṇa*. Manu enumerates various classes of Pitr'is in defining those who were the ancestors of the gods, those who were the ancestors of the demons, and those from whom proceeded the four castes severally; but he adds, at the same time, that these are merely the principal classes, as their sons and grandsons indefinitely must likewise be considered as Pitr'is. The Purāṇas divide them generally into seven classes, three of which are without form, or composed of intellectual, not elementary substance, and assuming what forms they please, while the four other classes are corporeal. In the enumeration, however, of these classes the Purāṇas differ. The Pitr'is reside in a world of their own, called Pitr'i-loka, which is sometimes supposed to be the moon; according to the Purāṇas, it is below the paradise of Indra, and is also the abode of the souls of devout Brahmans.

The time at which the Pitr'is are to be worshiped, the libations which they are to receive, the benefits which they derive from them, and the boons which they confer on the worshiper, are all minutely described in the Purāṇas. See **S'RADDHA**. A song of the Pitr'is, as given by the *Vishn'u-Purāṇa*, may convey an idea of the importance attributed to this worship, and of the manner in which the Brahmans turned it to their profit. It runs as follows: 'That enlightened individual who begrudges not his wealth, but presents us with cakes, shall be born in a distinguished family. Prosperous and affluent shall that man ever be who, in honor of us, gives to the Brahmans, if he is wealthy, jewels, clothes, lands, conveyances, wealth, or any valuable presents; or who, with faith and humility, entertains them with food, according to his means, at proper seasons. If he cannot afford to give them dressed food, he must, in proportion to his ability, present them with unboiled grain, or such gifts, however trifling as he can bestow. Should he be utterly unable even to do this, he must give to some eminent Brahman, bowing at the same time before him, sesamum seeds, adhering to the tips of his fingers, and sprinkle water to us, from the palms of his hands, upon the ground; or he must gather, as he may, fodder for a day, and give it to a cow; by which he will, if firm in faith, yield us satisfaction. If nothing of this kind is practicable, he must go to a forest, and lift up his arms to the sun and other regents of the spheres, and say aloud: "I have no money, nor property, nor grain, nor any thing whatever fit for an ancestral offering; bowing therefore to my ancestors, I hope the progenitors will be satisfied with these arms tossed up in the air in devotion." See Wilson's *Vishn'u-Purāṇa*.

PITT, WILLIAM, the second son of the Earl of Chatham and of Lady Hester Grenville, daughter of the Countess Temple, was born on the 28th May 1759. His genius and ambition displayed themselves with an almost unexampled precocity. 'The fineness of William's mind,' his mother writes of him when he was but twelve years old, 'makes him enjoy with the greatest pleasure what would be above the reach of any other creature of his small

age.' Owing to the excessive delicacy of his constitution, it was found impossible to educate him at a public school. His studies were, however, prosecuted at home with vigor and success. In 1773, he was sent to the university of Cambridge, where his knowledge of the classics seems to have astonished veteran critics. To modern literature he appears to have been utterly indifferent—he knew no continental language except French, and that very imperfectly. Among English poets, he liked Milton best; the debate in Pandemonium being his favorite passage. In 1780, P. was called to the bar. He took chambers in Lincoln's Inn, and joined the western circuit. A general election having taken place in the autumn of the same year, he stood for the university of Cambridge; but he was at the bottom of the poll. Through the influence, however, of the Duke of Rutland, he obtained a seat in parliament as member for Appleby. Lord North was now prime minister. The opposition consisted of two parties; one being led by Rockingham and Fox, the other by Lord Shelburne. The latter consisted chiefly of the old followers of Chatham; and to this party Pitt naturally became attached. On 26th February 1781, he made his first speech in parliament. It was in favor of Burke's plan of economical reform, and was a splendid success. 'It is not a chip of the old block,' said Burke; 'it is the old block himself.' Shortly before the meeting of parliament, in the autumn of 1781, the news arrived of the surrender of Cornwallis and his army.

In the debate on the address, P. spoke with even more energy and brilliancy than on any former occasion. No one was so loud in eulogy as Henry Dundas, Lord Advocate for Scotland; and from this night dates a connection between him and P., which was only broken by death. After several defeats, the ministry resigned, and Rockingham was called on to construct a cabinet. P. was offered the vice-treasurership of Ireland; but he declined to accept a position which did not confer a seat in the cabinet. On 7th May 1782, he made his first motion for a reform in the representation of the people; which motion was lost by only 20 votes in a house of more than 300 members. The reformers never again had so good a division till 1831. At the end of three months after his accession to office, Rockingham died; Lord Shelburne succeeded to the head of the treasury; and P., at the age of 23, became Chancellor of the Exchequer. In opposition to the government, there was then formed a coalition emphatically known as 'The Coalition.' On Lord Shelburne's resignation in 1783, the king himself, who hated the Coalition, tried to persuade P. to take the helm of affairs; but he resolutely declined. The Duke of Portland succeeded, with Fox and North as Secretaries of State. P., from the Opposition benches, brought for a second time the question of parliamentary reform before the House. His motion was lost by 298 votes to 149. On the prorogation, he visited the continent for the first and last time. In 1783, the ministry having been defeated on a motion for transferring the government of India to parliament, P. became First Lord of the Treasury and Chancellor of the Exchequer. But parliament was dead against him; between 17th December 1783 and 8th March 1784, he was beaten in sixteen divisions. The nation, however, was in his favor; both on account of his policy, and from admiration of his private character. Pecuniary disinterestedness is what all can comprehend; and even when known to be overwhelmed with debt, when millions were passing through his hands, when the greatest men in the land were soliciting him for honors, no one ever dared to accuse him of touching unlawful gain.

At the general election in 1784, 160 supporters of the Coalition lost their seats, P. himself heading the poll for the university of Cambridge. He was now, at 25 years old, the most powerful subject that England had seen for many generations. He ruled absolutely over the cabinet, and was at once the favorite of the sovereign, of the parliament, and of the nation; and from this date, the life of P. becomes the history of England and of the world. For seventeen eventful years, he held his great position without a break. In 1784, he established a new constitution for the East India Company. In 1786, he carried through a commercial treaty with France on liberal principles. In the same year, he established a new sinking fund; a scheme which experience has shown to be wrong in principle, though it was long viewed with favor by the nation. To exertions which were now begun for the abolition of the slave-trade, he gave the help of his eloquence and power. In 1788—1789, he maintained against Fox the right of parliament to supply the temporary defect of royal authority occasioned by the incapacity of the king. The year 1793 saw the beginning of the great war with France. Authorities differ as to the cause. It is, however, certain that P.'s military administration was eminently unsuccessful. But no disaster could daunt his spirit. When a new French victory, a rebellion in Ireland, a mutiny in the fleet, and a panic in the city had spread dismay through the nation, P. from his place in parliament poured forth the language of inextinguishable hope and inflexible resolution. Disaster abroad was regularly followed by triumph at home, until at last he had no longer an opposition to encounter. In 1799, he effected the union with Ireland. It was part of his scheme to

relieve the Roman Catholic laity from civil disabilities, and to grant a public maintenance to their clergy; but the obstinacy of the king frustrated this design. Chagrined by this failure P. resigned office in 1801. He was succeeded by Mr. Addington, to whom for a while he gave his support.

In 1804, he returned again to the head of the treasury, which position he continued to hold till his death on 23d January 1806. This event was doubtless hastened by the stupendous success of Napoleon. The peculiar look which he wore during the last days of his life was pathetically termed by Wilberforce 'the Austerlitz look.' The impeachment also of his friend, Lord Melville, is supposed greatly to have hastened his end. It gave him, he said in parliament, a deep pang. His voice quivered as he uttered the word; and it seemed as if the man of iron were about to shed tears. 'He was,' says Macaulay, 'a minister of great talents, honest intentions, and liberal opinions, . . . but unequal to surprising and terrible emergencies, and liable in such emergencies to err grievously, both on the side of weakness and on the side of violence.' But what man ever lived, we may ask, who, placed in such circumstances as P., would not often have greatly erred? His policy was liberal beyond his age, at least he wished it to be so, although he was often obliged to yield to the prejudices of his sovereign. He resigned office because he could not carry Catholic emancipation. He laid before the king unanswerable reasons for abolishing the Test Act. He was more deeply imbued with the doctrines of free-trade than either Fox or Grey. It cannot indeed be denied that he was addicted to port-wine, and that he died overwhelmed with debts; parliament voting £40,000 to his creditors. High as his character stands, it would have stood even higher had he united the virtue of frugality to that of disinterestedness. See *Life of Pitt* by Lord Stanhope (Lond. 1861); also Lord Macaulay's *Biographies* (Edin. 1860). In the former work, vol. ii., p. 185, will be found a valuable criticism on Macaulay's memoir.

PI' TTACUS, one of the 'Seven Wise Men' of ancient Greece, was born at Mitylene, in the island of Lesbos, about the middle of the 7th c. B.C. The incidents of his life do not perhaps rest on a very secure historical basis, but he is by no means to be regarded as a merely traditionary personage. We may feel quite certain that his career and character were substantially what later history represents them. About 612 B.C., in conjunction with the brothers of Alcæus the poet, he overthrew the 'tyrant' Melanchrus, and put him to death. He next figures in the contest between the Lesbians and the Athenians for the possession of Sigeum in the Troad, and displayed as much valor on the battle-field as Alcæus did cowardice. His townsmen, the Mitylenæans, were so pleased with his deeds of prowess, that they gave him a portion of the city-territory, which he dedicated to sacred uses, and which was known long after as the 'Pittacian land.' Meanwhile, the civic struggles did not cease; the democratic party, however, roughly represented by a series of popular 'tyrants,' were in the ascendant, and the oligarchic aristocrats, at the head of whom was Alcæus, were finally banished. P. was subsequently chosen dictator, 589 B.C., to prevent the turbulent exiles from returning to Mitylene, and ruled absolutely with great success for ten years, after which he voluntarily resigned his power, and withdrew into honored retirement. He died in 569 B.C. Many of the anecdotes preserved by tradition concerning P. are probably apocryphal; but they all attribute to him the same characteristics—great moral sagacity, a contempt of outward pomp, and a plain practical understanding. His favorite maxim, *Gnothi Kaïrón* ('Know the fitting moment'), may be recommended to all statesman and politicians. To P. is also ascribed the saying which has so often been verified in actual history, *Chalepòn, esthìon emmenai* ('It is a misfortune to be eminent'). Of his 600 didactic verses, only four are extant, and these prove that he was strongly impressed with the falsehood and insincerity of men. See Schneidewin's *Delectus Poësis Græcorum Elegiacæ, &c.* (Grot. 1839).

PITOSPORA' CEE, a natural order of exogenous plants, allied to *Vitaceæ* (the Vine, &c.), and containing nearly 100 known species of trees and shrubs, chiefly Australian, although a few are natives of different parts of Asia, Africa, and the islands of the Pacific. To this order belongs the genus *Billardiera* (q. v.). The genus *Sollya* also deserves notice, as containing some of our most beautiful green-house climbers.

PI' TTSBURGH, a city of Pennsylvania, U.S. of America, at the confluence of the Alleghany and Monongahela rivers, at the head of the Ohio, lat. 40° 26' 34" N., long. 80° 2' 38" W. It is situated among some of the richest deposits of bituminous coal and iron in America, supplying, in 1864, coal to the amount of 135,215,250 bushels. The city possesses 60 iron-foundries, 42 iron and steel works, nearly 600 furnaces, extensive machine-shops, and manufactures of steam-boilers, engines, nails, &c. The annual value of the iron manufactures is about 80,000,000 dollars. There are also copper-smelting and rolling mills, 6 cotton-mills, oil-refining works, white-lead and glass works. The

numerous foundries and factories fill the atmosphere with smoke, and have given P. the name of the Birmingham of America. It is connected by steamboats with the whole Mississippi Valley, and by railways and canals with Philadelphia and Cleveland. Among its public buildings are a fine court-house, the largest Roman Catholic cathedral in the country, 141 churches, railway, aqueduct, and other bridges, United States arsenal, schools and colleges, western state penitentiary, &c. Nine railways center at this bustling city. It occupies the site of Fort Pitt, and the older French Fort Duquesne, in an expedition against which, the British general, Braddock, was defeated in 1755, by an allied force of French and Indians. It was taken, on a third attempt, by General Forbes in 1758. The city was chartered in 1816; in 1845, it was nearly destroyed by fire. Pop. (1840) 21,115; (1860) 49,220; (1870) 86,076. The annexation of adjacent boroughs and townships raised the pop. to 156,381 in 1880.

PITTSFIELD, a city in Massachusetts, U.S. of America, on the Boston and Albany Railway, 151 m. W. of Boston, and the terminus of the Housatonic and the Pittsfield and North Adams Railways. It has manufactures of cotton and woollen goods, &c.; a medical college, 9 churches, &c. Pop. (1880) 13,367.

PITUITARY BODY, a small reddish-gray mass of an oval form, weighing from six to ten grains, and situated on the sella turcica of the sphenoid bone, on the floor of the cavity of the skull. It is very vascular, and in its structure it resembles the ductless glands. In the fetus, it is relatively larger than in the adult, and contains a cavity which subsequently disappears. It derives its name from its having been formerly supposed to secrete the fluid which (as we now know) is yielded by the Schneiderian or pituitary membrane of the nostrils. Its function is not known.

PITYRIASIS (from the Greek word *pityron*, bran) is the term given to one of the squamous or scaly diseases of the skin, in which there is a continual throwing off of bran-like scales of epidermis, which are renewed as fast as they are lost. It may occur upon any part of the body, giving rise to brown patches, in which there are sensations of itching, tingling, or pricking. It is more easily cured than the other scaly diseases, and its removal can generally be effected by the frequent use of the warm bath; or, if it fails, recourse may be had to alkaline or sulphur baths; due attention being at the same time paid to the general health. It sometimes occurs on the scalp, when it is known as *dandruff*, and must be treated with weak alkaline lotions, or, if these fail, with tar ointment, provided there is no inflammation. There is a variety known as *Pityriasis versicolor*, which is probably due to the presence of a parasitic fungus, the *Microsporon furfurans*; but whether the fungus is the positive cause of the disease, or only an attendant on it, finding a suitable *nidus* in the diseased epidermis is not certain. This variety may be detected by a microscopic examination of the exfoliated scales, when the spores and filaments of the fungus will be detected. The treatment of this affection must be solely local. Dr. Watson mentions a case which yielded at once to a couple of sulphur baths. Probably the best remedy is the application of a saturated watery solution of sulphurous acid gas, or of one of the sulphites dissolved in diluted vinegar.

PIU (in Ital. more), as a musical term, when prefixed to another word, intensifies its meaning—e. g., *più mosso*, with more movement.

PIUS, the name of nine among the Roman pontiffs, of whom the following only appear to call for particular notice.—PIUS II., originally known as Æneas Sylvius, was a member of the noble family of Piccolomini, and was born (1405) at Corsignano, in the duchy of Siena. His early life was not free from serious irregularities, but he made amends by his subsequent decorous conduct; and his eminent abilities as a canonist led to his being employed, when but 26 years of age, as secretary of the Cardinal of Fermo, in a post of the highest confidence at the council of Basel (q. v.). He was intrusted by that council—the views of which, in its conflict with the pope, he fully shared—in several commissions of great importance; and on the election of the antipope, Felix V., Æneas Sylvius was chosen as his secretary. But having been sent by him as ambassador to the Emperor Frederick III., he was induced to accept office in the imperial court, and served on several embassies and other missions of importance on behalf of the emperor. In the difficulties between Frederick and the Pope Eugenius IV., which arose after the council of Florence, Æneas conducted so skillfully a negotiation with which he was intrusted, that the pope was induced to retain him in his own court, in the capacity of secretary. His views of church matters having undergone a considerable change, he continued in equal favor under the successor of Eugenius, Nicholas V., 1447; and under Callistus III., he was elevated to the cardinalate. On the death of Callistus in 1458, he was elected pope, and took the name of Pius II. His pontificate was embarrassed by some contests on German affairs, but it is chiefly rendered memorable by the sustained efforts which

P.—the first in this policy of a long line of pontiffs, to whom the public security of Europe owes a deep obligation—made to organize an armed confederation of Christian princes to resist the progress of the Turkish arms.

This organization, however, for a long time did not lead to any considerable results. P. died, August 14, 1464. The literary reputation of the scholar, Æneas Sylvius, has partially eclipsed the historical fame of the Pope Pius. He was one of the most eminent scholars of his age. His works were published at Basel (1 vol. fol., 1551), but many of his works are not included in that edition. They consist chiefly of histories, or historical dissertations and materials of history; but the most interesting portion of his collected works are his letters, which are very numerous, and full of details, characteristic as well of the writer as of the age. The same may be said of a biographical commentary, which is in truth an autobiography, being chiefly written from his own dictation, by his secretary, John Gobelinus, published at Frankfurt in 1614. See Voigt's *Life of Pius* (Berl. 1856).—PIUS IV., Giovanni Angelo Medici, uncle of Saint Carlo Borromeo, deserves to be noticed from his connection with the celebrated creed known under his name. He was elected in 1560; and his pontificate is chiefly memorable as that in which the protracted deliberations of the council of Trent (q. v.) were brought to a close. P. had the duty, in December 1563, of issuing the bull confirmatory of its decrees. The well-known creed called the Creed of Pius IV., and sometimes the Tridentine Creed, was issued by P. IV. as an embodiment of all the doctrines defined in that council. P. died, December 8, 1565, in the arms of his nephew, Carlo Borromeo.—PIUS V., a saint of the Roman Catholic Church, originally named Michele Ghisleri, was born of poor parents, in the village of Bosco, near Alessandria, in 1504, and at the age of fourteen, entered the Dominican order. His eminent merits were recognized by Paul IV., who named him Bishop of Satrì, in 1556, and cardinal in the following year. Of austere and mortified habits, he carried into his administration the same rigor which distinguished his personal conduct; and when appointed inquisitor-general for Lombardy, he employed the most rigorous measures in repressing the progress of the Reformation, which had begun to effect an entrance. He was afterwards translated to the see of Mondovì; and immediately after the death of Pius IV., he was chosen unanimously as his successor, January 8, 1566.

P. carried into his pontifical life the same personal austerity and administrative rigor which he had evinced as a bishop. Applying to others the same rules which he enforced upon himself, he enacted a number of severe laws for the regulation of public morals, prohibiting bull-fights, suppressing prostitution, and proscribing a variety of popular but demoralizing exhibitions. The Roman Inquisition, too, under his government, exercised a severity of which no other pontificate has shown any example. He endeavored to enforce everywhere the disciplinary decrees of the Council of Trent; and the whole spirit of his pontificate is most strikingly exhibited in the decree by which he ordered the yearly publication of the celebrated bull, *In Cana Domini* (q. v.). It was an application to the 16th c. of the principles and the legislation of the Hildebrandine epoch. But the most momentous event of the pontificate of P. was the expedition which he organized, with Spain and Venice, against the Turks, and which resulted in the great naval engagement of the Gulf of Lepanto, on 7th October 1571. P. died in the following May, 1572. He was canonized by Clement XI. in 1712.—PIUS VI., originally named Angelo Braschi, was born at Cesena, December 27, 1717. He was selected by Benedict XIV. as his secretary; and under Clement XIII., he was named to several important appointments, which led finally, under Clement XIV., to his elevation to the cardinalate. On the death of Clement XIV., Cardinal Braschi was chosen to succeed him, February 15, 1775. The conflict with the civil power in the various states of Europe, in which, from the days of Innocent XI., the Roman see had been almost unceasingly involved to a greater or less degree, assumed under P. what may be called its complete and scientific development. His relations to the Emperor Joseph of Austria and the Grand Duke Leopold of Tuscany, who persisted in the reformation of the religious orders, &c., were far from amicable.

The internal administration of P., however, was enlightened and judicious. To him, Rome owes the drainage of the Pontine Marsh, the improvement of the port of Ancona, the completion of the church of St. Peter's, the foundation of the new Museum of the Vatican, and the general improvement and embellishment of the city. These and other similar projects were interrupted by the outbreak of the French Revolution. In 1793, a popular tumult at Rome, which was caused by the imprudence of a French political agent named De Basseville, and which resulted in his death, gave the French Directory an opportunity of hostile demonstrations against the pope. In 1796, Bonaparte took possession of the Legations, and afterwards of the March of Ancona, and by a threatened advance upon Rome, extorted from P., in the Treaty of Tolentino, the surrender of these provinces to the

Cisalpine Republic, together with a heavy war contribution. The year 1797 was marked by a continuance of the same vexatious measures; and at length the Directory ordered the invasion of Rome; Berthier entered the city, February 10, 1798, and took possession of the castle of St. Angelo. P. was called on to renounce his temporal sovereignty, and on his refusal, was seized, February 20, and carried away to Siena, and afterwards to the celebrated Certosa, or Carthusian monastery, of Florence. On the threatened advance of the Austro-Russian army in the following year, he was transferred to Grenoble, and finally to Valence on the Rhone, where, worn out by age and by the rigor of confinement, he died in August 1799, in the 82d year of his age and the 24th of his pontificate.—PIUS VII., originally Gregory Barnabas Chiaramonte, was born at Cesena in 1742. He entered the Benedictine order at an early age, and was employed in teaching philosophy and theology at Parma, and afterwards at Rome. He was appointed Bishop of Tivoli; and afterwards, being created a cardinal, was translated to the see of Imola.

After the death of Pius VI., Cardinal Chiaramonte was chosen his successor (March 14, 1800). Rome, which, up to this time, had been in the occupation of the French, was now restored to the papal authority, and in the July of that year, P. VII. entered into his capital; and in the following year, the French troops were definitively withdrawn from the papal territory, with the exception of the Legations. From this time forward, P., ably seconded by his secretary of state, Cardinal Consalvi, was destined to occupy a prominent place in the political as well as the ecclesiastical affairs of Europe. Bonaparte had resolved to restore religion in France on the ancient basis of connection with Rome. With this view, he entered into negotiations with P. VII. for the establishment of a concordat suited to the new order of things which had arisen. These negotiations were conducted at Paris, and were attended with many difficulties and delays, until at length Cardinal Consalvi repaired in person to the conference, and, by his energy and decision, disentangled the complicated embarrassments in which it was involved. It was agreed to at Paris, July 15, 1801; ratified in Rome, August 14; and published in Notre-Dame on Easter Sunday 1802. But simultaneously with the concordat, and as if forming part of the same arrangement, was published a code of what were called 'Organic Laws,' seriously affecting the discipline of the church on marriage, on the clergy, and on public worship, which had never been submitted to P., and to which he not only had not consented, but to which he found himself compelled to offer every opposition. For the first year which succeeded the publication of the concordat, no occasion of difficulty arose; but conflict of principles was in the end inevitable. In 1804, Bonaparte having resolved on assuming the imperial crown, invited P. to come to Paris for the purpose of crowning him, and the pope, although with much hesitation, consented. He took advantage of his visit to demand the recall or modification of the articles, but without success; and although, during his visit to Paris, he was treated with great distinction and reverence, his relations with Napoleon from that date began to assume a less friendly character.

The French emperor now proceeded from one petty outrage to another, until finally, in February 1808, the French troops, under General Miollis, entered Rome, and took possession of the castle of St. Angelo; and on the 2d of April, a decree was issued annexing the provinces of Ancona, Fermo, Urbino, and Macerata to the kingdom of Italy. P., besides protesting against the usurpation, declared himself a prisoner in the French hands, and confined himself to his palace. The papers of the cardinal secretary were violently seized, and the pope was compelled to appoint a pro-secretary; and finally (May 17, 1809), the usurpation was consummated by a decree annexing Rome and all the remaining papal territory to the French empire. This was the signal for the pope abandoning his lengthened policy of forbearance. On June 10, P. issued a bull of excommunication, directed (without naming Napoleon) against the perpetrators and abettors of the invasion of the rights and the territory of the holy see. Soon afterwards, the French general ordered the removal of the pope from Rome; and P. without offering any resistance beyond the declaration that he yielded to force, was removed, first to Florence, then to Grenoble, thence for a longer time to Savona, whence, in June 1812, he was finally transferred to Fontainebleau. During this prolonged captivity, P. firmly but quietly resisted every effort to compel or seduce him from his policy. At Fontainebleau, he was treated with much external respect; and on Napoleon's return from the Russian campaign, in December 1812, orders were given that the cardinals with certain exceptions, should be admitted to the presence of the pope. Under much pressure, both from the emperor himself—who is alleged by some to have acted with great rudeness, and even with personal violence—and from the ecclesiastics to whom the emperor confided his plans, P. was induced to sign a new concordat, an important provision of which was the recognition of the annexation of the Roman states to the empire.

Having obtained the concession, Napoleon at once permitted the absent cardinals to return, and of these many remonstrated so earnestly against the concordat, that, on March 24, P. wrote to revoke his consent. Napoleon took no notice of the revocation; nor was it till after the disasters of 1813 that he began to seek an accommodation. P. refused to treat until he should be restored to Rome; and on January 22, 1814, orders were sent for his immediate return to his capital. Unattended by his cardinals, he was escorted to Italy, and remained at Cesena until the fatal campaign of the spring of 1814 placed Paris in the hands of the allies, when P. re-entered Rome amidst the gratulations of the people on May 24, 1814—a day since that time held sacred in the Roman calendar. During the Hundred Days, he was again compelled to leave Rome; but after the campaign of Waterloo, he finally resumed possession, which was undisturbed for the rest of his life, and which extended to the whole of the ancient territory, including the Legations.

The last years of his pontificate were devoted to measures of internal administration; and under the enlightened government of Cardinal Consalvi, were marked by much wisdom and moderation. But the administration chiefly by ecclesiastics and the secrecy of law procedure were resumed. P. repressed, too, with great vigor the disorder and brigandage which the long wars had introduced, and a whole village of notorious and incorrigible criminality, that of Somma, was razed to the ground in 1819. He was equally vigorous in repressing secret societies, especially that of the Carbonari (q. v.). The ecclesiastical measures of his later period were also of much importance. In 1814, he formally restored the suppressed order of the Jesuits (q. v.). In 1817 and the following years, he concluded concordats with Naples, with Prussia, Wurtemberg, and other courts of Germany. In this and every other period of his life, P. was a model of gentleness, simplicity, benevolence, and Christian charity. In July 1823, having reached the patriarchal age of 81, he fell accidentally and broke his thigh. He sank gradually, and died August 20, 1823.

PIUS IX., GIOVANNI MARIA MASTAI FERRETTI, occupant of the papal chair during one of the most eventful periods in the history of the papacy, was born at Sinigaglia, May 13, 1792. He was originally destined for the military profession—the Noble Guard; but symptoms of an epileptic tendency led to his abandoning his intended profession. He received holy orders, and after exercising his ministry for a time in Rome, was sent as 'auditor' of the vicar apostolic to Chili. Having been successively archbishop of Spoleto and of Imola, nuncio, and cardinal, he was, on the death of Gregory XVI. in 1846, elected 'by acclamation' to succeed him. He took the name of Pius IX., and entered at once on a course of reforms, by which he hoped to establish the papal government on a popular, but yet on a firm basis. He resolved to extirpate all abuses of administration, to withdraw the restrictions of personal liberty, to secularize the local administration, and to extend the rights of self-government. His first step to this end was to grant an amnesty; and this measure, however humane and necessary, had the result of drawing together into the Roman states a body of men whom an unhappy experience of foreign exile had embittered against the existing order of things. For a time, the reforming policy of P. carried with it the affections of the people; but he soon fell short of the expectations which he had created. The outbreak of the French Revolution of February 1848 precipitated the crisis of popular discontent. In November of that year, Count Rossi, whom the pope had appointed his minister, was assassinated; and violent demonstrations were daily employed to compel the pope's assent to measures which he repudiated. Having at first confined himself to the Quirinal, he at length fled secretly from Rome to Gaeta, a Neapolitan seaport near the Roman frontier. A republic was proclaimed in Rome, the provisional heads of which proceeded to a complete and radical remodelling of the civil government of the state. P. from his exile addressed a remonstrance to the various sovereigns.

In April 1849, a French expedition was sent to Civita Vecchia, which eventually advanced upon Rome, and, after a siege of about thirty days, took possession of the city, and established a French army of occupation within the Roman state. The pope's government was re-established, but he himself did not return till 1850, when he again entered upon the administration. In consequence of the unsettled condition of Italy, and the failure of many of his early measures of improvement, he declared himself unable to proceed with the reformations which he had contemplated. After that time, his authority was maintained without interruption; but the discontent continued. After the war for the unification of Italy, the Legations, Ancona, and a considerable part of the papal territory southward in the direction of Rome, were annexed to the kingdom of Italy, but P. persistently refused to cede any portion or to enter into any compromise. His ecclesiastical administration continued very active, and proceeded upon the strongest assumption of the right of independent action on the part of the church. In this view, he re-established the hierarchy in England, he sanc-

tioned the establishment in Ireland of a Catholic university, and condemned the principles upon which the Queen's Colleges in that country were constituted. He concluded with Austria a concordat much more favorable to church authority than the existing ecclesiastical laws had permitted. See CONCORDAT. In 1854, he issued a decree propounding as a doctrine of the church, the faith of the Immaculate Conception of the Blessed Virgin Mary (q. v.). In the internal administration of his states, notwithstanding the embarrassed condition of finances produced by the curtailment of his territory, he introduced many ameliorations, and did much for the advancement and improvement of the city of Rome and of its institutions. In this he was aided by the voluntary contributions of the several churches, as well in special gifts as in the organization of the permanent tribute called Peter-pence (q. v.).

In 1864, on occasion of the centenary of the martyrdom of St. Peter, he brought together at Rome a large assemblage of bishops, and subsequently, on occasion of the canonization of the Jesuit martyrs of Japan. But the most important event of his pontificate was the convocation of the Vatican Council (see COUNCIL), at which bishops from all parts of the Catholic world assembled in Dec. 1869. For the discussions of this council, see POPE. It was adjourned in July 1870, after it had proclaimed the celebrated decree of the Infallibility of the Pope, when on a subject of faith or morals he issues a decree *ex cathedra* to the universal church. Soon after the adjournment, the Italian army occupied Rome, and declared it the capital of the kingdom of Italy. P. renewed with all solemnity his oft-repeated protest, and refusing an offered dotation, and all other proposals of accommodation, from that date declared himself a captive in the Vatican, to which he strictly confined himself. In June 1871, he completed the 25th year of his pontificate, thus exceeding the term of all previous pontificates except that assigned to St. Peter, and falsifying in his own person the traditional prediction that no pontiff would ever 'see the days of Peter.' His health was for some years precarious; but with the exception of occasional interruptions, he continued to attend personally to all the public affairs, civil as well as ecclesiastical, of his office. He died 7th February 1878.

PIVOT, the point on which a body revolves, has a like signification in military affairs—the pivot-man being that soldier who marks the center while a line is wheeling.

PIYADASI, one of the names of the celebrated King As'oka. See BUDDHISM, INDIA. He is often designated by this name in inscriptions.

PIZARRO, FRANCISCO, the conqueror of Peru, was an illegitimate son of Gonzalo Pizarro, a colonel of infantry, and a soldier of some distinction. He was born at Truxillo, in Estremadura, Spain, about 1471. Of his youth, little is known, but it appears that he was wholly neglected by his parents, was taught neither to read nor write, and that in his youth his principal occupation was that of a swineherd. Abandoning this uncongenial employment, he sought the port of Seville, and there embarked, to seek fortune in the New World. He was in Hispaniola in 1510; later, he joined Balboa, and was with that cavalier when he crossed the Isthmus of Panama, and discovered the Pacific. In 1515, he was engaged in traffic with the natives on the shores of the newly-discovered ocean, but was afterwards chiefly employed in military service, in which he showed great bravery, resource, and power of endurance. About this time, when a fresh and powerful impulse was given to adventure by the splendid achievement of Cortes, rumors of a country far south, in which gold and silver were said to be as abundant as iron in Spain, reached Panama, and kindled P.'s ambition. He formed a sort of co-partnership with Diego de Almagro, an adventurer and a founding like himself, and Hernando Luque, an ecclesiastic; and with the funds which the three friends amassed, they were enabled to fit out a small expedition, of which P. took command. In November 1524, he set sail southward, but went no further than Quemada Point. Making an agreement (dated March 10, 1526), that all lands, treasures, vassals, &c., that should be discovered were to be equally divided between them, the three friends, P., Almagro, and Luque, organized a second expedition, consisting of two ships, which set sail for the South Seas. Having reached the port of Santa, in lat. about 9° S., and having really discovered Peru, P. returned to Panama, carrying with him, however, many beautiful and valuable ornaments in gold and silver, which he had obtained from the friendly and generous natives, as well as specimens of woollen cloths of silky texture and brilliant hue, and some lamas and apacacs.

Unable to find in Panama a sufficient number of volunteers for the invasion of the newly-discovered country, the indomitable adventurer returned to Spain in 1528, narrated the story of his discoveries before Charles V. and his ministers, described the wealth of the territories, and showed, as proof, the gold ornaments and utensils, the manufactures, &c., which he had brought with him. The result of his representations was, that the right of the discovery and conquest of Peru was secured to him, and honorable

titles—among others, those of Governor and Captain-general of Peru—were conferred on him. On his side, he agreed to raise a certain number of followers, and to send to the crown of Spain a fifth of all the treasures he should obtain. Returning to Panama, he set sail for Peru for the third and last time, with a well-equipped but small force, the number being not more than 180 men, of whom 27 were cavalry. The chief events of the conquest of Peru are detailed at sufficient length in the article PERU, and also the articles ALMAGRO and ATAHUALPA. Within ten years, the great conquistador made the empire of Peru his own; but he who had surmounted so many stupendous difficulties, who had broken through the lofty barrier of the Andes, and, with his group of followers, been a victor in so many fields, fell a victim to a conspiracy, June 26, 1541.

P. was a soldier of the most undoubted courage, inflexible constancy of purpose, and infinite resource; yet his success in Peru appears to have been more the result of chance than of calculation. His boldest stroke was the seizure of the Inca Atahualpa (q. v.), when surrounded by thousands of his followers; but in doing so, he deserved credit neither for originality nor policy, because the idea was borrowed from Cortes, and the step itself was so foolhardy and desperate, that its success can be regarded only as luck. Although on many occasions he appears to have been guided by noble and generous impulses, he was eminently selfish, perfidious, and relentless. His conquest of Peru is a drama in every act of which there is bloodshed; but the drama is at least consistent to the end. P. lived a life of violence, and died a violent and bloody death.

PIZARRO, GONZALO, threw in his fortunes with those of his brother Francisco, on the occasion when that leader returned to Spain in 1528. He was, like the great conqueror, illegitimate. He became a soldier at an early age, distinguished himself, before he joined his brother's expedition, by his skill in martial exercises, and when he reached Peru, was esteemed the best lance in the Spanish troop. The territory of Quito was assigned to him by Francisco, and he was enjoined to undertake an exploring expedition to the east, where a land, reputed to be extremely rich in spices, was said to lie. At the head of 850 Spaniards and a great concourse of Indians, P. set out on his famous journey in the beginning of 1540. Marching east, they reached a country traversed by lofty branches of the Andes. Here the icy winds benumbed the limbs of the adventurers as they rose to the higher plateaux, and, rendered helpless by the cold, many of them sank and died. Descending the eastern slopes of the Andes, they reached the 'Land of Cinnamon'; but as they could not transport the trees across the mountains, their discovery was almost valueless. Hearing of a land abounding in gold at the distance of ten days' journey, the leader resolved to reach it. Pushing forward, the Spaniards entered great forests, where often they had to hew a passage with their axes. Their clothes were now torn to shreds, and their provisions had been long exhausted. They killed and ate the dogs they had brought with them, after which they lived on the herbs and dangerous roots of the forest. At length they struck the broad but desolate waters of the Napo, an important affluent of the Amazon. On the surface of this broad river, no vessel floated, and it ran amid gloomy woods, the silence of which was undisturbed save by the sound of the rushing waters. Here P. caused a rude bark to be constructed for the transport of the baggage and of the weaker travelers. Francisco de Orellana was intrusted with the command of the vessel.

P., hearing of a populous nation at the distance of a few days' journey, who dwelt near the confluence of the Napo with a larger river, sent forward Orellana to obtain and bring back supplies for the starving travelers, who had eaten the last of their horses, and were now reduced to the leather of their saddles and belts. Orellana reached the Amazon; but, unable either to obtain supplies, or to return against the current of the river, abandoned the expedition, and with his fifty followers resolved to sail down the Amazon, reach the Atlantic, and make for Spain. This wonderful design was successfully carried out. P., after waiting in vain for the return of the barque, resolved to return to Quito, which, after enduring terrible sufferings, and seeking fruitlessly for the rich regions of which he had heard so much, he reached in June 1542, after an absence of more than two years. The fatal character of this expedition may be inferred from the appearance the travelers presented on their return. Half of the 4000 Indians had perished, and of the Spaniards, only eighty remained; and these, clad in skins, blackened by the sun, and wasted by hunger and fatigue, with long matted locks, seemed like a troop of spectral savages. This expedition stands unmatched in the annals of American discovery for its dangers and sufferings, for the length of their duration, and for the heroic fortitude with which they were endured. For the fate of Gonzalo P., see article PERU.

PIZZICATO (Ital. twitched), abbreviated *pizz.*, a phrase used in Music for the violin or violoncello, to denote that the strings, instead of being played as usual by the bow, are to be twitched

with the fingers in the manner of a harp or guitar. The pizzicato is much used in accompaniments, as sounds thus produced do not cover the voice; it is also used in symphonic effects. The ordinary mode of playing is restored by the letters *c. a. (col arco, with the bow)*.

PIZZO, a seaport of South Italy, 24 miles west-south-west of Catanzaro. At P., Murat (q. v.) was taken, tried, and shot. Pop. 6400.

PLACE'NTA, or **AFTER-BIRTH**, a temporary organ that is developed within the uterus during pregnancy, and is, as its popular name implies, expelled from the maternal organism shortly after the birth of the child or young animal. It is a spongy vascular mass, existing in some form or other in all mammals, excepting the *Marsupialia* and *Monotremata*, as an appendage to the foetal membrane called the *chorion*. In the human subject (fig. 1), it is of considerable size at the period of delivery, being

Fig. 1.—Human Placenta (half of it being split in two) and Umbilical Cord.

of a rounded or oval form, with a diameter of 6 or 8 inches, and a thickness of somewhat more than an inch. Its outer surface, which, till the period of its detachment and expulsion, is attached to the walls of the uterus, is uniform and level (unless it has been morbidly adherent), being covered by a membrane, shortly to be noticed, called the *decidua serotina*; and on peeling off this membrane, the various lobes of which the placenta is composed are apparent. The internal or free surface is smooth and shining, and gives attachment to the umbilical cord or navel-string, which connects it with the foetus. To render the mode of formation of the placenta clear, we must premise that the impregnated ovum, when it reaches the uterus, is invested with an outer membrane, the *chorion*, which forms a shut sac, externally covered with short villi. As the ovum advances in age, these villi diminish in number, until few remain, except at that part of the chorion which is in contact with the uterus; and here, about the second month (in the human subject), they divide into branches, as shown in fig. 2.

While these changes are going on in the membrane of the

Fig. 2.—Diagrammatic Section of a Human Pregnant Uterus, with the contained Ovum:

u, uterus; *l*, oviduct (or Fallopian tube); *c*, cervix uteri (or neck of the womb); *du*, decidua uteri; *ch*, decidua reflexa; *ds*, decidua serotina; *ch*, chorion; *am*, amnion; *al*, allantois; *nb*, umbilical vesicle; *z*, villi, which form the fetal part of the placenta; *z'*, villi over the rest of the chorion, which, in the human subject, take no part in the placental function.

ovum, the uterus is also undergoing modification; and it is on the

nature and extent of these uterine changes that the character or type of the placenta depends. There are two such types, the first of which is best represented by the human placenta, and the latter by that of the pig.

In animals exhibiting the first type of placental structure, the mucous membrane lining the uterus undergoes a rapid growth and modification of texture, becoming connected with the *membrana decidua*, which is so called from its being thrown off at each parturition. For brevity, it is usually termed the *decidua*. This decidua is from an early period separable into three portions the *decidua vera*, or *decidua uteri*, which lines the general cavity of the uterus; the *decidua reflexa*, which immediately invests the ovum; and the *decidua serotina*, which is merely a special development of a part of the decidua vera at the part where the villi of the chorion are becoming converted into the fetal portion of the placenta. The arrangement of these layers is distinctly seen in fig. 2. At first, the villi of the chorion lie loosely in the corresponding depressions of the decidua; but subsequently, the foetal and maternal structures (the villi and the decidua vera) become closely united, so as to form one inseparable mass, by the following means: the deeper substance of the uterine mucous membrane in the region of the placenta is traversed by vessels which enlarge into what, in the case of the veins, are termed *sinuses*, dip down between the villi, 'and at last swell round and between them, so that finally the villi are completely bound up or covered by the membrane which constitutes the walls of the vessels, this membrane following the contour of all the villi, and even passing, to a certain extent, over the branches and stems of the tufts.'

—Goodsir's *Anatomical and Pathological Observations*, p. 60.

The pure maternal blood is conveyed to the placenta by what are termed, from their tortuous course, 'the curving arteries' of the uterus, and is returned by the large veins termed sinuses. 'The foetal vessels,' says Dr. Carpenter, 'being bathed in this blood, as the branchiæ of aquatic animals are in the water that surrounds them, not only enable the foetal blood to exchange its venous character for the arterial, by parting with its carbonic acid to the maternal blood, and receiving oxygen from it, but they also serve as rootlets, by which certain nutritious elements of the maternal blood (probably those composing the liquor sanguinis) are taken into the system of the foetus. It is probable, too, that the placenta is to be regarded as an excretory organ, serving for the removal, through the maternal blood, of excrementitious matter, whose continued circulation through the blood of the foetus would be prejudicial to the latter.'—*Human Physiology*, 3d ed. pp. 1013, 1014. Moreover, the recent investigations of Bernard show that the placenta secretes, like the liver, the saccharine matter known as Glycogen (q. v.), which probably takes part in keeping up the animal heat. The vascular connection between the foetus and the placenta is effected by the umbilical vein (containing arterial blood) and the two umbilical arteries (containing venous blood), all of which lie in the umbilical cord which connects the Foetus (q. v.) with the placenta. The placenta may be formed at any point of the uterus, but is most commonly on the left side. Occasionally (in 11 cases out of 600, according to Naegele), it is situated partially or entirely over the mouth of the womb (*os uteri*), in which case dangerous flooding takes place previous to or at the period of labor. This condition is known as *placenta prævia*, and under ordinary management, 'one in three of the mothers are lost, and more than 65 per cent. of the children.'—Churchill, *Theory and Practice of Midwifery*, 3d ed. p. 473. By substituting the detachment and extraction of the placenta for the old method of turning the child *in utero* Professor Simpson finds that the mortality sinks to one in fourteen of the mothers, but slightly rises (to 69 per cent.) in the case of the children.

Another difficulty in midwifery practice, but far less serious than the preceding, is undue retention of the placenta. In ordinary cases, the average interval between the birth of the child and the expulsion of the after-birth is a quarter of an hour. When the expulsion does not take place within an hour or an hour and a half, the case is regarded as coming under the head of 'retained placenta.' It occurs in about 1 case in 400, and in these cases is fatal to about one mother in five; the cause of death being hæmorrhage. The principal causes of retention are either imperfect and insufficient, or irregular contraction of the womb, after the birth of the child. In the first of these cases, if the uterus cannot be excited to sufficient action, the placenta must be withdrawn by steady traction of the umbilical cord, and if it fail, extraction by the introduction of the hand (an operation always to be avoided if possible) must be resorted to; in the latter case, manual extraction is commonly necessary. Sometimes, in consequence of inflammatory or other affections of the placenta, there may be adhesion between its outer surface and the inner surface of the womb. This is the most dangerous form of retention, there being usually excessive flooding, and additionally the peril arising from the decomposition of any portion that cannot be removed without undue violence.

The placenta acquires its proper character, in the human sub-

ject, during the third month, and it subsequently goes on increasing to the full period of gestation. At about the fourth month, the blood, moving through the enlarged uterine vessels, produces a peculiar murmur, which is known as the *placental bruit*, resembling the sound made by blowing gently over the lip of a wide-mouthed phial, and increasing in intensity and strength as pregnancy (of which it is one of the characteristic signs) advances.

In animals exhibiting the second type of placental structure—as, for example, the pig—the placenta is comparatively simple in its structure. 'No *decidua* is developed; the elevations and depressions of the unimpregnated uterus simply acquire a greater size and vascularity during pregnancy, and cohere closely with the chorionic villi, which do not become restricted to one spot, but are developed from all parts of the chorion, except its poles, and remain persistent in the broad zone thus formed throughout foetal life. The cohesion of the foetal and maternal placenta, however, is overcome by slight maceration or post-mortem change; and at parturition, the foetal villi are simply drawn out like fingers from a glove, no vascular substance of the mother being thrown off.' Professor Huxley, from whose *Elements of Comparative Anatomy* (1864, p. 103) the preceding extract is borrowed, follows the opinion adopted by De Blainville, Von Baer, Eschricht, Milne-Edwards, Gervais, and Vogt in regarding 'the features of the placenta as affording the best characters which have yet been proposed for classifying the monodelphous [or placental] mammals.' He proposes to apply the term *deciduate* to those animals whose placenta presents the human type, and which throw off a *decidua*; and to term those animals *non-deciduate* in which the placenta is constructed on the same plan as that of the pig. 'Thus,' he observes, 'man; the apes, or so-called *Quadrumanæ*; the *Insectivora*; the *Cheiroptera*; the *Rodentia*, to which the lowest apes present so many remarkable approximations; and the *Carnivora*, are all as closely connected by their placental structure as they are by their general affinities. With the pig, on the other hand, the ungulate quadrupeds, and the *Cetacea* which have been studied, agree in developing no *decidua*, or, in other words, in the fact, that no vascular maternal parts are thrown off during parturition. But considerable differences are observed in the details of the disposition of the foetal villi, and of the parts of the uterus which receive them.

Thus, in the horse, camel, and *Cetacea*, the villi are scattered as in the pig, and the placenta is said to be *diffuse*; while in almost all true *Ruminants*, the foetal villi are gathered into bundles or cotyledons (fig. 8), which in the sheep are convex, and are re-

Fig. 8.—Uterus of a Cow in the middle of Pregnancy, laid open: v, vagina; u, uterus; ch, chorion; c, uterine cotyledons; c', foetal cotyledons.

ceived into cups of the mucous membrane of the uterus; while in the cow, on the contrary, they are concave, and fit upon corresponding convexities of the uterus.'

The remarks which have been made on the functions of the human placenta, are equally applicable to all placental mammals generally.

The *diseases* of the human placenta had not been studied with any accuracy, until the subject was taken up by Professor Simpson. This distinguished physician and subsequent observers have ascertained that the placenta is liable to (1) congestion, ending in the effusion of blood into the substance of the organ upon its surfaces, or between the membranes; (2) Inflammation, giving rise to adhesions, or terminating in suppuration, which may occasion very serious constitutional disturbances; (3) Partial or entire hypertrophy or atrophy; and (4), Fatty degeneration, affecting its

small vessels. Whatever be the form of disease by which the placenta is attacked, the result is usually fatal to the fœtus.

PLACENTA, in Botany, a membrane of the interior of the Germen (q. v.) or ovary, to which the ovules are attached either immediately or by Umbilical Cords (q. v.). The placenta sometimes appears as a mere thickening of the walls of the germen. In many cases, it is a more decided projection from the walls of the germen. When thus connected with the walls of the germen, the placenta are described as *parietal* (Lat. *paries*, a wall). But in some plants, the placenta of the different cells of the germen are united together in a column in its axis, and they are then described as *axile*. This distinction is of great importance as characterizing different natural orders. Parietal placenta are formed where the edges of carpellary leaves unite; but great difficulty has been experienced by vegetable physiologists in explaining the formation of axile placenta; some regarding them as also originally formed in this manner, and others as formed in a quite different manner from the axis itself; nor is it impossible that both theories may be correct as to different orders of plants. It is certain that in many cases in which the placenta appear as axile, they are formed from the edges of the carpellary leaves which fold in to meet in the axis, and form *Dissepiments* (q. v.) between the cells of the germen. The number of placenta corresponds with the number of carpels in the germen, or appears to be the double of it, each carpel producing two rows of ovules instead of one. See figures in article PISTIL.

PLACE'NZÁ. See PIACENZA.

PLACETUM REGIUM, called also PLACET EXEQUATUR, LETTRES PATENTES, is an act or instrument executed in virtue of the privilege claimed by the government in certain kingdoms to exercise a supervision over the communications of the Roman pontiff with the clergy and people of those kingdoms, and to suspend or prevent the publication of any brief, bull, or other papal instrument which may appear to contravene the laws of the kingdom, or to compromise the public interest. The early Christian emperors, it is well known, freely stretched their legislation into the affairs of the church; and one constant cause of conflict between church and state, in the mediæval period was the attempt on the part of the sovereigns to control the free intercourse of the pope with the several churches. In the Pragmatic Sanction in France, and in the similar legislation of Spain, Portugal, Sicily, and the Low Countries during the 15th c., the claims of the state on the same head are more than once asserted; and among the so-called 'liberties' of the later Gallican Church was a certain, though not a complete subjection to the state in this particular; but it was in the German states that this claim was most distinctly asserted, and most formally embodied in the constitutional law. The principle upon which the Peace of Westphalia so far as regards its religious provision is based, is that the will of the sovereign of the state is supreme and final in all the concerns of religion. *Cujus regio illius et religio* ('Whose the territory, his also the religion'), became the maxim of church government; and, of course, within certain limits, the Catholic sovereigns acted as freely upon it as the Protestant.

This intermixture of the spiritual and the temporal prevailed especially in the mixed governments of the ecclesiastical sovereigns of Germany, the prince-bishops of the Rhine; but without the same foundation, the system was carried to its height in Austria under Joseph II. (see FEBRONIANISM, PIUS VI.), the excessive minuteness of whose ecclesiastical ordinances procured for him the sobriquet of 'The Sacristan.' Under him, all pontifical bulls, briefs, and constitutions, and all the ordinances of the local bishops, were made subject to the imperial censorship, and it was forbidden to publish any of them without its receiving the *placet* of the emperor. The only exception, in the case of pontifical decrees, regarded those emanating from the Roman Penitentiary (q. v.), which, as being of their nature secret, were not held subject to revision. In Prussia, the same law was enforced, as also in Baden and Saxony, no less than in the Protestant governments of Würtemberg, Saxe-Gotha, Saxe-Weimar, &c. These claims of the state had always been the subject of protest on the part of the Roman see, but the church, nevertheless, had been compelled to acquiesce silently in the enforcement. In many cases, however, they have led to serious disputes, of which the mixed-marriage question in Prussia furnished a few years ago a very remarkable example. And since the ascendancy obtained by Prussia in the German Empire at the close of the Franco-German war, the system of church legislation has undergone a complete change, the details of church government being largely taken into the control of the state, and obedience to the new code of church laws being exacted from the clergy under penalty of forfeiture of income, of deprivation of office, and in some cases of exile.

PLA'COID FISHES, an order of fishes, in the classification proposed by Agassiz, characterized by having *placoid* (Gr. *plax*, a broad plate) scales, irregular plates of hard bone, not imbricated,

but placed near together in the skin. These scales or plates are of considerable size in some fishes, but in others they are very small tubercles, as in the dogfish, of which the skin forms fine-grained shagreen. Agassiz includes among the P. F. those cartilaginous fishes which have no scales. The order is exclusively composed of *Cartilaginous fishes* (q. v.). The existing P. F. are

Placoid Scales:
a and *b*, placoid scales of *Abeuteres trosulus*, one of the Bali tidæ,
 from Australia; *c*, *d*, *e*, scales from different parts of the body of
Aleuteres variabilis.

few in comparison with the fossil genera and species. Placoid scales are often elevated in the middle, the center sometimes rising into a strongly projecting point or spine. They exhibit great variety of forms, sometimes even in different parts of the same fish.

PLA'GAL, a musical term, principally applicable to *Canto Fermo* and signifying collateral. Gregory the Great, in revising the labors of Ambrose, and remodelling the Plainsong (q. v.) of the church, added to the scales of Ambrose, which he distinguished as authentic, certain other collateral scales, which he called plagal, possessing the peculiarity of having the octave so divided that the fourth was above the fifth. Melodies are now known as plagal which have their principal notes contained between the fifth of the key and its octave or twelfth. The cadence, consisting of the subdominant harmony followed by the tonic, is called the plagal

PLAGIOSTOMI (Gr. transverse-mouthed), an order of fishes, in the system of Müller, containing the cartilaginous fishes with Placoid (q. v.) scales, and divided into two sub-orders, one containing sharks, and the other rays. The ♀ have five or more gill-openings. They have no air-bladder. Impregnation takes place before the eggs are deposited, and the males are furnished with *claspers*.

PLAGUE, a very malignant kind of contagious fever prevailing at certain times and places epidemically, characterized by buboes or swellings of the lymphatic glands, by carbuncles and pectchie, and not apparently furnishing any security against its recurrence in the same individual. For a history of the origin of the plague in the far East (China), and its gradual spread, under the name of the *Black Death* (q. v.), through Asia and Europe, in the 14th c., the reader is referred to Hecker's *Epidemics of the Middle Ages* (1844), published by the Sydenham Society). Its true and permanent home seems to be in the regions bordering upon the eastern extremity of the Mediterranean. At different periods of the 15th, 16th, and 17th centuries, it visited Western Europe. It last attacked London and almost all England in the years 1663—1665; while so late as 1720, it destroyed nearly half the population of Marseille; and seventy years afterwards, prevailed in Russia and Poland, since which time it has been almost unknown in Western Europe. It is now limited chiefly to Egypt, Syria, Anatolia, Greece, and Turkey, occasionally extending northward towards Russia, and westward as far as Malta.

The disease usually commences with a sensation of intense weariness and fatigue, slight shivering, nausea and sickness, confusion of ideas, giddiness, and pain in the loins. These symptoms are rapidly followed by increased mental disturbance, with occasional stupor and delirium, by alternate pallor and flushing of the face, by suffusion of the eyes, and a feeling of intense constriction in the region of the heart. Darting pains are felt in the groins, armpits, and other parts of the body, which are soon followed by enlargements of the lymphatic glands, or *buboes* (which sometimes appear on the first and second day, sometimes not till near the close of the disease, and sometimes are altogether absent), and by the formation of *carbuncles* on various parts of the body.

As the disease advances, the tongue becomes dry and brown, while the gums, teeth, and lips are covered with a dark fur; the bowels, at first constipated, become relaxed, the stools being dark offensive, and sometimes bloody. The power of the will

on the muscles is much impaired; and altogether the patient resembles a person under the influence of intoxication. Throughout the disease, there is more or less tendency to faintness; and usually about the second or third day, petechial spots, livid patches like bruises, and dark stripes (called *ruivies*), appear upon the skin, especially in severe cases. These discolorations are owing to the extravasation of blood, and are often accompanied with hæmorrhagic discharges from the mucous membranes. In fatal cases, the pulse gradually sinks, the surface becomes cold and clammy, blood oozes from the mucous surfaces, there is coma, or low delirium; and death occurs usually in five or six days, either without a struggle, or preceded by convulsions.

Great difference of opinion exists as to the cause of plague. Some maintain that it is propagated exclusively by a peculiar contagion; others, while admitting its contagious nature, maintain that it may also be spontaneously engendered by endemic or epidemic influences; while others, again, reject the contagion view altogether, and assert that it originates exclusively in local causes or epidemic influences. Of these three views, the great mass of evidence goes to show that the second is the correct one. Whatever may be the cause of the disease, temperature appears to exert a considerable influence over it. In tropical climates, the disease is unknown, and the cold weather of northern climates has been observed to check its ravages. In Europe, it has always been most fatal in the summer and autumn, especially in September. Thus, in the great plague of London in 1665, the deaths from the plague were, in June, 590; in July, 4129; in August, 20,046; in September, 26,230; in October, 14,373; in November, 3449; while in December, they were less than 1000.

The exact nature of the disease is unknown. A poison whose characters evade all chemical and microscopical examination, is absorbed, and alters at once, or after a short stage of incubation the composition of the blood and the condition of the tissues.

With respect to treatment, little can be done to arrest the progress of the disease in any individual case. The patient should, if possible, be removed at once from the source of the disease; he should be exposed freely to fresh air; his secretions should be fully regulated, and his strength supported as far as possible. Friction with olive oil has been strongly recommended, but subsequent experience has not confirmed the first reports in its favor. But although treatment is comparatively valueless, much may be done towards guarding against the attacks of the disease. There can be little doubt that it is in consequence of the free external use of cold water, perfect cleanliness, moderate habits of life, and superior ventilation, that European (especially English) residents in the infected cities of the Levant are comparatively exempt from this disease. It is very possible that inunction of the body with olive oil may be (as has been asserted) a useful prophylactic agent, although it fails to cure the disease. It is almost needless to add, that all unnecessary communication with the sick, or contact with clothes or others matter that may have been infected with the poison, should be as much as possible avoided.

PLAICE (*Platessa vulgaris*), a species of Flounder (q. v.), much resembling the common flounder, but rather broader in proportion to its length; the upper surface of the body and the fins olive-brown, marked with large bright orange spots; a row of similar spots on the dorsal fin and on the anal fin; no tubercular asperities on any part of the body, but a curved row of bony tubercles on the eye-side of the head. The P. inhabits sandy and muddy banks, not in very deep water, and is very abundant on most parts of the British coasts, as well as on those of continental Europe. Like the common flounder, it often ascends slow rivers to some distance from the sea, and it has even been found to thrive well when transferred to fresh-water ponds. It feeds on worms, molluscs, small crustaceans, and young fishes. It has been known to attain the weight of fifteen pounds, but a P. of seven or eight pounds is accounted large. It is taken both by lines and trawls. It is in considerable esteem for the table, although so plentiful in the British markets, that it is in general very cheap.

PLAID, a woollen garment, in the form of a large scarf, to wrap round the body, and used chiefly among the rural population of Scotland. See TARTAN.

PLAIN, in Geography, is an extensive tract of country which, on the whole, preserves a nearly uniform elevation. When referred to the level of the sea, plains may be distinguished into low plains or lowlands, and elevated plains called plateaux or *Tablelands* (q. v.). Plains differ much in appearance, according to the nature of their soil and climate, from the frightful sandy wastes of Africa, to the luxuriant fertility of the South American silvas. They are occasionally crossed by hills of moderate altitude, which, however, are generally detached, and exhibit no connection with any neighboring mountain system. These hills often, as in the North American plains, degenerate into mere undulations, perfectly uniform in structure.

The term 'plains' is, in a limited sense, confined to the plains of Western Europe; those of other parts of the world receiving

special designations, and differing from each other in many important points; thus we have the *Steppes* (q. v.) of Eastern Europe and Asia; the *Deserts* (q. v.) of Arabia and Africa; the *Savannahs* (q. v.) and *Prairies* (q. v.) of North America; and the *Llanos* (q. v.), *Pampas* (q. v.), and *Silvas* (q. v.) of South America. The chief plains of Europe are, the country stretching from the foot of the Carpathians in Galicia to the Ural Mountains (including Poland and Russia), the drainage-area of the Danube in Hungary, and the portion of Europe which is bounded by the Elbe, the Harz Mountains, France, and the sea. Plains of comparatively small extent, but presenting the necessary characteristics in perfection, are found in almost all countries.

PLAINSONG, or **CANTO FERMO** (Ital.), a name given by the Church of Rome to the ecclesiastical chant. It is an extremely simple melody, admitting only notes of equal value, rarely extending beyond the compass of an octave, and never exceeding nine notes, the staff on which the notes are placed consisting of only four lines. The clefs are C and F. St. Ambrose is considered to have been the inventor or systematizer of the Plainsong. His labors consisted in selecting from the extremely complicated system of the Greeks a set of scales sufficiently few and simple for a very rude people. During the two centuries succeeding the death of Ambrose, his institutions fell into utter confusion. Gregory the Great revived and perfected them, recasting them into an *Antiphony*, or authorized body of ecclesiastical music, and brought Plainsong into the state in which it is yet used in the Roman church. See **AMBROSIAN CHANT** and **GREGORIAN CHANT**.

PLAIN'TIFF, in English and Irish Law, is the name given to the person who institutes and maintains a civil action or suit against another, who is called the Defendant. In Scotland, a plaintiff is called a Pursuer. But in both countries, many proceedings and applications of a civil nature are commenced by petition; and hence the party taking the initiative is called the Petitioner.

PLAN, a word frequently applied to all kinds of architectural drawings, but which ought to be limited to those which represent the horizontal sections of the various floors of buildings. Plans show the disposition of the apartments and walls, with the situation of the fireplaces, cupboards, doors, &c.; they, in fact, represent the different stories as they actually appear as seen from above, when the walls are built two or three feet above the level of each floor.

PLANARIA, a genus of worms placed by Cuvier among *Entozoa*, although not parasites, but inhabitants of stagnant waters, because of their great resemblance to some of the entozoic parasites, and particularly to flukes. The species are numerous. Some inhabit fresh, and others salt water; they feed on small annelids, molluscs, &c. They are generally found creeping among confervæ, or on the stems of plants. Many of the larger marine species are able to swim freely by flappings of the broad margins of their bodies. The body of a planaria seems to be entirely gelatinous; but M. de Quatrefages has detected under the skin an arrangement of muscular fibres. Two red specks in the fore-part of the body of many species have been supposed to be eyes; but there is no proof of it. Planariae are hermaphrodite, but copulate for mutual impregnation. Their power of multiplication by division is very great; if an individual be cut in pieces, each piece continues to live and feel, and 'even if it be the end of the tail, as soon as the first moment of pain and irritation has passed, begins to move in the same direction as that in which the entire animal was advancing, as if the body was actuated throughout by the same impulse; and, moreover, every division, even if it is not more than the eighth or tenth part of the creature, will become complete and perfect in all its organs.'—*Rymer Jones*.

PLANCHETTE (a little board) is, as the name implies, a French invention, but its popularity in America has induced the belief of its being of American origin. It consists of a heart-shaped board seven or eight inches at its greatest breadth and length, mounted on two pentagraph wheels, about two inches high, at its widest part, while a pencil fastened at the apex forms its third support. Placed upon a table with a sheet of paper under it, and one or two persons with the necessary qualifications having their hands upon its tablet, setting it in motion, it is found to return answers to questions sometimes of a puzzling character. These answers are asserted by believers in spiritualism to be communications from the spirit-world.

PLANE, in Geometry, is a surface without curvature, and the test of it is, that any two points whatever being taken in the surface, the straight line which joins them lies wholly in the surface. When two planes cross or intersect one another, their common section is a straight line; and the inclination of the planes to each other is measured by taking any point in their common section, and drawing from it two straight lines, one in each plane, perpendicular to the common section; the angle contained by these

lines is the angle of inclination of the planes. When the angle is a right angle, the planes are perpendicular to each other.

PLANE (*Platanus*), the sole genus of trees of the natural order *Platanaceæ*, regarded by many as a sub-order of *Amentaceæ* (q. v.). The flowers are in globose, small, pendulous, long stalked catkins, which give the tree a peculiar appearance in winter; the ovary is one-celled, and contains one or two pendulous ovules. The species of *P.* are few; natives of temperate climates in the northern hemisphere; tall trees, with deciduous large palmate leaves, and smooth whitish bark, which annually scales off in large pieces.—The **ORIENTAL P.** (*P. orientalis*), a native of Greece and the East, was planted by the Greeks and the Romans as an ornamental tree;

Plane Tree (*Platanus orientalis*).

no other tree, indeed, commanding equal admiration; and, for centuries, the youth of Greece assembled under its shade in the groves of Academus, to receive lessons in philosophy. The *P.* is still planted for shade and ornament in the south of Europe. Many fine trees exist in England, but they were at one time much more numerous, great part having died in the end of last century. The spring frosts, and the insufficient duration of the summer for the proper ripening of the wood, render Scotland less suitable for its cultivation; yet there is a tree at Gordon Castle 66 feet high. No tree better endures the atmosphere of a large city, and there are no finer trees within the precincts of London than its *P.* trees. In the East the *P.* attains an immense size. One tree, in the meadow of Buyukdere on the banks of the Bosphorus, is 141 feet in circumference at the base, extends its branches 45 feet from the trunk, and is believed to be more than 2000 years old. The wood of the *P.*, when young, is yellowish-white; when old, it is brownish, fine grained, takes a high polish, and is esteemed for cabinet-making. A rich alluvial soil and the vicinity of water are most suitable to this tree.

The **NORTH AMERICAN P.**, or **BUTTONWOOD** (*P. occidentalis*), is a very similar tree. It is the largest deciduous tree of the United States, and abounds on the banks of the great rivers of the middle states. Its timber is not very valuable, and is very liable to decay. A tree of this species on the bank of the Thames, in Chelsea Hospital gardens, is 115 feet high, with a trunk five feet in diameter. The name *P.*-tree is commonly given in Scotland to the Sycamore (*Acer pseudo-platanus*), which resembles the true planes in its foliage.

PLANE, a tool used for rendering the surface of wood smooth and level. It consists of an oblong block of wood or metal (the latter has only recently come into use), with an opening through the center; this opening is square on the upper side, and is always large enough to admit the cutting instrument; it diminishes down

Fig. 1.

to a mere slit on the under side, just wide enough to allow the cutting edge of the plane-iron and the shaving of wood which it cuts off to pass through. The form of this opening will be seen at *a*, fig. 1, which represents the section of a common jack-plane. The essential part of the tool is the plane-iron, a piece of steel with a

chisel-shaped edge, and a slot in its center for a large-headed screw to work and to attach to it a strengthening plate. Fig. 2 shows the plane-iron, and fig. 3 the same with the strengthening plate attached; these are shown in their proper position at *bd* in the section fig. 1, and they are held in place by the hard-wood wedge (fig. 4), seen also in the section at *c*. By driving in the wedge, the irons are held very firmly in their place, and they are so adjusted that only the fine sharp chisel-edge of the cutting-tool projects through the slit in the bottom of the body of the plane, so

that when the tool is pushed forward by the force of the hand, the cutting edge pares off all irregularities, until the wood is as smooth as the under surface of the plane. There are many modifications in this tool, which can have its cutting edge and under surface made to almost any contour, so that mouldings of all kinds may be made. The two commonest are the jack-plane for rough work, and the smoothing-plane for finishing off plane surfaces.

PLANING-MACHINES have lately been much in use, by which both wood and metal are planed. In the case of those intended for wood, the cutting instruments are moved forward over the wood by machinery in the same manner as in the hand-plane. The precision and rapidity with which these machines-work have given great facilities for building, as one machine will do as much work as sixty men. The planing-machines used for metal are different in principle. A well-tempered, chisel-edged steel cutter is held in a fixed position, pressing downwards upon the metal plate, which is moved forward by powerful machinery. The action of this movement is, that a groove is ploughed into the metal of the size of the steel cutter; when the metal has traveled its full length, and has made the groove complete, the downward pressure of the tool is removed, and by the action of the double screw which has carried it forward, it is returned, and readjusted for another groove to be formed by the side of the first; and this is repeated until the whole surface of the plate is reduced to the required level. However tedious this process may appear, it offers such facilities for metal working as were previously unknown.

PLANE'TA, the Greek name of the vestment called by the Latins Casula, and in English 'Chasuble,' which is worn by priests in the celebration of mass. The form of this vestment in the modern Roman church, differs both from the ancient form and from that in use in the Greek church. The change appears to date from the 9th c., but has been gradual. A certain modification of the Roman planeta was recently introduced in England under the inspiration of the late Mr. Pugin, the great reviver of Gothic architecture and ecclesiastical costume and decoration. But its use has been only partial even in England.

PLANETA'RUM, a machine much employed by astronomers in the 17th and 18th centuries, and first constructed by Huyghens and Römer, for the purpose of exhibiting clearly the motion of the heavenly bodies in conformity with the Copernican doctrine. The P. exhibited only the orbital motions of the planets about the sun, either in circles or ellipses, and with constant or varying motions, according to the perfection of the machine. It was subsequently supplemented by the combined tellurian and lunarian, which exhibited at one and the same time the motion of the moon about the earth and that of the latter round the sun, with the principal phenomena (such as the succession of day and night, the varying length of each, eclipses, and the motion of the moon's apogee and nodes). The old P. was superseded by the Orrery (q. v.). But the most perfect apparatus of this kind is the P. exhibited by Perini in London in 1880. It occupies a pillared chamber with a hemispherical dome, and displays the solar system with the proper movements of the various members, at proportionate velocities.

PLA'NETOIDS, or A'STEROIDS, the name given to that numerous group of very small planets which are situated in the solar system between Mars and Jupiter. Till the present century they remained undiscovered; but for some years before, their existence had been suspected, mainly owing to the remarkable hiatus in the series of the planetary distances when compared with the law of Bode (q. v.). On the first day of the present century the first of them was detected by Piazzi of Palermo, and his success roused his brother astronomers to search for more planets. Their search was successful, for Olbers (q. v.) discovered two in 1802 and 1807, and Harding one in 1804; but as all researches for

some time subsequent to 1807 were unavailing, astronomers gradually allowed themselves to settle down into the belief that no more planetoids remained to be discovered, when the detection of a fifth by Hencke in 1845, revived the hope of fresh discoveries, and from this period no year (excepting 1846) has passed without adding to the list. The number now known is more than 170. This remarkable success of the astronomers of our time is due to the systematic manner in which the zodiacal belt has been explored, and the place and apparent size of every star of this region distinctly determined; so that the presence of a wandering body can at once be detected.

The magnitudes of these celestial bodies have not been accurately ascertained, but it is certain that they are exceedingly small as compared even with Mercury, the least of the other planets; the diameter of the largest among them being generally believed not to exceed 450 miles, while most of the others are very much smaller than this. They also differ, generally speaking, from the rest of the planets in other respects; their orbits are of greater eccentricity, are inclined to the ecliptic at a greater angle, and are interlaced in a most intricate manner, crossing each other so frequently as to form, when viewed perpendicularly, a kind of network. The consequence of this is, that a planetoid which is nearest the sun at one part of its orbit, is, when at another part of its orbit, further from it than are several of the others and a mutual eclipsing of the sun at different periods by two planetoids must be of very frequent occurrence. Of the planetoids, of which the elements had in 1876 been satisfactorily calculated, Flora has the shortest period of revolution, 1193 days, and Sylvia the longest, 2374 days. The corresponding mean distances from the sun, expressed in parts of the earth's mean distance, are, respectively 2.201 and 3.482. [But it is now known that Hilda has a period of 2868 days and a mean distance of 3.947.] The nearest approach to the sun is made by Phocæa (perihelion distance 1.757). Freia recedes furthest from him (aphelion distance 4.002). Polyhymnia's orbit has the greatest eccentricity, amounting to 0.33998; Lomia's, the least, 0.2176. Massalia's orbit makes a smaller angle—only 41° 7'—with the ecliptic than that of any other planet in the solar system, while the inclination of the orbit of Pallas is no less than 34° 42' 41". After the first two or three of these bodies had been discovered, the opinion was propounded by Olbers that they were but the fragments of some large planet; and this hypothesis received corroboration from the intimate connection which was shown to subsist among them; but of late years it has fallen out of favor with astronomers. Some infer that the P. are best accounted for by the nebular hypothesis.

It has been calculated that the combined mass of all the P. cannot exceed one-fourth of the earth's mass.—The number of P. discovered now amounts to 230; the following is a table of those known in February 1877:

Name.	Date of Discovery.	Discoverer.
1 Ceres	1801, Jan. 1	Piazzi, Palermo.
2 Pallas	1802, Mar. 28	Olbers, Bremen.
3 Juno	1804, Sept. 1	Harding, Bremen,
4 Vesta	1807, Mar. 29	Olbers.
5 Astræa	1845, Dec. 8	Hencke, Driesen (Prussia)
6 Hebe	1847, July 1	Hencke.
7 Iris	" Aug. 13	Hind, London.
8 Flora	" Oct. 18	Hind.
9 Metis	1848, Apr. 25	Graham, Sligo.
10 Hygiea	1849, Apr. 12	De Gasparis, Naplès.
11 Parthenope	1850, May 11	De Gasparis.
12 Victoria	" Sept. 13	Hind.
13 Egeria	" Nov. 2	De Gasparis.
14 Irene	1851, May 19	Hind.
15 Eunomia	" July 29	De Gasparis.
16 Psyche	1852, Mar. 17	De Gasparis.
17 Thetis	" Apr. 17	Luther, Bilk (Düsseldorf).
18 Melpomene	" June 24	Hind.
19 Fortuna	" Aug. 22	Hind.
20 Massalia	" Sept. 19	De Gasparis.
21 Lutetia	" Nov. 15	Goldschmidt, Paris.
22 Calliope	" Nov. 16	Hind.
23 Thalia	" Dec. 15	Hind.
24 Themis	1853, Apr. 5	De Gasparis.
25 Phocæa	" Apr. 7	Chacornac, Marseille.
26 Proserpine	" May 5	Luther.
27 Euterpe	" Nov. 8	Hind.
28 Bellona	1854, Mar. 1	Luther.
29 Amphitrite	" Mar. 1	Marth, London.
30 Urania	" July 22	Hind.
31 Euphrosyne	" Sept. 1	Ferguson, Washington.
32 Pomona	" Oct. 26	Goldschmidt.
33 Polyhymnia	" Oct. 28	Chacornac, Paris.

PLANETS (Gr. *planetes*, 'a wanderer') are those heavenly bodies (including the Earth) which belong to our solar system, and revolve in elliptic orbits round the sun. They are often denominated *primary planets*, to distinguish them from their moons or satellites, which are called *secondary planets*. The name planet is of considerable antiquity and was applied to these dependants of the sun to distinguish them from the myriads of luminous bodies which stud the sky, and which present to the naked eye no indication of change of place (see STARS). The planets at present known are, in the order of their distance from the sun, Mercury, Venus, the Earth, Mars, the Planetoids (q. v.), Jupiter, Saturn, Uranus, and Neptune. Six of these, Mercury, Venus, the Earth (which was not, however, then reckoned a planet), Mars, Jupiter, and Saturn were known to the ancients; Uranus was discovered by Sir William Herschel (q. v.) in 1781; and Neptune, after having its position and elements determined theoretically by Leverrier and Adams, was discovered by M. Challis, and afterwards by Dr. Galle, in 1846. The Planetoids, of which more than 180 are now known, have all been discovered during the present century. Five of the planets, the Earth, Jupiter, Saturn, Uranus, and Neptune, are attended by one or more satellites; Uranus (generally), Neptune, almost the whole of the Planetoids, and all the satellites except the Moon, are invisible to the naked eye. The visible planets can be at once distinguished

from the fixed stars by their clear steady light, while the latter have a sparkling or twinkling appearance. The comparative proximity of the planets may be proved by examining them through a telescope of moderate power, when they appear as round luminous disks, while the fixed stars exhibit no increase of magnitude.

The planets, as observed from the Earth, move sometimes from west to east, sometimes from east to west, and for some time remain stationary at the point where progression ends and retrogression commences. This irregularity in their movements was very puzzling to the ancient astronomers, who invented various hypotheses to account for it. See PROLEMAIC SYSTEM and EPICYCLE. The system of Copernicus, by assuming the sun, and not the earth, as the center of the system, explained with admirable simplicity what seemed before a maze of confusion.

The planetary orbits differ considerably in their degrees of eccentricity, the Planetoids, Mars, and Mercury being most, and the larger planets least eccentric. No two planets move exactly in the same plane, though as a general rule, the planes of the larger planets most nearly coincide with that of the ecliptic. The latter are consequently always to be found within a small strip of the heavens extending on both sides of the ecliptic; while the others have a far wider range, Pallas, one of them, having the angular elevation of its orbit no less than $34^{\circ} 42'$ above the ecliptic. According to Kepler's Laws (q. v.), the nearer a planet is to the sun the shorter is the time of its revolution. The arrangement of the planets in the solar system bears no known relation to their relative size or weight, for though Mercury, Venus, and the Earth follow the same order in size and distance from the sun, yet Mars, which is further from the sun, is much less than either the Earth or Venus, and the Planetoids, which are still further off, are the least of all. Jupiter, which is next in order, is by far the largest, being about 14 times as large as all the others together; and as we proceed further outwards, the planets become smaller and smaller, Saturn being less than Jupiter, Uranus than Saturn, and Neptune than Uranus.

With reference to their distance from the sun, as compared with that of the Earth, the planets are divided into *superior* and *inferior*; Mercury and Venus are consequently the only 'inferior' planets, all the others being 'superior.' The inferior planets must always be on the same side of the Earth as the sun is, and can never be above the horizon of any place (not in a very high latitude) at midnight; they are always invisible at their superior and inferior conjunctions, except when, at the latter, a *transit* (see SUN) takes place. The superior planets are likewise invisible at conjunction, but when in opposition they are seen with the greatest distinctness, being then due south at midnight. The time which elapses from one conjunction to its corresponding conjunction is called the *synodic period* of a planet, and in the case of the inferior planets must always be greater than the true period of revolution.

Mercury, the planet which is nearest the sun, is also, with the exception of the Planetoids, the smallest (being only 3 times the size of the moon), and performs its revolution round the sun in the shortest time. Its greatest elongation is never more than $28^{\circ} 45'$, and consequently it is never above the horizon more than two hours after sunset, or the same time before sunrise; on this account, and from its small apparent size ($5''$ to $12''$), it is seldom distinctly observable by the naked eye. It shines with a peculiarly vivid white or rose-colored light, and exhibits no spots.

Venus, the next in order of distance and period, is to us the most brilliant of all the planets. Its orbit is more nearly a circle than any of the others, and when at its inferior conjunction, it approaches nearer the Earth than any other planet. Its apparent angular dimensions thence vary from $10''$ at the superior, to $70''$ at the inferior conjunction. Its greatest elongation varies from 45° to $47^{\circ} 12'$, and therefore it can never be above the horizon for much more than three hours after sunset, or the same time before sunrise. While moving from the inferior to the superior conjunction, Venus is a *morning star*; and during the other half of its synodic period, an *evening star*. When this planet is at an elongation of 40° , its brilliancy is greatest, far surpassing that of the other planets, and rendering a minute examination through the telescope impossible. At this period it sometimes becomes visible in the daytime, and after sunset is so bright as to throw a distinct shadow. Astronomers have repeatedly attempted to ascertain the nature and characteristics of its surface, but its brightness so dazzles the eyes as to render the correctness of their observations at best doubtful. From the changes in the position of dusky patches on its surface, which have been frequently noticed, it is concluded that it revolves on its axis, and that its equator is inclined to the plane of its orbit at an angle of 75° ; but many astronomers doubt these conclusions. Both Venus and Mercury necessarily exhibit phases like the moon. For *transits* of Venus, see SUN.

The *Earth*, the next planet in order, will be found under its own name; it has a single satellite, the *Moon* (q. v.).

Mars, the first of the superior planets, is much inferior in size

to the two previous, its volume being about $\frac{1}{4}$ th of the Earth's, and, after Mercury, its orbit is much more eccentric than those of the other planets. When it is nearest to the Earth (i. e., in opposition), its apparent angular diameter is $30''$; when furthest from it (i. e., in conjunction), not more than $4''$. Mars revolves on its axis (which is inclined at an angle of $28^{\circ} 27'$) in 24 hours 37 minutes, and its year is 687 days long. In 1877, Hall of Washington discovered that it had two satellites. It shines with a fiery red light, and is a brilliant object in the heavens at midnight when near opposition; when seen through the telescope its surface appears to be covered with irregular blotches, some of them of a reddish, others of a greenish color, while at each pole is a spot of dazzling white. The red spots are surmised to be land; the green, water; while the white spots at the poles are with some reason supposed to be snow, since they decrease when most exposed to the sun, and increase under the contrary circumstances. The Phases (q. v.) of Mars range between full, half, full (in conjunction, if visible), and half.

The *Planetoids*.—After Mars in order come the *Planetoids* (q. v.), formerly but improperly called Asteroids.

Jupiter, the next in order, is the largest of all the planets, its bulk being more than 1400 times that of the Earth, though, from its small density, its mass is only 338 times more. After Venus it is the brightest of the planets and the largest in apparent size, its angular diameter varying from $30''$ to $45''$. When looked at through a telescope, it is seen to be considerably flattened at the poles, owing to its rapid revolution on its own axis; and its surface is crossed in a direction parallel to its equator by three or four distinct and strongly-marked belts, and a few others of a varying nature. Spots also appear and remain for some time on its surface, by means of which its revolution on its axis has been ascertained. This planet is attended by four satellites, which are easily observable through an ordinary telescope, and which have rendered immense service in the determination of longitudes at sea, and of the motion and velocity of light. The satellites, which were discovered by Galileo, were proved by Sir William Herschel to revolve on their own axes in the same time that they revolve round their primary. The smallest is about the same size as our Moon, the others are considerably larger.

Saturn, next in position, is about 785 times larger in volume, though only about 100 times greater in mass than the earth. Its apparent diameter when in opposition is $18''$, and there is a considerable flattening towards the poles. Its surface is traversed by dusky belts much less distinctly marked than those of Jupiter, owing doubtless in great part to its inferior brightness; its general color is a dull white or yellowish, but the shaded portions, when seen distinctly, are of a glaucous color. The most remarkable peculiarity of Saturn is its ring, or series of concentric rings, each one parallel and in the same plane with the others and with the planet's equator; the rings are at present supposed to be three in number, the two outermost are bright like the planet itself, while the innermost is of a purplish color, and is only discernible through a powerful telescope. The rings are not always visible when Saturn is in the 'opposite' half of its orbit, for when the plane of the rings is intermediate between that of the Earth's orbit and of the ecliptic, their dark surface is turned towards us, and when the sun is in their plane only the narrow edge is illuminated; in both of these cases the ring is invisible from the Earth. Its plane being inclined at an angle of 28° to the ecliptic, we see the two surfaces of the ring alternately for periods of 15 years at a time; and at the middle of each period, the rings attain their maximum obliquity to the ecliptic, and are then best seen from the Earth. It is hardly necessary to remark that at the end of each period they become invisible. Saturn has also no less than eight satellites, seven of which revolve round it in orbits little removed from the plane of the ring, while the eighth, which is the second in size, is considerably inclined to it. Two of the satellites were discovered by Herschel in 1787 and 1789, four by Cassini in 1672 and 1684, one by Huyghens in 1655, one by Mr. Lassell in England and Professor Bond in America in 1848. The satellites are all situated outside of the ring, and the largest of them is nearly equal to the planet Mars in size.

Uranus, the next planet in position, was discovered accidentally by the elder Herschel on 13th March 1781, and was named 'the Georgium Sidus' and 'Herschel,' but these names soon fell into disuse. It is about 96 (some astronomers say 82) times greater than the Earth in volume, and 20 (according to others, 15) times in mass; but though so large, its distance is so much greater in proportion that astronomers have been unable to gain much information concerning it. No spots or belts have hitherto been discovered on its surface, and consequently its time of rotation and the position of its axis are unknown. It is attended by a number of satellites, but so minute do these bodies appear, that astronomers hitherto have been unable to agree as to their exact number; Sir William Herschel reckoned six, while other astronomers believe in the existence of four, five, and eight respectively. That there are at least four is without doubt.

Neptune is the next and outermost member of the solar system, and, at a distance of nearly 3000 millions of miles from the center of the system, slowly performs its revolution round the sun, accomplishing the complete circuit in about 165 solar years. It is about 84 times larger than the Earth, but from its extreme remoteness is of almost inappreciable magnitude when seen through an ordinary telescope. It was the disturbance in the motion of Uranus caused by the attractive force of this planet which led Leverrier and Adams to a calculation of its size and position, on the supposition of its existence; and the directions which were given by the former to Dr. Galle of Berlin, specifying its exact position in the heavens, led that astronomer to its discovery on 23d September 1846. Mr. Lassell of Liverpool has discovered that Neptune is attended by one satellite. The satellites of Uranus and Neptune differ from the other planets, primary and secondary, in the direction of their motion, which is from east to west, and in the case of the former, in planes nearly perpendicular to the ecliptic. Both Uranus and Neptune were observed long before the times of Herschel and Leverrier, but they were always supposed to be stars. Uranus is known to have been observed by Flamsteed between 1690 and 1715, and Neptune by Lalande in 1795.

In astronomical tables, almanacs, &c., the planets are for convenience denoted by symbols instead of their names, as follows: Mercury, ☿; Venus, ♀; Earth, ⊕; Mars, ♂; the Planetoids, in the order of their discovery, ♃, ♄, ♅, &c.; Jupiter, ♃; Saturn, ♄; Uranus, ♅; Neptune, ♆; the Sun, ☉; the Moon, ☾.

For a TABLE of the periods, distances, size, density, &c., of the planets, see SOLAR SYSTEM.

PLANT, a living organic being, destitute of any indication of mind or feeling, and sometimes defined as essentially differing from an animal in the want of voluntary motion. Plants are the organisms which form the *vegetable kingdom*; the science which treats of them is Botany (q. v.). Plants of higher organization can never be mistaken for animals, nor animals of higher organization for plants. But there is no regular ascending and descending scale of organisms, from the highest animal to the lowest plant; instead we find a widely-extended base from which the ascent seems to begin at once in both the organic kingdoms, with many ramifications in each; and in the case of the lowest groups of either kingdom, it is sometimes difficult to discern the difference between plants and animals. The difficulty may be owing to our ignorance and incapacity of proper observation.

Something which resembles the voluntary motion of animals is to be seen in some plants, in various phenomena of Irritability (q. v.); and there is even locomotion in the vegetable kingdom wonderfully simulating voluntary locomotion, a provision of nature for the diffusion of some of the lower vegetable organisms; the *Gonidia* (q. v.) of Algae and the *Spermatozoidia* (q. v.) of some other cryptogamous orders moving in a surrounding fluid by means of cilia, so that they have often been mistaken for animalcules. But no motion which can really be deemed voluntary takes place in the vegetable kingdom; and no animal, certainly to be pronounced such, fails to exhibit it—even when there is no power whatever of locomotion—in the prehension of food, or for some of the purposes of life.

The general laws which govern life prevail in plants as in animals. There are organs of nutrition and organs of reproduction; the whole being made up of organs, and every organ destined to maintain the existence either of the individual or of the race. But there is nothing in plants corresponding to the mouth, stomach, and alimentary canal of animals. Nutrition takes place in a different manner; assimilation being effected by a process very unlike that of digestion in animals. There are, however, animals destitute of a mouth, stomach, and alimentary canal; so that the distinction between plants and animals cannot be stated so absolutely in this respect as in respect to voluntary motion; and as there are many plants which have no roots, nutrition by means of roots, although peculiar to the vegetable kingdom, is not its distinguishing characteristic. The nutriment of plants is derived either by their roots from the soil (see ROOT), or through the integuments of their other parts from the air or water in which they live; and all their nutriment is either liquid or gaseous, being taken up in the former case by Endosmosis (q. v.), and in the latter case through Stomata (q. v.). Many plants, and among them the greater number of planerogamous plants, owe their nourishment both to the soil and to the atmosphere, their roots deriving it from the former, and the Leaves (q. v.) of plants that have leaves being the principal organs by which they derive it from the latter. When leaves are wanting, the integument of the parts exposed to the air performs the functions ordinarily assigned to them. Solid matter cannot be appropriated by plants until it has been dissolved in water, or decomposed. See MANURE and SOIL.

The nutriment appropriated by the plant is not assimilated until it has undergone chemical changes, which sometimes take place entirely within the very cell through the integument of which it

has entered, some of the lowest kinds of plants consisting altogether only of a single cell; but which in other plants of higher and more complex organization, depend upon a Circulation of the Sap (q. v.), and a very various action of many different organs, each formed of a multitude of cells. These processes are still very imperfectly understood. By them, not only is the plant nourished, but vegetable products of every kind are elaborated, in which, throughout the wide domains of the vegetable kingdom, there is such wonderful variety, and often great diversity in different parts of the same plant.

Whatever the source from which plants derive their nutriment, no organic substance is appropriated by them; but in order to their use, it must first undergo decomposition. Their food consists wholly of inorganic matter, and the value of organic substances as manures depends not only on the abundance which they contain of the proper elements, but of the readiness with which they undergo decomposition so as to present these elements in the most suitable form; which is not, however, as elements uncombined, but in various combinations with each other. Thus carbon and oxygen enter plants together in the form of carbonic acid, oxygen and hydrogen together in the form of water, hydrogen and nitrogen in the form of ammonia. Carbonic acid absorbed by the leaves from the air is decomposed within the plant, under the influence of light, and particularly of the direct rays of the sun, and its carbon enters into new combinations to form vegetable substances, whilst its oxygen is exhaled again into the atmosphere, which is thus maintained in a state fit for the support both of vegetable and animal life by the opposite and balanced action of animals and plants.

Of the elements which enter into the composition of vegetable substances, Carbon is the most abundant; and, along with it, Oxygen, Hydrogen, and Nitrogen constitute the chief part of every plant. Other elements, both metallic and non-metallic, are found in comparatively small quantity, although some of them are very generally present in plants, as Calcium, Potassium, Sodium, Sulphur, Phosphorus, Silicon, Iron, Aluminium, Magnesium, Chlorine, and Iodine. Among the elements found in plants are also to be enumerated Bromine, Manganese, and Copper, which occur only in minute quantities, and Copper very rarely.

There is no circulation in plants like that of the blood in animals, nor any organ at all analogous to a heart; although there is a constant motion or circulation of their juices, both throughout the whole organism and within individual cells. And although the term *respiration* has been often employed with reference to plants, and particularly to leaves, yet there is not only no action analogous to that of lungs, but no oxygenation of the juices by their being brought into contact with the air; carbonic acid and ammonia—not oxygen—being imbibed from it for nutrition. And there is nothing in the vegetable kingdom having the slightest resemblance to a brain or a nervous system. In the possession of sexual organs, however, there is a wonderful agreement, where it might least have been expected, between plants—or at least all planerogamous plants—and animals. As to this and other important points concerning the life of plants, see VEGETABLE PHYSIOLOGY. See also the article FLOWER, and those on the different organs of which the flower is made up; the articles FRUIT, SEED, SPORE; CELLS, CELLULAR TISSUE, VASCULAR TISSUE; METAMORPHOSIS OF ORGANS; LEAVES; STEM, &c. The great divisions of the vegetable kingdom are noticed in the article BOTANY, in connection with the subject of classification, and in separate articles. The GEOGRAPHICAL DISTRIBUTION OF PLANTS, and the DISEASES OF PLANTS, are noticed under these heads.

Besides the relations of the animal and vegetable kingdoms already noticed in this article, in their joint and balanced action, keeping the constitution of the atmosphere such as is fit both for animal and vegetable life, reference may be here made, in conclusion, to similar relations subsisting in plants and animals as to temperature and as to their mutually providing food for one another. 'It would almost seem as if plants possessed a power of producing cold analogous to that exhibited by animals in producing heat, and of this beneficent arrangement man enjoys the benefit in the luxurious coolness of the fruit which nature lavishes on the tropics' (Sir J. E. Tennent). Flowers indeed produce heat; but the juices of plants are colder than the soil or surrounding atmosphere during the time of active vegetation; and the coolness of groves is owing not only to shade but to the transpiration of moisture by the innumerable leaves.—Inorganic substances are appropriated by plants, as food, and converted by a 'high and mysterious' chemistry into organic substances of many kinds, many of them suitable food for animals, which feed on organic substances alone. But the excrements of animals again furnish food for plants; and when animals die, their bodies undergo a series of changes by decomposition, which terminate in the production of the substances most suitable for the nourishment of plants. There is, moreover, not only this conversion of the same matter into animal and vegetable substances alternately; but

there is also a continual transformation of matter which has remained inorganic throughout long geologic periods into organic substances, and in this some of the lowest kinds of plants are particularly employed, as lichens, which decompose and feed upon the very rocks on which they grow; whilst, on the other hand, the fossil remains of remote periods, are all the products of decomposition, exhibit matter which once formed part of living organisms returned to an inorganic state.

PLANTA'GENET, the surname of the French family of Anjou, which, in 1154, succeeded to the throne of England on the extinction of the Norman dynasty in the male line, and reigned till 1485, when it was supplanted by the family of TUDOR (q. v.). The name P. belonged originally to the House of Anjou, and is said by antiquarians to have been derived from the circumstance of the first count of this house having caused himself to be scourged with branches of broom (*planta-genista*), as a penance for some crime he had committed. On the extinction of the male line of the Norman dynasty in the person of Henry I., the crown of England was claimed by Stephen, count of Blois, the son of Henry's sister Adela, or Adeliza, and by Henry's own daughter Matilda ('the Empress Maud'), then the wife of Geoffrey P., Count of Anjou, for her son Henry Plantagenet. Stephen, by favor of the nobles, was the successful competitor, on the condition that Henry should succeed him; and accordingly on Stephen's death, in 1154, the son of Geoffrey P. ascended the throne of England as Henry II. His sons Richard I. and John succeeded him, and the descendants of the latter in the direct male line—viz., Henry III., Edward I., Edward II., Edward III., and (Edward III.'s eldest son, the Black Prince, having died before his father, leaving an only son, who as) Richard II.—succeeded without interruption. The eldest male line now became extinct, and it was necessary to choose the rightful heir to the throne from among the descendants of Edward III.'s other sons. His second son had died without heirs, but Lionel, Duke of Clarence; John of Gaunt, Duke of Lancaster; and Edmund Langley, Duke of York, his third, fourth, and fifth sons respectively, were still represented by legitimate issue. Of these, Edmund Mortimer, Earl of March, and Anne Mortimer, the wife of Richard, Earl of Cambridge (who was the eldest son and heir of Edmund Langley, Duke of York), the lineal descendants of Lionel of Clarence, possessed the prior claim to the throne; but Edmund was put in prison by Henry IV., the eldest son of John of Gaunt, Duke of Lancaster, who usurped the crown in 1399, and transmitted it to his lineal descendants Henry V. and Henry VI.

By this time Edmund Mortimer had died without heirs, and the descendants of the marriage of his sister Anne (the heiress of Clarence) with Richard, Earl of Cambridge (the heir of York), uniting the claims of the *third* and *fifth* sons, had, through their maternal ancestry, a superior claim to the throne over Henry VI. the Lancastrian monarch, who only represented the *fourth* son of Edward III. Richard Duke of York, the son of Richard of Cambridge and Anne Mortimer, attempted to obtain the crown, but he was taken and executed, leaving to his sons the task of avenging his death, and asserting the claims of the combined house of York and Clarence to the throne, in which they were ably assisted by Richard Neville, Earl of Warwick ('the King-maker'). The result was a long and desolating civil war (1455–1485) between the partisans of York and Lancaster, which is known in history as the 'Wars of the Roses' (the Lancastrians having chosen for their emblem a *red* and the Yorkists a *white* rose), in which more than 100,000 persons perished, and many noble families were either extirpated on the field and the scaffold, or completely ruined. During this dreadful contest in which the Yorkists generally had the advantage, Edward IV. (the eldest son of the Duke of York who had been executed), his son Edward V., and his brother Richard III. (q. v.) successively swayed the sceptre. But Richard's cruel and tyrannical government added new vigor to the reviving Lancastrians, and Henry Tudor (see HENRY VII.), the representative of their claims, defeated the Yorkist tyrant on the field of Bosworth; and then, by his marriage with Elizabeth, the eldest daughter of Edward IV., and the representative of the Yorkist claims, reunited in his family the conflicting pretensions to the throne, which he transmitted in peace to his descendants. See TUDOR; and for the events of this contest, see ROSES, WARS OF THE.

PLANTAGINÆ, or PLANTAGINACEÆ, a natural order of exogenous plants, mostly herbaceous and without stems; the leaves forming rosettes, flat and ribbed, or taper and fleshy; the flowers generally in spikes, and generally hermaphrodite; the calyx 4-parted, persistent; the corolla hypogynous, membranous, persistent, its limb 4-parted; the stamens four, inserted into the corolla, with long filaments; the ovary free, of a single carpel, 1–4 celled; the cells containing one, two, or many ovules; the fruit, a membranous capsule with a lid. The *testa* of the seeds abounds in mucilage, which is easily extracted by boiling water. The order is allied to *Plumbaginæ* and *Primulacæ*. There are

about 120 known species, diffused over all parts of the globe, but most abundant in temperate and cold countries. The most important genus is *Plantago*, the species of which often receive the English name PLANTAIN. Five of this genus are found in the United Kingdom, the chief of which are the following: the GREATER PLANTAIN, or WAYBREAD (*P. major*), one of the most common of British plants; a perennial, with broad ovate stalked leaves and long cylindrical spikes, growing in pastures, waysides, &c. It is very widely diffused over the world. Its seeds

Greater Plantain (*Plantago major*).

are a favorite food of birds, and the gathering of the spikes to feed cage-birds is familiar to every one. The leaves are applied to wounds by the peasantry in many districts. They are said also to be a useful application to ulcers and indolent scrofulous tumors.—The RIBWORT PLANTAIN, or RIBGRASS (*P. lanceolata*), is another very common British plant, forming no small part of the herbage of many meadows and pastures, and sometimes sown by farmers, because its foliage is produced early in the season, and is then acceptable to oxen, sheep, and horses; but deemed most suitable for poor soils, as its spreading leaves occupy too much of the ground, and choke better grasses in rich land. Its leaves are lanceolate, and taper at both ends; its spikes are short, ovate or cylindrical, and placed on long angular stalks. Its seed is acceptable to cage-birds.

This is the plant commonly known as 'bullies,' or 'sodgers,' the striking off the heads (or spikes) of which is such a favorite amusement of children.—The mucilage of the seeds of *Plantago ispaghula* and of *P. psyllium* is much used in India in catarrhs and other complaints; and *P. psyllium*—called FLEAWORT, and its seeds FLEASEED—is cultivated in France for the sake of this mucilage, which is used by paper-stainers in preference to that obtained from linseed, and is also extensively used by muslin manufacturers for stiffening their goods. The plant has a branched spreading stem, and recurved leaves.

PLANTAIN (*Musa Paradisiaca*), a most important food-plant of tropical countries, and one of the largest of herbaceous plants, belongs to the natural order *Musaceæ* (q. v.), and is a native of the East Indies, where numberless varieties of it have been cultivated for thousands of years. It is now diffused over all the tropical and subtropical regions of the globe. It must have been carried to America soon after or during the days of Columbus, for its fruit was a principal article of food there in the first half of the 16th c.; but there is nothing to support the conjecture of Humboldt that there may be different species cultivated under the name of P., and some of them natives of America. The P. is now, however, cultivated to the furthest depths of the primeval American forests, accompanies the Indians in their frequent changes of residence, forms the wealth of many occupiers of land in the vicinity of great towns, where large plantations of it are made, and is a true staff of life to the population of all colors and classes in tropical countries. In many regions it is the principal article of food.

In the genus *Musa* there arise from the midst of the leaves—or apparently from the top of the stem, the sheathing bases of the leaves forming a tree-like false stem—stalks which bear great spikes of flowers, each enclosed in a large bract or spathe; the flowers, and afterwards the fruit, are arranged in clusters or almost in whorls on the stalk; the flowers have a perianth of six

segments, five of which cohere as a tube slit at the back, and the sixth is small and concave; there are six stamens, one or more of them imperfect; the germen is inferior, 3-celled, with two rows of ovules in each cell; the fruit is fleshy, and has many seeds imbedded in its pulp. The name *Musa* is from the Arabic *muz*, a plantain; the *P.* seems to be described by Pliny under the name *pala*, a name probably derived from an eastern root, from which also comes the name *plantain*. The specific name *Paradisaiaca* alludes either to a fancy that the *P.* was the forbidden fruit of Eden, or to a legend that the aprons which our first parents made for themselves were of *P.* leaves.

The stem of the *P.* is usually 15 or 20 feet high, although there are varieties having a stem of only six feet. The leaves are very large, the blade being sometimes ten feet long and three feet broad, undivided, of a beautiful shining green; the midrib strong and fleshy. The fruit is oblong, varying from its usual long shape to an almost spherical one, obscurely angular, eight inches to a foot long in the varieties commonly known by the name *P.*, of which the fruit is usually cooked or prepared in some way in order to be eaten, and very often forms a substitute for bread; whilst the smaller-fruited varieties, of which the fruit is eaten raw, are generally known by the name *Banana* (q. v.); these names, however, being somewhat variously used.

The *P.* is generally propagated by suckers; and a sucker attains maturity in about eight months or a year after being planted. The stem is cut down after fruiting, but the plantation does not require renewal for 15 or 20 years. Plantains ought to be at least ten feet apart in plantations of them, or six feet in single rows around fields or gardens. The *P.* has been sometimes cultivated with success in hothouses.

With the exception of two or three palms, it would not be easy to name, in the whole vegetable kingdom, any plant which is applied to a greater number of uses than the plantain. The fruit is sometimes eaten raw, although more generally—except that of the banana—boiled or roasted, and variously prepared. It is both farinaceous and saccharine. In most of the varieties it has a sweetish taste; in some it is mealy; and in some it is sub-acid or austere. It is as much used before being perfectly ripe as when it is so. In the West Indies the *P.* boiled and beaten in a mortar is a common food of the negroes. Plantains baked in their skins, or fried in slices with butter and powdered over with sugar, are favorite dishes in some tropical countries. They are preserved by drying in the sun or in ovens, and pressed into masses, in which state they keep for years, and furnish a wholesome article of food. The unripe fruit, peeled, sliced, dried, and powdered, is called *P. meal*, and in Guiana *Conquin-tay*; it is whitish with dark-red specks, a fragrance like orris-root, and a taste like wheat-flour; and is made into excellent and nourishing dishes. A good and wholesome starch is obtained from the *P.*, by rasping and washing.—A decoction of the fruit is a common beverage; and a kind of wine is obtained from it by fermentation.—The top of the stalk is a good boiled vegetable.—The leaves are much used for packing, and many other purposes; the fibre of their stalks is used for textile purposes and for cordage; and it is probable that it might be used for paper-making; but hitherto the leaves and stems of plantains have been generally burned or left to rot.

So great is the food produce of the *P.*, that, according to Humboldt's calculation, it is to that of the potato as 44 to 1, and to that of wheat as 133 to 1. The *P.* requires little attention.

The name *P.* is frequently extended to the whole genus *Musa*. Wild species, with austere fruit, are found in many parts of the East. One ascends the Himalayas to an elevation of 6500 feet. A species found in the South Sea Islands (*M. troglodytarum*) is remarkable for bearing its clusters of fruit erect, not pendent like the other species. Its fruit is eatable, as is that of *M. Cavendishii* and of *M. Chinensis*, species or varieties smaller than the common plantain.—The *Musa* which is extensively cultivated in the Philippine Islands for its fibre, *Abaca* or *Manilla Hemp*, is very similar to the common *P.*, but has a green, hard, and austere fruit. It is generally cut when about a year and a half old, before flowering. The outer layers of the stem yield the coarsest fibre; that of the inner is so fine that a garment made of it may be enclosed in the hollow of the hand.—The young stems of *M. Ensete*, the *ENSETTE* of Abyssinia, are used in that country as a boiled esculent.

PLANTAIN-EATER (*Musophaga*), a genus of birds of the family *Musophagidae*, to the whole of which the same English name is often extended. The *Musophagidae* are tropical birds, African and South American, of the order *Insectores* and tribe *Conirostres*, allied to finches, but many of them large, and more like gallinaceous birds than finches. They are birds of beautiful plumage. They have strong thick bills, more or less curved on the top, the cutting edges jagged or finely serrated, so as to render them very efficient instruments for cutting soft vegetable substances, on which they feed, as the plantain and other fruits, and for dividing the succulent stems of plants, which they cut off close

to the ground. They live much among the boughs of trees, and are active and wary birds. The true plantain-eaters (*Musophaga*) have the base of the bill extending upon the forehead; the *TOURACOS* (*Orythya*) have a smaller bill, and the head crested.

PLANTA'TION, a term sometimes applied to places where timber trees have been planted. In that sense, as a general rule, whoever is the owner of the soil, is entitled to the trees which are planted in such soil. When land is let by lease to a tenant, the tenant does not become the owner of the trees, and cannot cut them down. But he is in England and Ireland entitled to reasonable estovers; that is, to cut sufficient wood to repair or build the houses, or make implements of husbandry. The common law of England was very defective in protecting plantations, for it was held that, as the trees were part of the realty, or soil, and nobody could steal the soil, hence nobody could be punished for larceny of trees. But this defect was cured by statute. Whoever cuts, breaks, roots up, or otherwise destroys or damages, with intent to steal, the whole or any part of a tree, sapling, or shrub, if the damage is of the amount of one shilling, may be convicted summarily, before justices of the peace, and fined £5; for a second offence, he may be committed to the house of correction for twelve months or less; and for a third offence, he is guilty of felony, and may be punished as for larceny. So, whoever steals or damages a live fence, may be fined by justices a sum of £5; and for a second offence, may be committed to the house of correction for twelve months. Moreover, if any person is found in possession of a piece of a tree or live fence, and do not give a proper account of his coming into lawful possession of the same, he may be fined £2.—In Scotland, various acts of the Scotch parliament were directed against offences of damaging trees, which are punishable as malicious mischief; the penalty being £10 Scots for each tree less than ten years old, and £20 Scots for each older tree. Tenants may also be fined for such offences. In case of injuries to fences, old Scotch statutes also provide a punishment.

PLANTATION AND PLANTING OF TREES. See **ARBORICULTURE**.

PLANTIGRA'DA, in Cuvier's zoological system, a tribe of *Carnivora* (q. v.) characterized by placing the whole sole of the foot on the ground in walking. The sole is generally destitute of hair. Both fore and hind feet are five-toed in all the plantigrada. The *P.* are generally more or less nocturnal in their mode of life, and their movements are slower and their gait more clumsy than those of the *Digitigrada*. They are also, in general, less carnivorous; many of them feed in part or occasionally on vegetable food. The conformation of their limbs and feet gives them a power of standing erect on their hind feet, which none of the *Digitigrada* naturally possess, and of which advantage is taken in tame bears for the amusement of spectators.

Plantigrade Foot.

PLANTIN, CHRISTOPHE, an eminent printer, was born at St. Avertin, near Tours, in 1514, and set up a printing establishment at Antwerp in 1550, which soon became the greatest and most celebrated of the time. He had often twenty presses or more in active operation. Guicciardini mentions his printing-establishment as the finest ornament of the city of Antwerp, and as one of the wonders of Europe, and the learned agreed in regarding him as the first printer of his time, although he was the contemporary of Aldus and Estienne (Stephens); but this is true only as regards the number of works which issued from his establishment, and the beauty of their typography; for the services which the others have rendered to classic literature are far beyond those of Plantin.

P. was nevertheless himself a man of varied, though probably not very profound learning. He superintended the publication of works in several languages, and was extremely careful of their accuracy, employing able and learned correctors of the press, whom he remunerated liberally, and publicly offering rewards for the discovery of errors. The most noted of all his publications is the *Biblia Polyglotta* (8 vols. 1569–1572), which was printed under the personal superintendence of Arias Montanus, the court chaplain of Philip II. of Spain, and towards which, Philip gave 6000 ducats for the purchase of paper. But the oldest book known to have proceeded from the press of *P.* is the *Institution d'une Fille de Noble Maison, traduite de Langue Toscane en François*, by Jean Beller (Ant. 1555). *P.* died at Antwerp in 1589. He had set up printing-establishments in Leyden and Paris, and these, with that in Antwerp, were carried on by the husbands of his three daughters.

PLANTS, in point of law, when put in a garden or other ground let to a tenant, belong to the landlord, and not to the tenant, for they become part of the soil. Hence, a tenant cannot

dig them up and remove them, at the termination of his lease. This right of the landlord, however, is seldom enforced with much strictness, partly because the tenant may alter and remove the plants at discretion during his lease, and thus can evade the rule of law. In the case of nursery-grounds, however, the above rule does not apply, as between landlord and tenant, for the plants are considered the stock-in-trade of the nurseryman, who puts them in the ground, not with a view to let them grow permanently, but as a convenient mode of keeping them for sale. Hence, at the termination of his lease, the tenant can remove them all.

PLANU'DÉS, MAXIMUS. See ANTHOLOGY.

PLASENCIA, an ancient and much-decayed, but most picturesque town of Spain, in Estremadura, 48 miles north-north-east of Cáceres, stands on a steep hill, with beautiful and fertile valleys, extending on the north-west and south-east sides. It is almost wholly girdled by the clear waters of the Jerte; and the surrounding scenery, embracing city, castle, river, rock, and mountain, and over-arched by a sunny and unclouded sky, is remarkably beautiful. The city contains the picturesque remains of an ancient castle, and is surrounded by crumbling walls, surmounted by 68 towers, and pierced by six gates. Water is brought to the town by an aqueduct of 80 arches. There are seven Gothic churches, and episcopal and several other palaces, and the cathedral, an ornate Gothic edifice, begun in 1498, and some portions of which are still unfinished, while others have been altered and disfigured. The cathedral contains many noble tombs, with effigies. P., once a flourishing and important city, was founded in 1190. It now carries on some minor manufactures of cotton, woollen, and hempen fabrics, and of hats and leather. Pop. (1877) 7090.

PLASMA, a silicious mineral, a variety of quartz or chalcedony, of a dark-green color, black when unpolished and seen by reflected light, but very translucent when held between the eye and the light. It is very nearly allied to hellotrope or bloodstone, but has no red spots, is more translucent, and is not susceptible of so brilliant a polish. It is never found crystallized. It is a rare mineral, and the finest specimens are brought from India and China. It was highly prized by the ancient Romans, who wrought it into ornaments of various kinds; and very fine engraved specimens have been found among the ruins of ancient Rome. The ancients are said to have obtained their plasma from Mount Olympus, in Asia Minor. The name plasma is supposed to be identical with the Greek *prason*, a leek, the *r* having passed into *l*.

PLASSEY (*Palásí*), a battlefield on the Bhágirathi River, 96 miles north of Calcutta. The river has now eaten away the scene of the struggle. P. is celebrated in the history of India for the great victory gained by Clive (q. v.) over Suraja Dowlah, subahdar of Bengal, 23d June 1757, a victory which really laid the foundation of British supremacy in India. The British force at the battle of P. consisted of 1000 British troops and 2000 sepoys. The subahdar's force consisted of 15,000 cavalry and 35,000 infantry, with 40 French artillerymen, and 50 large cannon.

PLASTER OF PARIS. See GYPSUM.

PLASTERING, the art of covering walls, partitions, ceilings, &c., with a composition of lime mixed with sand and hair. It is usually done in three coats. The first coat is the solid foundation on which the rest is placed; it is therefore of a good thickness, and is hatched or crossed with lines, so as to give a bond for the next coat. The first coat is allowed to dry thoroughly; then the second coat is floated over the first, and rubbed well in with a flat board, about 12 inches square, so as to bring it all to a fair and equal surface (in Scotland this is called the 'straightening'); and before the second coat has thoroughly dried, the third or finishing coat is applied in finer materials, and in a more liquid state. In the case of ceiling cornices, mouldings, &c., plaster of Paris or stucco is generally used. This sets or hardens more rapidly than lime, and has a finer and whiter surface. Ornaments (called enrichments) are generally composed of plaster of Paris, and cast in moulds. They are then set in their places after the cornice has been made, or run.

PLASTERS are a class of medicinal agents which are employed externally with various objects. They are solid and tenacious compounds, adhesive at the ordinary temperature of the body, and owing their consistency—1. To the chemical combination of oxide of lead, with one or more fatty acids; or, 2, to a due admixture of wax, or fat, and resin; or, 3, to the chemical action of the component parts of the plaster on each other. Strictly speaking, the term *Plaster* should be restricted to the first class of compounds; viz., to combination of oxide of lead with fatty acids. In the British Pharmacopœia, there are directions for making 12 plasters, viz., ammoniac and mercury plaster, Belladonna plaster, cantharides plaster, chalybeate plaster, galbanum plaster, litharge (or lead) plaster, mercurial plaster,

opium plaster, pitch plaster, resin plaster, soap plaster, and warm plaster.

The litharge (or lead) plaster, directly or indirectly enters into the composition of all the twelve official plasters, excepting those of ammoniac and mercury, cantharides, and pitch. *Lead Plaster*, which is usually sold under the name of *Diachylon*, in combination with resin, constitutes the ordinary *adhesive plaster*. The best plaster of this kind for strapping is composed of a mixture of six drachms of resin with a pound of lead plaster. The *cantharides plaster*, and the *ammoniac and mercury plaster*, are examples of the second and third varieties.

Plasters are generally kept in rolls; and when they are to be used, they are melted at a temperature of not more than 212°, and spread on soft leather. They are employed to answer two distinct indications, namely, to act *mechanically*, as by affording artificial support to weak muscular structures, by preventing threatened or tedious excoriations, by protecting parts already excoriated from the action of the air, &c.; and to act *medicinally* as stimulant, discutient, alterative, anodyne, &c.

PLATA, LA. See ARGENTINE REPUBLIC.

PLATA, RIO DE LA, a wide estuary of South America, between Uruguay on the north and the Argentine Confederation on the south, forms the mouth of the Parana (q. v.) and the Uruguay (q. v.). It is 200 miles long, 29 miles broad at Buenos Ayres, and 140 miles broad at its mouth, between Maldonado and Cape San Antonio. At its mouth it is, on an average, only about 10 fathoms deep; at Monte Video it is only 8 fathoms; and at Buenos Ayres about 16 feet deep. Some conception of the vast volume of water which this estuary carries to the Atlantic may be had when it is remembered that with its affluents it drains an area of 1,250,000 square miles. The strong and irregular currents, and the sudden tempests of the La P., render its navigation extremely dangerous. It is estimated that through this estuary about one-fourth of the produce of South America is brought to market. For the navigation of its affluents, see PARAGUAY, PARANA, and URUGUAY.

PLATEÆA, or PLATÆE, a city in the western part of Bœotia, on the borders of Attica, at the foot of Mount Cithæron. It was about 6½ miles from Thebes. In 480 B.C., it was destroyed by the Persians, because the inhabitants had taken part with Athens in the battle of Marathon; but in the following year it was the scene of the glorious victory won by the Lacedæmonian Greeks, under Pausanias and Aristides, over the Persian hordes commanded by Mardonius—a victory that finally delivered Greece from the threatened yoke of the invader. In the third year of the Peloponnesian war (429 B.C.), it was attacked by a Theban-Lacedæmonian force—for the Plateæans were firm friends of Athens—and heroically defended itself for more than two years, until it was starved into surrender. The little garrison of about 200 men were put to the sword, and the city was razed to the ground. Such of the Plateæans as escaped were hospitably received at Athens. By the treaty of Antalcidas (387 B.C.), their children were allowed to go back again, and rebuild their city, after an exile of 40 years; but they were again driven out by their implacable enemies, the Thebans; and half a century elapsed before the victory of Philip of Macedon at Chæroneia enabled the Plateæans to finally return to their homes. After this, the city remained inhabited, probably till the latest days of the empire. It is mentioned in the 6th c. A.D. Some ruins of P. are still visible near the village of Kokhla.

PLATALEA. See SPOONBILL.

PLAT-BAND, in Architecture, a flat fascia or band, with less projection than breadth.

PLATE, in Heraldry, a Roundle (q. v.) argent. It is represented flat, and in the heraldry of Scotland is known as a *Bezant* argent.

PLATE-MARKS are legal impressions made on articles of gold or silver at the various assay offices, for the purpose of indicating the true value of the metal of which the articles are made. The marks are a series of symbols, which are embossed in a line of about three-quarters of an inch in length, and usually on every separate piece of which an article is composed. These symbols are—1. The maker's own mark or initials. 2. The standard or assay mark; viz., for gold, a crown, and figures denoting the number of carats fine. This means that pure gold is reckoned at 24 carats, and every part of alloy added reduces that standard number (see CARAT); so that if a piece of gold-plate or jewelry is marked with a crown and 18, it indicates that it consists of 18 parts of pure gold, and 6 parts of some other metal alloyed with it. Gold of nine carats is now legal, but as it is marked by the assay office, there can be no deception, if the public understand the plate marks. If not, they may pay for pure gold, relying upon the hall-mark, when they only receive about a third part gold. For Silver—England, a lion passant; Ireland, a harp crowned; Edinburgh, a thistle; Glasgow, a lion rampant. 3. The hall-mark of the district office—London, a leopard's head crowned; York, three lions and a cross; Exeter, a castle with two wings;

Chester, three wheat-sheaves or a dagger; Newcastle, three castles; Birmingham, an anchor; Sheffield, a crown; Edtuburgh, a castle and lion; Glasgow, a tree, salmon, and ring; Dublin, the figure of Hibernia. 4. The duty-mark, indicating the payment of duty, viz., the head of the reigning sovereign. 5. Each office has also its alphabetical date-mark. In London, the assay year, which commences on the 30th May, is indicated by one of the first twenty letters of the alphabet.

The Goldsmiths' Company of London have marked thus :

From 1716 to 1756, Roman Capital Letters.

" 1756 " 1776, Roman Small Letters.

" 1776 " 1796, Old English Letters.

" 1796 " 1816, Roman Capital Letters A to U.

" 1816 " 1836, Roman Small Letters a to u.

" 1836 " 1856, Old English Letters A to U.

" 1856 " 1876, Small Black Letters a to u.

" 1876 onwards, Roman Capitals, distinguished from former series by shape of shield on which they are imprinted.

PLATE-POWDER, a composition used for cleaning gold and silver plate and plated articles. It is also called *Rouge-powder* (see *ROUGE*). It is made by levigating rouge with three times its weight of prepared chalk, until they are thoroughly mixed into an almost impalpable powder. Sometimes Putty-powder (q. v.) is used instead of rouge, and a little rose-pink added to color it. A plate-powder is also sometimes made by levigating quicksilver with twelve times its weight of prepared chalk, until it is thoroughly incorporated, and forms a gray powder. It puts a remarkable brilliancy on silver-plate, but is very injurious to it.

PLATING signifies the covering of an inferior metal with one of the precious metals, the object being to give the appearance of silver or gold to articles chiefly intended for table use. At present the articles are generally made of German silver, or some of the similar white-metal alloys; but formerly, copper, or an alloy of that metal with brass, was used; the disadvantage of which was that, as the coating of silver wore off, the red color of the copper became disagreeably apparent through the thin covering of silver. Gold is rarely plated on any other metal than silver, except for purposes of deception. Previous to the introduction of electro-plating, the method generally pursued was that which has acquired the name of *Sheffield-plating*, from the large extent to which it was carried on in that town. It consists in soldering on to one or both sides of an ingot of the baser metal, a thin plate of silver. The ingot is always of an oblong shape, and is most carefully prepared on the surfaces which are to receive the silver, so

that nothing shall prevent the complete union of the two. The shape and relative proportions of the ingot, and its plating of silver, are seen in the figure: *aa* is the silver on the upper and lower surfaces, for double-plated goods; *b*, the body of the ingot, of copper or white-metal alloy. The soldering is a process requiring much care and nicety: the plates of silver are thinly coated with a concentrated solution of borax, and are then applied to the prepared surfaces of the ingot, to which they are firmly bound with iron wire, and then placed in the *plating-furnace*, and subjected to a strong heat. This furnace is so arranged that the interior can be constantly watched, and when the proper temperature is attained, the workman knows the exact instant to withdraw it.

The act of soldering is almost instantaneous, and fusion would immediately follow, if the ingot was not quickly withdrawn. When cooled, the wire is taken off, and the ingot is taken to the rolling-mill, where it is passed backwards and forwards, of course with the silver above and below, until it is rolled out into a sheet of the exact thickness required. However thin it may be made, it is found that the relative thickness between the ingot and its layers of silver is always the same. As usual in all cases of rolling or striking metal, annealing from time to time is necessary, to remove the brittleness which these operations cause.

This method does not admit of the manufacture of any portions such as ornamental moulded borders, &c.; these had therefore to be formed separately of copper, and were coated by the process called *Silvering* (q. v.). Now, however, it is found better to make them of silver rolled thin, and fill them inside with lead, to give them solidity; by this plan is avoided the annoyance of the silver rubbing off, and exposing the copper. Sheffield-plating is still made extensively, but the manufacture is rapidly declining in presence of the newer art of electro-plating. See *GALVANISM*.

Within a very recent period, and since the subject of electro-plating was treated under the article *GALVANISM*, some very remarkable applications of the process have been discovered; for

instance, it is no longer confined to the deposit of silver and gold; aluminium, silicium, titanium, tungsten, molybdenum, tin, cadmium, lead, bismuth, palladium, rhodium, iridium, and the alloys brass and bronze, are all now deposited under patent processes. Of all these, by far the most important is the deposit of the alloys, and a very large trade has sprung up in manufactures of iron coated with brass. The importance of being able to cover a metal so cheap, yet so easily corroded as cast iron, with so ornamental an alloy as brass or bronze, can hardly be overrated. Consequently the process is carried on very extensively and satisfactorily.

PLA'TINUM (Symb. Pt. equiv. 99—new system, 198—sp. gr. 21.5) is one of the 'noble metals,' which may be obtained in more forms than one. It is only found in the native state, usually occurring in small glistening granules of a steel-gray color, which always contain an admixture, in varying proportions, of several metals, most of which are rarely found except in association with platinum. Sometimes, however, it is found in masses of the size of a pigeon's egg, and pieces weighing ten or even twenty pounds have occasionally been found. The following table shows the composition of crude platinum ore as obtained from different parts of the globe. The analyses were conducted by Messrs. Deville and Debray.

	Columbia.	Californi- a.	Oregon.	Spain.	Australia.	Russia.
Platinum	60.00	79.85	11.45	45.70	59.80	77.50
Iridium	1.55	4.20	0.40	0.95	2.20	1.45
Rhodium	2.50	0.65	0.65	2.65	1.60	2.80
Palladium	1.00	1.95	0.15	0.85	1.50	0.85
Gold	1.50	0.35	0.35	3.15	2.40	2.15
Copper	0.65	0.75	2.15	1.05	1.10	
Iron	7.20	4.45	4.30	6.80	4.30	9.60
Osmide of Iridium	1.40	4.95	37.30	9.85	25.00	2.35
Sand	4.35	2.60	3.00	35.95	1.20	1.00
Osmium and loss.		0.05		0.05	0.80	2.30

Ruthenium is also almost always present, and in the above analyses is probably included with the iridium, which it closely resembles.

There are two modes of obtaining platinum in the form of ingots from the ore, both of which require notice. The method which has been universally employed, till within the last five years, was that discovered by Wollaston, the leading steps of which were as follows: After the removal of the metals associated with the platinum, by the successive action of nitric and hydrochloric acids, the platinum itself is dissolved in aqua regia, from which it is precipitated by a solution of sal ammoniac in the form of a sparingly soluble double salt, the chloride of ammonium and platinum, represented by the formula $H_2NCl.PtCl_4$. This salt is washed and heated to redness, by which means the chlorine and ammonia are expelled, leaving the metal in the form of a gray, spongy, soft mass, known to chemists as *spongy platinum*. In this form, it is very finely powdered under water, is next shaped by intense pressure into a mass, and is then exposed to an intense heat in a wind-furnace, the ingot being formed by hammering it upon its two ends. (If hammered on its sides, it splits). This heating and forging must be repeated till the metal becomes homogeneous and ductile.

Deville and Debray have introduced an entirely new method for the extraction of platinum from its ores. They first form a fusible alloy of this metal with lead, by exposing the platinum ore—2 cwt. being used in a single experiment, with equal weights of galena and litharge gradually added, and a little glass to act as a flux—to full redness in a reverberatory furnace lined with clay. The sulphur of the galena is oxidized and expelled, and the liquid alloy of lead and platinum is allowed to rest for some time, to allow the osmide of iridium, which is not affected by the preceding operations, to sink to the bottom. The upper portions of the alloy are then decanted, and cast into ingot-moulds, which are submitted to cupellation; and the metallic platinum which is left after the cupellation is melted and refined in a furnace of lime—which is employed in consequence of its being a very bad conductor of heat—by means of the oxyhydrogen blowpipe. The platinum obtained in this manner is nearly pure, and very ductile and malleable. For details regarding this process, which has been patented both in France and in this country, the reader is referred to the memoir, 'On Platinum and the Metals which accompany it,' in the *Annales de Chimie et de Physique* for August 1859.

Platinum as obtained by either of the above processes, exhibits a bluish-white metallic lustre; it is exceedingly malleable and ductile, and is very infusible, melting only before the oxyhydrogen blow-pipe, or in a very powerful blast-furnace, such as that used by Deville and Debray. It expands less by heat than any other metal, and is usually regarded as the heaviest form of matter yet known; but, according to Deville and Debray, osmium and iridium are about equally dense. It is unaffected by at-

mospheric action, and does not undergo oxidation in the air at even the highest temperatures. It is not acted on by nitric hydrochloric, sulphuric, or hydrofluoric acid, or in short, by any single acid; but in aqua regia it slowly dissolves, and forms a soluble bichloride. In consequence of its power of resisting the action of acids, it is of great service in experimental and manufacturing chemical processes, platinum spatulas, capsules, crucibles, &c., being employed in every laboratory; while platinum stills, weighing sometimes as much as one thousand ounces, are frequently used for concentrating oil of vitriol. Platinum is, however, corroded if heated with the alkalis or alkaline earths, and especially with a mixture of nitrate of potash and hydrated potash, an oxide being formed which combines with the alkaline bases.

The form of the metal known as *spongy platinum* has been already noticed. The metal may, however, be obtained in a state of subdivision much finer than that in which it is left on heating the double chloride of platinum and ammonium—namely, in the state known as *Platinum Black*. In this form it resembles soot. It may be prepared in various ways, of which one of the simplest is to boil a solution of bichloride of platinum, to which an excess of carbonate of soda and a quantity of sugar have been added, until the precipitate formed after a little time becomes perfectly black, and the supernatant liquid colorless. The black powder is then collected on a filter, washed, and dried by a gentle heat.

In its finely comminuted state, either as spongy platinum or platinum black, it possesses a remarkable power of condensing and absorbing gases, one volume of platinum black being able to absorb more than 100 volumes of oxygen. This absorption appears to be accompanied by a conversion of some or all of the oxygen into the modification known as Ozone (q. v.), since the metal becomes capable of exerting the most energetic oxidizing action, even at ordinary temperatures. For example, it can cause the combustion of a jet of hydrogen, can oxidize sulphurous acid into sulphuric acid, ammonia into nitric acid, and alcohol into acetic acid, the rise of temperature in the last case being often sufficiently great to cause inflammation. Platinum in the compact form, as foil or wire, possesses similar powers, but in a far lower degree.

Platinum may be easily alloyed with most of the metals, the alloys being in general much more fusible than pure platinum. Hence care must be taken not to heat the oxides of metals of easy reduction, such as lead and bismuth, in platinum crucibles, as, if any reduction took place, the crucible would be destroyed by the fusion of the resulting alloy. An alloy of platinum, iridium, and rhodium is found, by the investigations of Deville and Debray, to be harder, and capable of resisting a higher temperature than the pure metal; and hence is admirably adapted for the formation of crucibles, &c.

There are two *oxides* of platinum, a protoxide, PtO , and a binoxide, PtO_2 , neither of which can be formed by the direct union of the elements. Excepting that the change which platinum vessels undergo when containing the caustic alkalis, &c. and exposed to a red heat, is due to the formation of a superficial layer of oxide (probably binoxide), these compounds are of little interest. The *sulphides* and *chlorides* correspond in number and composition to the oxides. Of these compounds, the bichloride (PtCl_2) alone requires notice. It is formed by dissolving platinum in aqua regia, and evaporating the solution to dryness; and it is obtained as a deliquescent, reddish-brown mass, which forms an orange-colored solution in water, from which, on evaporation, it crystallizes in prisms. It is also freely soluble in alcohol and ether. A solution of this salt is much used for the recognition and determination of potash and ammonia.

By the action of ammonia on protochloride of platinum (which is obtained by heating a solution of the bichloride to a temperature of 450°), several remarkable compounds are formed, which possess strong basic characters, and are of great interest in a theoretical point of view, such as Platamine (PtH_2NO), Platinamine ($\text{PtH}_2\text{N}_2\text{O}_2$), &c.

PLATO, who, along with Aristotle, represents to modern Europe the whole compass of Greek speculation, was born at Athens in the year 429 B.C., shortly after the commencement of the Peloponnesian war, and the same year in which Pericles died. He was of a good family—being connected, on the mother's side, with Solon; and on the father's side, with Codrus, one of the ancient kings of Athens. He received a good education, according to the common practice of the Greeks, in music, gymnastics, and literature. His rich and gorgeous imagination is said at first to have essayed its powers in poetry; but when about 20 years of age, having become acquainted with Socrates, he threw all his verses into the fire, and consecrated his great intellect to philosophy. When he was 20 years old, the political troubles, of which the death of Socrates was only one terrible symptom, forced him to leave Athens for a season, and he resided at Megara, with Euclid, the founder of the Megaric sect. The disturbed state of his native

country, doubtless, also was one cause of the frequent travels which he is reported to have made. Of these, his three visits to Sicily, during the time of the elder and younger Dionysius, are the most celebrated and the best authenticated. That he visited Italy, is extremely probable; at all events, he was most closely connected with Archytas and the Pythagorean philosophers; though, as Aristotle (*Metaph.* i. 6) justly remarks, he borrowed from Heraclitus as well as from Pythagoras, and put a stamp of freshness and originality on all that he borrowed.

After returning from his first visit to Sicily, being then in his fortieth year, he commenced teaching philosophy publicly, in the *Academeia*, a pleasant garden in the most beautiful suburb of Athens, and there gathered around him a large school of distinguished followers, who maintained a regular succession after his death, under the name of the Philosophers of the Academy. He lived to the age of 82; was never married; and must have possessed some independent property, as he expresses himself strongly against teaching philosophy for fees, and we nowhere read of his having held any public office from which he could have derived emolument. Such are the few reliable facts known as to the life of Plato.

The principles of his philosophy are happily better known; for all his great works have been preserved, and have always been extensively read wherever the Greek language was known. The only danger to which the students of his philosophy have been exposed is the confusion of the doctrines distinctly taught by him with the exaggeration of these as afterwards worked out by the Neo-Platonists of Alexandria; but this is a danger which the exact critical scholarship of modern times has put out of the way for all persons who exercise common precaution in the acquisition of knowledge. The distinctive character of the Platonic philosophy is expressed by the word idealism, as opposed to realism, materialism, or sensationalism, using these words in their most general and least technical sense, the capacity of forming and using ideas being taken as an essential virtue or quality of mind, as contrasted with matter; of thought as contrasted with sensation; of the internal forces of individuals and of the universe, as contrasted with the external forms by which these forces are manifested.

As such, the ideal philosophy stands generally opposed to that kind of mental action which draws its stores principally from without, and is not strongly determined to mould the materials thus received by any type of thought or hue of emotion derived from within. In other words, the philosophy of P. is essentially a poetical and an artistic philosophy; for poetry, painting, and music all grow out of idealism, or those lofty inborn conceptions by which genius is distinguished from talent. It is also, at the same time, a scientific philosophy, for the purest science, as mathematics—on which P. is well known to have placed the highest value—is a science of mere ideas or forms conditioned by the intellect which deduces their laws; and, above all, it is essentially a moral and a theological philosophy, for practice or action, is the highest aim of man, and morality is the ideal of action; and God, as cause of all, is the ideal of ideals, the supreme power, virtue, and excellence to which all contemplation recurs, and from which all action and original energy proceed. The distinctive excellence of the Platonic philosophy is identical with its distinctive character, and consists in that grand union of abstract thought, imaginative decoration, emotional purity, and noble activity, which is the model of a complete and richly endowed humanity. The poetical element in P., so wonderfully combined with the analytical, shows itself not only in those gorgeous myths which form the peroration of some of his profoundest dialogues, but in that very dialogic form itself, of which the situation is often extremely dramatic; though this form of philosophic discussion perhaps owes its existence more to the lively temper and out-of-door habits of the Greeks, than to the special dramatic talent of Plato.

On the other hand, the defects of the Platonic philosophy arise from its essential one-sidedness, as a polemical assertion of the rights of thought against the claims of the mere senses, of the stability of the eternal type against the constant change that characterizes the ephemeral form. In his zeal to submit all that is external to the imperatorial power of internal conception, the philosopher of ideas is apt to forget the obstinate and unpliant nature of that external world which he would regulate, and after projecting a grand new scheme of society, according to what appears a perfect model, shows like the architect who, after drawing out the model of a marble temple, finds he has only bricks to build it with. For this reason, extremely practical men, and those who are compelled to reason chiefly by an extensive induction from external facts, have ever felt an instinctive aversion to the Platonic philosophy; and P. himself, by some of the strange and startling conclusions, in matters of social science, to which his ideal philosophy led, has, it must be confessed, put into the hands of his adversaries the most efficient weapons by which his ideal system may be combated.

The starting-point of the Platonic philosophy, as, indeed, it must be of all philosophy, properly so called, is the theory of knowledge. This is set forth in the *Theaetetus*, the *Sophistes*, and the *Parmenides*; and in the *Cratylus*, the foundations are laid for a science of language, as the necessary product of a creature energizing by ideas. The Platonic theory of knowledge, as developed in the *Theaetetus*, will be most readily understood by imagining the very reverse of that which is vulgarly attributed to Locke; viz., by drawing a strong and well-marked line between the province of thought and that of sensation in the production of ideas, and taking care that, in the process of forming conceptions, the mind shall always stand out as the dominant factor. In other words, the hackneyed simile of the sheet of blank paper, applied to the mind by extreme sensational philosophers, must either be thrown away altogether or inverted; the more active part of the operation must always be assigned to the mind. The formation of knowledge, according to P., may be looked on as the gradual and systematic elimination of the accidental and fleeting in the phenomenon from the necessary and permanent; and the process by which the mind performs this elimination—and it can be performed only by mind—is called *Dialectics*. This word, from *dialégomai*, originally signifies only conversational discussion; thence, that discussion conducted in such scientific fashion as to lead to reliable results, i. e., strictly logical.

The product of dialectics is ideas, and these ideas being the *éidé*, forms or types of things which are common to all the individuals of a species, all the species of a genus, all the genera of a family, and all the families of a class, generate classification—that is, knowledge of the permanent in phenomena—and definition, which is merely the articulate verbal expression of this permanency. The construction of the confused results of observation into the orderly array of clear conceptions, by a sort of cross-examination of the phenomena, performed by minds impassioned for truth, is exhibited as the great characteristic of the teaching of Socrates, in the *Memorabilia* of Xenophon. In the dialogues of P., the same purification of the reason, so to speak, from the clouds of indistinct sensuousness, is exhibited on a higher platform, and with more comprehensive results. For between Socrates and P., notwithstanding a deep internal identity, there was this striking difference in outward attitude—that the one used logic as a practical instrument in the hands of a great social missionary and preacher of virtue; while the other used it as the architect of a great intellectual system of the universe, first and chiefly for his own time and his own place, but, as the event has proved, in some fashion also for all times and all places.

We should err greatly, however, if we looked on P. as a man of mere speculation, and a writer of metaphysical books, like certain German professors. Neither P. nor any of the great Greeks looked on their intellectual exercises and recreations as an end to themselves. With them, philosophy did not mean mere knowledge or mere speculation, but it meant wisdom, and wisdom meant wise action, and wise action meant virtue. The philosophy of P., therefore, with all its transcendental flights, of which we hear so much, was essentially a practical philosophy; all his discussions on the theory of knowledge and the nature of ideas are undertaken mainly that a system of eternal divine types, as the only reliable knowledge, may serve as a foundation for a virtuous life, as the only consistent course of action. Virtue, with Socrates and P., is only practical reason. As in the Proverbs of Solomon, all vice is folly, so in the philosophy of P., the imperial virtue is *phronesis*—i. e., 'wisdom' or practical 'insight.' The other two great Greek and Platonic virtues—*sophrosyne*, 'moderation' or 'soundmindedness,' and *dikaíosyne*, 'justice,' or the assigning to every act and every function its proper place—are equally exemplifications of a reasonable order applied to action—such an order as alone and everywhere testifies the presence of mind. The theory of morals as worked out from such principles is, of course, as certain as the necessary laws of the reason which it expresses; and, accordingly, the Platonic morality, like the Christian, is of that high order which admits of no compromise with ephemeral prejudice or local usage.

The contrast between the low moral standard of local respectability and that which is congruous with the universal laws of pure reason, stands out as strikingly in Plato, as the morality of the Sermon on the Mount in the Gospels does against the morality of the Scribes and Pharisees. Splendid passages to this effect occur in various parts of P.'s writings, particularly in the *Republic* and the *Gorgias*. In perfect harmony with the Platonic theory of noble action, is his doctrine with regard to pure emotion and elevated passion. Love with P. is a transcendental admiration of excellence—an admiration of which the soul is capable by its own high origination and the germs of godlike excellence, which are implanted into it from above. The philosophy of love is set forth with imaginative grandeur in the *Phaedrus*, and with rich dramatic variety in the *Banquet*, of which dialogue there is an English translation by Shelly. The philosophy of beauty and the theory of pleasure are set forth with great analytic acuteness in

the *Philebus*. With P., the foundation of beauty is a reasonable order, addressed to the imagination through the senses—i. e., symmetry in form, and harmony in sounds, the principles of which are as certain as the laws of logic, mathematics, and morals—all equally necessary products of eternal intellect, acting by the creation and by the comprehension of well-ordered forms, and well-harmonized forces, in rich and various play through the living frame of the universe; and the ultimate ground of this lofty and coherent doctrine of intellectual, moral, and æsthetical harmonies lies with P., where alone it can lie, in the unity of a supreme, reasonable, self-existent intelligence, whom we call God, the fountain of all force, and the creator of all order in the universe; the sum of whose most exalted attributes, and the substantial essence of whose perfection may, as contrasted with our finite and partial aspects of things, be expressed by the simple term to *agathón*—the GOOD.

From this supreme and all-excellent intelligence, human souls are off-shoots, emanations, or sparks, in such a fashion, that they partake essentially of the essential nature of the source from which they proceed, and accordingly possess unity as their most characteristic quality, attest their presence everywhere by a unifying force which acts by impressing a type on whatever materials are submitted to it, and is filled with a native joy in the perception of such types, the product of the same divine principle of unity, wheresoever presented. The undivided unity and unifying force which we call the soul is immortal, being from its nature altogether unaffected by the changes of decay and dissolution to which the complex structure of the material human body is exposed. The doctrine of the immortality of the soul is most fully set forth in the *Phædo*, a dialogue which combines with the abstract philosophical discussion, a graphic narrative of the last hours of Socrates, which, for simple pathos and unaffected dignity, is unsurpassed by any human composition.

The most complete and systematic exhibition of the opinions of P. will be found in the *Republic*, or ideal commonwealth, of which an excellent English translation has been recently made by Davies and Vaughan. The *Republic* is not, as the title would lead us to suppose, a political work, like the *Politics* of Aristotle. It is, as Baron Bunsen well remarked, not so much a state as a church with which this great work has to do; or at least, both a state and a church; and the church is the superior and dominating element. In the *Republic*, accordingly, we find the necessity of virtue to the very idea of social life proved in the first book; then the whole process of a complete moral and scientific education is set forth with such fulness as to throw the strictly political part of the book, including the germs of what is now called political economy, very much into the shade.

The principles and government of an ideal moral organism, of which the rulers shall be types of fully developed and perfectly educated men, is the real subject of the *Republic*, which accordingly forms a remarkable contrast to the inductive results of the thoroughly practical work of Aristotle on the same subject. P.'s commonwealth is a theoretical construction of a perfect ideal state of society; Aristotle's is a practical discussion on the best form of political government possible under existing conditions. Of the value of P.'s work, both suggestively in the world of politics, and dogmatically in the region of moral and religious speculation, there can be no doubt; but as a practical treatise on politics, it is vitiated throughout, both by its original scheme, and by an inherent vice in the author's mind, which prevented him from recognizing the force of the actual in that degree which necessarily belongs to such a complex art as human government. Of this fault, the author was himself sufficiently conscious, and has accordingly, in another large political treatise, the *Laws*, endeavored, for practical purposes, to make some sort of compromise between the transcendental scheme of his *Commonwealth* and the conditions of existing society. But however he might modify individual opinions, there was a one-sidedness about P.'s mind, which rendered it impossible for him to struggle successfully with the difficulties of complex practical politics. He was too much possessed with the idea of order, and, moreover, had planted himself with too manifest a polemical attitude against Athenian democracy, to give due weight to the opposite principle of freedom, proved by experience to be so indispensable to every healthy and vigorous political development.

Physical science, in the days of P., stood on no basis sufficiently sure or broad to authorize a philosophy of the material universe with any prospect of success. Nevertheless, in his *Timæus*, the great philosopher of ideas has attempted this; and it is a work which, however valueless in the face of the grand results of modern chemical and kinetical research, will ever be consulted with advantage, as a grand constructive summary of the most important facts and theories of nature, known to the Greeks, before the accurate observations of Aristotle, and the extended mathematics of the Alexandrian school. The great question as to what matter is, and whence, P. nowhere seems to settle very clearly; but the general tendency of ancient thought was towards a dualism,

which recognized the independent existence of a not very tractable element called matter, in which P. seems to have acquiesced.

The works of P. were extensively studied by the Church Fathers, one of whom joyfully recognizes, in the great teacher of the Academy, the schoolmaster who, in the fulness of time, was destined to educate the heathen for Christ, as Moses did the Jews. A lofty passion for P. likewise seized the literary circle of the Medici at the period of the revival of letters in Italy. Since that time, the tyrannous sway of Aristotle, characteristic of the middle ages, has always been kept in check by a strong band of enthusiastic Platonists in various parts of Europe. Since the French Revolution particularly, the study of Plato has been pursued with renewed vigor in Germany, France, and England; and many of our distinguished authors, without expressly professing Platonism—as Coleridge, Wordsworth, Mrs. Browning, Ruskin, &c.—have formed a strong and a growing party of adherents, who could find no common banner under which they could at once so conveniently and so honorably muster as that of Plato.

The amount of learned labor expended on the text of Plato during the present century, has been in proportion; and in this department the names of Bekker, Ast, and Stallbaum stand pre-eminent. Professor Jowett also, in Oxford, has made P. his standard author for many years; from his hand we had, in 1871, his translation of the *Dialogues of Plato*. Mr. Grote, the historian of Greece, published his *Plato and the other Companions of Socrates* in 1864. One of the best accounts of the Platonic philosophy is given in Zeller's *Phil. der Griechen*, of which the part on P. and the *older Academy* was translated in 1876.

PLATOFF, MATVEI IVANOVITCH, COUNT, the Hetman of the Cossacks of the Don, and a Russian cavalry general, was born on the banks of the Don, 6th August 1757, and was descended from an ancient and noble family, which had emigrated from Greece. Having acquired a considerable reputation for wisdom and bravery, he was appointed by the Czar Alexander I. Hetman of the Cossacks; and subsequently, as a lieutenant-general in the Russian army, and afterwards as commander of the Russian irregular cavalry, he took a prominent part in the wars both with France and Turkey. After the French had evacuated Moscow, and retreated, P. hung upon their rear with the utmost pertinacity, wearying them out by incessant attacks, cutting off straggling parties, capturing their convoys of provisions, and keeping them in a state of continual terror and apprehension. The French historians state that Bonaparte's army suffered more loss from the attacks of P.'s Cossacks than from privation and exhaustion. He defeated Lefebvre at Altenburg.

After the rout of the French at Leipzig, he inflicted great loss upon them in their retreat, and subsequently gained a victory over them at Laon. The inhabitants of Seine-et-Marne will long remember him by the devastations and pillage committed by his undisciplined bands. He was enthusiastically welcomed by the Parisians (to their shame), and also by the English, who presented him with a sword of honor on the occasion of his visit to London in company with Marshal Blücher. The allied monarchs loaded him with honors and decorations, and the czar gave him the title of Count. He retired to his own country, there to mourn the death of his only son, who had been killed in the campaign of 1812, and died near Tcherkassk in 1818. No other Russian general ever exercised such an influence over the men under his command, and their awe of him was not greater than their affection; but this was doubtless owing to the inflexible and speedy justice which he administered to them, and to the freedom with which he left them to rob and pillage.

PLATO'NIC LOVE, the name given to an affection subsisting between two persons of different sex, which is presumed to be unaccompanied by any sensuous emotions, and to be based on moral or intellectual affinities. The expression has originated in the view of Plato, who held that the common sexual love of the race, harassed and afflicted with fleshly longings, is only a subordinate form of that perfect and ideal love of truth which the soul should cultivate. Whether such a sentiment as Platonic love can really subsist between persons of different sex, has been frequently disputed; but without pronouncing positively on a point so delicate, and depending so much on differences in our spiritual organization, it may be safely affirmed, that wherever a feeling—calling itself by this name—exists, it has undoubtedly a tendency to develop into something more definite and dangerous.

PLATOON (probably from the French *peloton*) was a term formerly used to designate a body of troops who fired together. A battalion was commonly divided into 16 platoons, and each company into two platoons, the platoon thus corresponding to the present subdivision. The word is obsolete in this its original sense; but it survives in the expression 'platoon exercise,' which is the course of motions in connection with handling, loading, and firing the musket or rifle.

PLATTE. See NEBRASKA.

PLATTEN-SEE. See BALATON.

PLA'TTSBURG, a village of New York, U.S., on the west shore of Lake Champlain, at the mouth of the river Saranac, which furnishes water-power to several mills and factories. It has a custom-house, academy, and six churches. In Plattsburg Bay was fought the naval battle of Champlain, in which the British flotilla, under Commodore Downie, was defeated by the American commodore M'Donough, September 11, 1814; while the land forces, amounting to 14,000 men, under Sir George Prevost, were defeated by General Macomb. Pop. in 1870, 5159.

PLA'TYPUS. See DUCK-BILL.

PLATY'STOMA (Gr. broad-mouth), a genus of fishes of the family *Siluridae*, having a very flat (depressed) snout, and a very large mouth with six long barbels; the skin quite destitute of scales; two dorsal fins; the eyes lateral, level with the nostrils. The species are numerous, some of them attaining a large size, many of them notable for their distinct and conspicuous markings. Several are natives of the rivers of the north-east of South America; and among these are some of the most beautiful and delicious of fresh-water fishes, as *P. tigrinum*, known among different tribes of Indians by various names—*Corutto*, *Colite*, *Oromi*, &c., which has an elongated body, light blue, transversely streaked with black and white, and a spreading forked tail. It is both taken by baited hooks and shot with arrows by Indians, as are several other species, some of which are found as far south as Buenos Ayres.

PLAU'EN, an important manufacturing town of Saxony, in a beautiful valley on the White Elster, 74 miles south of Leipzig by railway. It was the chief town of the Saxon Voigtland, and its castle was at one time the residence of the Voigt, or Imperial commissioner, but is now used as the seat of justice and other courts. P. contains a gymnasium, a royal palace, and numerous educational and benevolent institutions. It carries on extensive manufactures of muslin, cambric, and jaconet goods, as well as embroidered fabrics and cotton goods. In September 1844, 150 buildings were destroyed by fire, and after that event, the town was almost wholly rebuilt. Pop. (1875) 28,756; (1880) 35,078.

PLAU'TUS, M. ACCIUS, or, more correctly, T. MACCIUS, the great comic poet of Rome, was born about 254 B.C. at Sarsina, a village of Umbria. We have no knowledge of his early life and education; but it is probable that he came to Rome while still a youth, and there acquired a complete mastery of the Latin language in its most idiomatic form, as well as an extensive familiarity with Greek literature. It is uncertain whether he ever obtained the Roman franchise. His first employment was with the actors, in whose service he saved an amount of money sufficient to enable him to leave Rome and commence business on his own account. What the nature of this business was, or where he carried it on, we are not informed; we know, however, that he failed in it, and returned to Rome, where he had to earn his livelihood in the service of a baker, with whom he was engaged in turning a hand-mill. At this time—a few years before the outbreak of the Second Punic War—he was probably about 30 years of age; and while employed in his humble occupation, he composed three plays, which he sold to the managers of the public games, and from the proceeds of which he was enabled to leave the mill, and turn his hand to more congenial work. The commencement of his literary career may, therefore, be fixed about 224 B.C., from which date he continued to produce comedies with wonderful fertility, till 184, when he died in his 70th year. He was at first contemporary with Livius Andronicus and Nævius; subsequently with Ennius and Cæcilius.

Of his numerous plays—130 of which bore his name in the last century of the republic—only 20 have come down to us. Many of them, however, were regarded as spurious by the Roman critics, among whom Varro in his treatise (*Quæstiones Plautinæ*) limits the genuine comedies of the poet to 21. With the exception of the 21st, these Varronian comedies are the same as those we now possess. Their titles, arranged (with the exception of the Bacchides) in alphabetical order, are as follows: 1, *Amphitryo*; 2, *Asinaria*; 3, *Aulularia*; 4, *Capitoli*; 5, *Curculio*; 6, *Casina*; 7, *Cistellaria*; 8, *Epidicus*; 9, *Bacchides*; 10, *Mostellaria*; 11, *Menæchmi*; 12, *Miles*; 13, *Mercator*; 14, *Pseudolus*; 15, *Pænulus*; 16, *Persa*; 17, *Budens*; 18, *Stichus*; 19, *Trinummus*; 20, *Truculentus*; 21, *Vidularia*. As a comic writer, Plautus enjoyed immense popularity among the Romans, and held possession of the stage down to the time of Diocletian. The vivacity, the humor, and the rapid action of his plays, as well as his skill in constructing plots, commanded the admiration of the educated no less than of the unlettered Romans; while the fact that he was a national poet prepossessed his audiences in his favor. Although he laid the Greek comic drama under heavy contributions, and 'adapted' the plots of Menander, Diphilus, and Philemon with all the license of a modern playwright, he always preserved the style and character native to the Romans, and reproduced the life and intellectual tone of the people in a way that at once conciliated their sympathies. The admiration in which he was held by his contemporaries de-

scended to Cicero and St. Jerome; while he has found imitators in Shakspeare, Molière, Dryden, Addison, and Lessing, and translators in most European countries. The only complete translation of his works into English is that by Thornton and Warner (5 vols., 1767–1774). Unfortunately the text of his plays, as they have come down to us, is in such a very corrupt state, so defective from lacunæ, and so filled with interpolations, that much yet remains to be done by the grammarian and the commentator before they can be read with full appreciation or comfort. The *editio princeps* was printed at Venice in 1742. Weise and Fleckeisen have given us good modern editions; but that of Ritschl (1st ed. 1848–54; 2d ed. 1871) shows such admirable acuteness and learning as to have superseded all others.

PLAYFAIR, JOHN, a Scottish mathematician and natural philosopher, was born at Benvie in Forfarshire, March 10, 1748. His father, who was minister of the united parishes of Liff and Benvie, sent him to the university of St. Andrews at the age of 14, to study with a view to the ministry; and here P. obtained great reputation as a diligent and successful student, especially in mathematics and natural philosophy; so much so, that while a student, he for some time discharged the duties of the Natural Philosophy chair during the illness of the professor. In 1773, he entered the ministry, and succeeded his father in the parish of Liff and Benvie. During his leisure hours, he still prosecuted his favorite studies, the fruits of these labors being two memoirs, *On the Arithmetic of Impossible Quantities*, and *Account of the Lithological Survey of Schikallion*, which were communicated to the Royal Society of London. In 1783, he resigned his parochial charge to superintend the education of the sons of Mr. Ferguson of Raith; and in 1785, he became joint-professor of Mathematics along with Adam Ferguson in the university of Edinburgh; but exchanged his chair for that of Natural Philosophy in 1805. He took the part of Mr. (afterwards Sir John) Leslie (q. v.), his successor in the Mathematical chair, and published a pamphlet full of biting satire against the 'new-sprung zeal for orthodoxy.' He became a strenuous supporter of the 'Huttonian theory' in geology, and after publishing his *Illustrations of the Huttonian Theory of the Earth* (Edin. 1802), he made many journeys for the sake of more extensive observations, particularly in 1815, when he visited France, Switzerland, and Italy. He died at Edinburgh, 19th July 1819.

P., according to Jeffrey (*Annual Biography*, 1820), 'possessed in the highest degree all the characteristics both of a fine and a powerful understanding; at once penetrating and vigilant, but more distinguished, perhaps, by the caution and success of its march, than by the brilliancy or rapidity of its movements.' P. was, during the later part of his life, Secretary to the Royal Society of Edinburgh. From 1804, he was a frequent contributor to the *Edinburgh Review*, criticising the works of Laplace, Zach, and Kater, and the great trigonometrical surveys, both French and English, which had just been completed. He also wrote the articles 'Apinus' and 'Physical Astronomy,' and an incomplete 'Dissertation on the Progress of Mathematical and Physical Science, for the *Encyclopædia Britannica*. His contributions to the *Transactions of the Royal Society of Edinburgh* are numerous and exceedingly varied, a treatise on 'Naval Tactics' even appearing among them. His separate works are the *Elements of Geometry* (Edin. 1795), containing the first six books of Euclid, with supplementary articles on Trigonometry, Solid Geometry, and the Quadrature of the Circle; and his *Outlines of Natural Philosophy* (Edin. 1812 and 1816), being the heads of his lectures delivered in the university on that subject. A third volume of the *Outlines*, completing the work, was promised but never appeared.

PLEA is a technical term in the law of the United Kingdom. In England, it had a very restricted meaning, being confined to the pleading of a defendant to an action at common law. Now in all actions in the High Court it is called the 'Statement of Defence.'—In Scotland, it is not used in the same sense, but denotes the short legal ground on which a party, whether pursuer or defender, bases his case or pleading. Hence the pleas in law are only short propositions of law. Pleas are subdivided according to their subject-matter, into pleas dilatory and peremptory, pleas of abatement, pleas to the jurisdiction. Pleas in bar are the same as peremptory pleas; but in criminal cases in England, special pleas in bar are pleas stating some ground for not proceeding with the indictment, such as a plea of former acquittal, or autrefois acquit; or of conviction, or autrefois convict; or a plea of pardon.—In Scotland, a 'plea of panel' means a plea of guilty or not guilty. Pleas of the crown was an expression anciently used to denote the divisions of criminal offences generally, as in the well-known work called *Pleas of the Crown*, by Sir Matthew Hale, and other writers. The phrase was so used because the sovereign was supposed in law to be the person injured by every wrong done to the community, and therefore was the prosecutor for every such offence.

PLEADING, as a Legal term, has two meanings—a restricted and a general meaning. In the former sense it is a generic term to denote the written formula containing the subject-matter of a litigant's demand, or claim, or of his defence or answer thereto. In its general sense, it denotes that system of rules on which the particular pleadings of litigants are framed. In the practice of English common law, the pleadings in an action were called the declaration, plea, replication, rejoinder, surrejoinder, rebutter, surrebutter, &c.—the first being a statement of the plaintiff's demand; the second, the defence thereto, and so on, each alternately answering the other, until the parties arrive at a stop, called an issue, which means a proposition of fact, which the one affirms, and the other denies. When an issue is arrived at, the parties can go no further; and the next step is to send the issue before a jury, that they may decide it. When the parties differ, not on a question of fact, but on one of law, it is called a demurrer, which must be decided by the court. These technical names have, however, been recently much changed. In the High Court of Justice, the plaintiff's pleading is called his 'Statement of Claim'; then follow the 'Statement of Defence,' the reply, &c., there being no further pleadings.—In Scotland, the pleadings of the parties are called the summons (including the condescendence), the defences or answers, the revised condescendence, the revised answers, &c. The peculiar technical rules to which the pleadings of parties must conform, are capable of being understood only by lawyers.

PLEBEI'ANS (Lat. *plebs*, from same root as Lat. *impleo*, to fill; and Gr. *plethos*, multitude), the common people of Rome; one of the two elements of which the Roman nation consisted. Their origin, as a separate class, is to be traced partly to natural, and partly to artificial causes. The foundation of Rome, probably as a frontier-emporium of Latin traffic (according to Mommsen's suggestion), would bring about the place a number of inferior *employés*, clients, or hangers-on, of the enterprising commercial agriculturists, who laid the primitive basis of the material and moral prosperity of the city. These hangers-on were the original plebeians, or non-burgesses of Rome, whose numbers were constantly increased by the subjugation of the surrounding cities and states. Thus, tradition states that, on the capture of Alba, while the most distinguished citizens of that town were received among the Roman patricians, the greater part of the inhabitants, likewise transferred to Rome, were kept in submission to the *populus* or patricians of Rome—in other words, swelled the ranks of the plebeians. Similar transfers of some of the inhabitants of conquered towns are assigned to the reign of Ancus Martius. The order of plebeians thus gradually formed, soon exceeded the patricians in numbers, partly inhabiting Rome, and partly the adjoining country. Though citizens, they were neither comprehended in the three tribes, nor in the *curia*, nor in the patrician *gentes*, and were therefore excluded from the comitia, the senate, and all the civil and priestly offices of the state. They could not intermarry with the patricians.

The first step (according to traditionary belief) towards breaking down the barrier between the two classes was the admission, under Tarquinius Priscus, of some of the more considerable plebeian families into the three tribes. Servius Tullius divided the part of the city and the adjacent country which was inhabited by plebeians, into regions or local tribes, assigning land to those plebeians who were yet without it. The plebeian tribes with tribunes at their head, formed an organization similar to that of the patricians. The same king further extended the rights of the plebeians by dividing the whole body of citizens, patrician and plebeian, into five classes, according to their wealth, and forming a great national assembly called the *Comitia Centuriata*, in which the plebeians met the patricians on a footing of equality; but the patricians continued to be alone eligible to the senate, the highest magistracy, and the priestly offices. These newly-acquired privileges were lost in the reign of Tarquinius Superbus, but restored on the establishment of the Republic. Soon afterwards, the vacancies which had occurred in the senate during the reign of the last king, were filled up by the most distinguished of the plebeian equites, and the plebeians acquired a variety of new privileges by the laws of Valerius Publicola. The encroachments on those privileges on the part of the patricians, began the long-continued struggle between the two orders, which eventually led to the plebeians gaining access to all the civil and religious offices, acquiring for their decrees (*plebiscita*) the force of law. Under the Hortensian law (286 B.C.), the two hostile classes were at last amalgamated in one general body of Roman citizens with equal rights. Henceforth, the term *populus* is sometimes applied to the plebeians alone, sometimes to the whole body of citizens assembled in the *Comitia Centuriata* or *Tributa*, and *plebs* is occasionally used in a loose way for the multitude or populace, in opposition to the senatorial party. See **PATRICIAN**.

PLEBISCITE, the name given, in the political phraseology of modern France, to a decree of the nation obtained by an appeal

to universal suffrage. Thus Louis Napoleon, for example, was chosen president, and subsequently emperor, by a plebiscite. The word is borrowed from the Latin; but the *plebiscitum* of the Romans properly meant only a law passed at the *Comitia Tributa*, i. e., assembly of the *plebs*, or 'commons,' as distinguished from the *populus*, or the 'nobles;' and although it was ultimately obligatory on both classes of the community, it, of course, could only refer to such matters as it was within the province of the *Comitia Tributa* to legislate upon, and could not fundamentally alter or destroy the constitution.

PLECTOGNATHI, in the system of Cuvier, and also in that of Müller, an order of osseous fishes, but having the skeleton less perfectly ossified than osseous fishes generally; the skin furnished with ganoid scales or spines; and particularly characterized by having the maxillary and premaxillary bones ankylosed or soldered together. The gill-lid and rays are concealed under the thick skin, with only a small opening. The ribs are very short, and there are no distinctly developed ventral fins. The fishes belonging to this order are not many. They are regarded as a connecting link between the osseous and the cartilaginous fishes.

PLEDGE is the depositing of a chattel or movable with a creditor in security of a debt, and is a contract between the parties that the pledgee shall keep the chattel till the debt is paid. In England, when A pledges property with B for a debt, and other debts are incurred, B cannot retain the pledge for the additional debts; but in Scotland, this can be done. When chattels are pledged in England for debt, the pledgee may sell the goods, if the debt is not paid at the time agreed, or within a reasonable time after notice given; but in Scotland this can only be done by getting the authority of the sheriff and a warrant to sell the goods. Owing to the frequent occasions of poor and needy persons to pledge their goods in order to procure advances of money for temporary purposes, the legislature has enacted a code of special laws to regulate these contracts. See **PAWNBROKING**.

PLEI'ADÉS, in Greek Mythology, were, according to the most general account, the seven daughters of Atlas and Pleine, the daughter of Oceanus. Their history is differently related by the Greek mythologists: according to some authorities, they committed suicide from grief, either at the death of their sisters, the Hyades, or at the fate of their father, Atlas (q. v.); according to others, they were companions of Artemis (Diana), and being pursued by Orion (q. v.), were rescued from him by the gods by being translated to the sky; all authorities, however, agree that, after their death or translation, they were transformed into stars. Only six of these stars are visible to the naked eye, and the ancients believed that the seventh hid herself from shame that she alone of the P. had married a mortal, while her six sisters were the spouses of different gods. Their names are Electra, Maia, Taygete, Alcyone, Celeno, Sterope (the invisible one), and Merope.

In Astronomy, a group or constellation of six stars placed on the shoulder of Taurus, the second sign of the Zodiac, and forming, with the pole-star and the twin Castor and Pollux, the three angular points of a figure which is nearly an equilateral triangle. Many believe, from the uniform agreement that the P. were 'seven' in number, that the constellation at an early period contained 'seven' stars, but that one has since disappeared; not a very uncommon occurrence.

The name *Poetical Pleiades* is frequently applied to reunions of poets in septenary groups; and this use of the word dates from the time of Ptolemies—the originator of the first being Ptolemy Philadelphus, who, from the number of the Greek poets that flocked to Alexandria, chose out seven, whom he treated with special distinction, and denominated his *pleiad*. His example was followed by Charlemagne; and the same system was kept up by the 'Compagnie des Sept Mantenadors del gay Saber,' or the 'Compagnie des Sept Troubadours de Toulouse,' down till the 17th century. Such associations were valuable as promoting an interchange of ideas and opinions by the most eminent in the same department of letters, and creating a kind of *esprit du corps* among them.

PLEI'OCENE (Gr. more recent), the name given by Sir Charles Lyell to a section of the Upper Tertiaries, because the organic remains found in it contain between 60 and 70 per cent. of living species; a greater proportion than exists in the older Miocene, but not so great as that found in the succeeding Pleistocene.

The beds belonging to this period are very local. They have been noticed in several places in Europe, but have been chiefly studied in Suffolk, the only locality in which they occur in Britain. Here they cover the upper beds of the London Clay; and being composed of shelly sand, they have, like similar deposits, been used for fertilizing lands deficient in calcareous matter, and have received the local name of 'Crag.' They are divided into the (1) Red Crag, 50 feet; (2) Coralline Crag, 50 feet.

The Red Crag consists of beds of quartzose sands and gravel with a mixture of shells, for the most part rolled, and sometimes broken up into sand. The whole deposit, with the contained fos-

sils, has a deep ferruginous or ochreous color. It seems to have been formed in shallow water, the currents of which have given it a very variable character, and frequently confused the stratification, as in some modern sandbanks. The fossils have a somewhat boreal character. They consist chiefly of mollusca; but there have been also found the bones and teeth of large sharks, skates, and other fish, and the ear-bones of one or more true whales.

The Coralline Crag is generally calcareous and marly, consisting of a mass of shells and polyzoa, separated in some places by thin layers of hard limestone, and coral-like masses, which occupy the position in which they lived. It is easily separated from the Red Crag by its white color. It has been formed at a greater depth and in more tranquil water than the newer deposit. The fossils have a more southern facies than those of the Red Crag, and indicate that they lived in an ocean with a higher temperature. Among these southern forms may be mentioned species of the genera *Conus*, *Oliva*, *Mitra*, *Voluta*, and *Pyrula*. The calcareous polyzoa are abundant and very beautiful; and several interesting forms of echini have been described. A few fossils of the same species as those occurring in the London Clay have been found in this and the Red Crag, but these are believed to have been washed out of the inferior deposits.

Mr. Searles Wood has obtained 345 species of testacea from the Coralline Crag, and 230 from the Red Crag, of which about 150 are common to both; about 70 per cent. of the newer division are also recent, and about 60 per cent. of the older.

Pleiocene deposits have been observed in the neighborhood of Antwerp and on the banks of the Scheldt, from which 200 species of shells have been obtained, two-thirds of which were already known from Suffolk. More than a half are recent species found in the northern seas, and a few are still living in the Mediterranean. Similar deposits occur in Normandy. The low hills between the Apennines and the sea on each side of Italy are formed to a considerable extent of beds belonging to this period; and the marine strata of the seven hills of Rome are of the same age. Beds of a brackish-water origin, observed on the shores of the Caspian, Aral, Azof, and Black Seas, have been referred to this period.

PLEIOSAU'RUS (Gr. literally 'more a lizard,' i. e., than the *Plesiosaurus*), a genus of fossil sea-reptiles nearly allied to the *Plesiosaurus* but having a very short neck, and comparatively a larger head. The jaws also are furnished with stronger teeth, which are subtriangular in cross section, with one side flattened, and bounded by prominent lateral ridges on the more convex sides. Three species have been described. They are peculiar to the Oxford and Kimmeridge clays of the Upper Oolite Period.

PLEI'STOCENE (Gr. most recent), or **NEWER PLEIOCENE**, terms introduced by Sir Charles Lyell to designate the most recent Tertiary deposits, the organic remains of which belong almost exclusively to existing species. Within the last few years, no section of the earth's crust has received so much attention as the strata included under this name. The obscurity arising from great antiquity and metamorphic changes in deposits, and the consequent necessity of calling to some extent on the imagination in investigations into the older strata, have always thrown a peculiar charm round geology; but the examination of the little changed newer deposits, containing animals scarcely differing in genera from, and many of them the same even in species as, those now living, being based on simple observation, has been overlooked, although the best method in all obscure inquiries is that which starts from the known, and gradually proceeds to the unknown. The Palæozoic rocks have been carefully grouped and classified, and the fossils described and figured; while the order and contents of the Pleistocene deposits are little known. Their isolated nature to some extent accounts for this; but, on the other hand, as they exhibit the changes that have immediately preceded the present order of things, and so give us the first sure footing in our progress downwards, they deserve the most careful attention.

Not only in organic contents, but in the physical conditions under which they were deposited, the Pleistocene strata show that the earth, as regards its general temperature, was, at the time of their deposition, in a condition nearly approaching to its present. There is consequently a considerable difference in the deposits and fossils of this period in the different regions of the world. The alluvial pampas of South America and the gravels of Australia exhibit, by their structure and contents, a temperature of some warmth; while corresponding deposits of Britain and the continent show a state of cold that is scarcely conceivable at so recent a period. The whole of Northern Europe must have been under ice like the interior of Greenland at the present day. Perhaps the best classification of the deposits is one based on the relation which they bear to the temperature of the period when they were formed. The oldest Pleistocene deposits represent a time of intense cold. They were formed at the bottom of a sea

into which immense glaciers forced their way. The fine mud in which the organic remains are buried was obtained from the melting glaciers. All the shells belong to species now living in arctic or boreal seas. The Bridlington beds, near Flamborough Head, consisting of sand, clay, and pebbles, with numerous marine shells, belong to this period. Of the 63 species determined by Dr. Woodward, one-half are at present living only in seas north of Britain. The clay deposits on the east of Scotland, at Elie and Errol, lately described by the Rev. Thomas Brown, contain fossils that have a similar arctic facies. The shells of the Bridlington, Elie, and Errol deposits differ from those of the other Pleistocene strata in being much more arctic, and they consequently show that the cold had reached its climax at the time of their formation. To this period most probably belongs the boulder-clay of the south of England, which contains erratics from Scandinavia. Both the clay and the boulders seem to have been transported to their present position by floating icebergs.

The temperature, however, after a time improved, reducing the extent of the ice-covering, and driving the arctic fauna northwards from our shores. In the Norwich Crag, we find a larger proportion of southern species, only one-sixth of these being truly arctic. This deposit, found in the neighborhood of Norwich, consists of beds of sand and gravel which contain fresh-water and marine shells, and the bones of large mammalia. Contemporaneous with the Norwich Crag are the marine deposits of the Clyde, at least the older of them, for though the fossils of all the beds have hitherto been grouped together, they certainly represent two periods which differ from each other by reason of the increasing temperature. While these beds were being deposited around the shores, the ice was disappearing from the land. The glaciers were gradually creeping inwards, leaving an ever-increasing margin of bare land between the glaciers and the sea, which they covered with a continuous layer of mud and rubbed stones—the materials taken up in their progress over the surface—and so forming the boulder-clay of Scotland and the north of England. This is a remarkable deposit of unstratified mud, the character and color of which is influenced by the rocks on which it rests, and from which it was derived. It contains numerous rounded and polished blocks of stone of various sizes, promiscuously scattered through it, the whole seeming to be the result of an irregular pell-mell hurrying forward and deposition of the materials. It has been always a puzzle to geologists (see BOULDER-CLAY); but Mr. Geikie, in his recently published Memoir, by showing it to be the terminal moraine formed by the slowly retreating sheet of glacier-ice, has given an explanation which meets all the singular phenomena connected with it. Connected with the disappearance of glaciers, are the lateral moraines which exist on many hillsides; and perhaps a little later, the long ridges of gravel which are called Kames in Scotland, and Eskers in Ireland. The loamy deposits of the valleys of the Rhine and the Danube, known as the Loess, were formed at this time by the fine mud from the glaciers, with which every torrent rushing from the icy cavern at the termination of a glacier is charged, a process now going on, on parts of the coast of Greenland (see GLACIAL PERIOD).

When the glaciers began to disappear, mammalia again occupied the land; their remains, we have already seen, occur in the Norwich Crag. They continued to increase as the conditions for their existence improved. The caves of the British Islands and the continent were inhabited by hyenas, bears, and other wild beasts, which have left their remains buried in the mud at the bottom of the caves. The raised sea-beaches of this period contain the shells of mollusca now living in the neighboring seas. In many places around the shores of Britain and Ireland, submarine forests are met with dipping down under low water, and exhibiting the stumps and roots of trees, in the position of growth, belonging to species now living in Britain. Some of the older peat-bogs require to be placed also among the later Pleistocene deposits.

The classification, then, of these strata, which we propose, from the light thrown on them by recent observation, may be put into the following tabular form. The subdivisions are the names of recognized deposits, and though arranged in tabular series, the order is not one of strict sequence, representing the superposition of the different beds; they are all very local deposits, and many of them, though differing in character, were formed contemporaneously.

	{ Peat-bogs.
Post-Glacial.	{ Submarine Forests.
	{ Modern Raised Sea-beaches.
	{ Cave Deposits.
	{ Loess.
	{ Kames and Eskers.
Glacial.	{ Lateral Moraines.
	{ Boulder-clay.
	{ Newer Clyde Beds.
	{ Older Clyde Beds.
Arctic.	{ Elie, Errol, and Tirie Clay Beds.
	{ Bridlington Beds.

Many speculations have been made as to the causes of the remarkable change of temperature, from the comparatively warm period of the Pleistocene deposits, to the extreme cold of the early Pleistocene strata, and the subsequent gradual return to the warmer temperature of the present period. The most probable is, that it resulted from an extensive depression of the land of the northern hemisphere in some parts, and its elevation in others during the period. Deposits of glacial shells have been found more than 1000 feet above the sea-level in Wales. A depression much less than this, in the Isthmus of Panama, would give a different direction to the Gulf Stream, and so deprive Western Europe of its benignant influences. It would also put the immense sandy Sahara under water; and that it has been so at a comparatively recent period, has been clearly established by the discovery lately of existing marine shells (including *Cardium edule*) over an extensive district of the desert. Without the Sahara, the south of Europe would have no burning dry sirocco, which now melts the glaciers of the Alps; but instead, a comparatively cold sea-breeze, laden with moisture, which would to a large extent feed them. The existence of a greater quantity and a higher elevation of land near the North Pole would also depress the temperature. These and similar causes would do much, if they were not in themselves sufficient, to produce the extreme cold of the arctic period.

The classification of the British strata will suit, in a general way, the whole of the North Temperate Zone, for throughout the whole of the northern regions of Europe, Asia, and America, similar conditions existed, producing similar physical changes, and the whole region formed one zoological province inhabited by the Mammoth, Mastodon, and their contemporaries. A warmer climate prevailed at this period in South America, and the fossil animals there belong to types still peculiar to that continent, though of a size immensely greater than their living representatives. The Megatherium, Mylodon, and Megalonyx were the gigantic fore-runners of the living sloth; and the small armadillos were anticipated by the Glyptodon. The llamas, opossums, tapirs, and prehensile-tailed monkeys are the diminutive representatives of similar forms in the Pleistocene period. The peculiar marsupial fauna of Australia had also its gigantic fore-runners during this period. The skull of one species (*Diprotodon*, an animal between the kangaroo and the wombat), now in the British Museum, measures three feet in length. The huge wingless *Dinornis*, and its allies of New Zealand, were nearly allied to the small wingless *Apteryx*, now living in that island.

The question of the antiquity of man is intimately associated with the Pleistocene deposits. Whatever be the age of the beds in which either the remains of man or works of art have been found, it is certain that none of them pass the horizon of the boulder-clay. It is, however, equally certain that undoubted evidences of his existence contemporaneously with the mammoth and woolly rhinoceros, with the cave-lion and hyæna, have been found in Britain; and setting aside the various French and Belgian caves and gravel deposits about which geologists are, with good cause, so divided, there is evidence in the knives, pins, &c., manufactured from the bones of the large reindeer, found in caves at Bruniquel and elsewhere, that man hunted this huge extinct animal. Its contemporaries, as far as the associated remains from these caves have been determined, yet survive: these were the chamois, ibex, horse, fox, wolf, hare, raven, partridge, and salmon. However far, when measured by years, this carries back the first appearance of man on the globe, geologically speaking, the time is insignificant as compared with the vast lapse of ages represented by even a single formation; still it represents a period in which many remarkable changes have taken place.

PLENIPOTENTIARY. See ENVOY.

PLE'NISHING, in the law of Scotland, denotes the furniture of a house or stocking of a farm. The term is now seldom used, except in the law relating to heirship Movables (q. v.).

PLE'ONASM (Gr. *pleon*, more), a term employed in Rhetoric to denote superfluity of expression.

PLESIOSAURUS (Gr. near to a lizard), a remarkable genus of fossil sea-reptiles, the species of which are found in the Lias,

Plesiosaurus.

Oolite, and Cretaceous measures. Its remains are so abundant and so perfectly preserved, that we are as well acquainted with skeletons of many of its species as we are with those of any living animals. These represent a strange animal, the structure of which Cuvier considered to be the most singular, and its character the most anomalous, that had been discovered amid the ruins of former worlds. In the words of Buckland: 'To the head of a lizard, it united the teeth of a crocodile, a neck of enormous length, resembling the body of a serpent, a trunk and tail having the proportions of an ordinary quadruped, the ribs of a chameleon, and the paddles of a whale.'

The skull is small and depressed. From the nostrils backwards, it is quadrate; it suddenly contracts at the nostrils, and is continued into a parallel-sided apex, which is sometimes slightly swollen at the point. No sclerotic plates have been found in the orbits. The rami of the lower jaw are remarkably expanded at their anterior ankylosed extremity. No intervening vacuity separates the angular and surangular pieces, as in the crocodiles, but they are joined throughout, as in the lizards. The teeth occupy distinct cavities; they are sharp-pointed, long, slender, circular in cross section, and with fine longitudinal ridges on the enamel. The most striking peculiarity of the vertebrae is the great length of the neck-portion, which is composed of from 20 to 40 vertebrae. The articular surfaces of the bodies of the vertebrae are either flat or slightly convex in the center, with a concavity round the periphery. The cervical vertebrae consist of a centrum, neural arch, and two ribs, which articulate into two pits on the sides of the centrum. In the dorsal vertebrae, the ribs are articulated to diapophyses from the neural arch; and in the tail, they gradually descend again to the sides of the centrum. The tail is much shorter than in the ichthyosaurus. In the abdominal region, the extremities of each pair of ribs are connected below by the development of the hæmal spine.

The two pair of limbs were equal in size and shape, with probably a single exception. The bones of the hind-limbs closely correspond in number, arrangement, and form with those of the fore-limbs, so that the descriptions of the one set answer to the corresponding bones of the other. The humerus is a stout and moderately long bone, curved slightly backwards, rounded at its proximal extremity, and flattened as it approaches the elbow joints. The radius and ulna are short and flat bones—the former straight, the latter reniform, with the concavity toward the radius. The carpus consists of six to eight flat round bones in a double row. The five metacarpals are long, slender, and slightly expanded at both ends. The numerous phalanges are alike in form, but progressively decrease in size. The radial digit has generally three; the second from five to seven; the third, eight or nine; the fourth, eight; and the fifth, five or six phalanges. The limbs were covered with integument, so as to form simple undivided paddles, as in the turtle.

The supposed habits of the plesiosaur are thus described by Conybeare: 'That it was an aquatic, is evident from the form of its paddles; that it was marine, is almost equally so, from the remains with which it is universally associated; that it may have occasionally visited the shore, the resemblance of its extremities to those of the turtle may lead us to conjecture; its motion must have, however, been very awkward on land; its long neck must have impeded its progress through the water, presenting a striking contrast to the organization which so admirably fits the ichthyosaurus to cut through the waves.

May it not, therefore, be concluded—since, in addition to these circumstances, its respiration must have required frequent access to the air—that it swam upon or near the surface, arching back its long neck like the swan, and occasionally darting it down at the fish which happened to float within its reach? It may perhaps have lurked in shoal-water along the coast concealed among the sea-weed, and, raising its nostrils to the surface from a considerable depth, may have found a secure retreat from the assaults of dangerous enemies; while the length and flexibility of its neck may have compensated for the want of strength in its jaws, and its incapacity for swift motion through the water, by the suddenness and agility of the attack which they enabled it to make on every animal fitted for its prey which came within its reach.'

The first remains of this animal were discovered at Lyme Regis in 1822. Since then, twenty-two species have been described, the specific differences chiefly resting on peculiarities in the form and structure of the vertebrae.

PLETHORA (Gr. 'fulness' or 'excess'), designates a general excess of blood in the system. It may arise either from too much blood being made, or from too little being expended. The persons who become plethoric are usually those in thorough health, who eat heartily and digest readily, but who do not take sufficient bodily exercise, and do not duly attend to the action of the excreting organs. With them, the process of blood-making is always on the increase, and the vessels become more and more filled, as is seen in the red face, distended veins, and full pulse.

The heart is excited and overworked, and hence palpitation, shortness of breath, and probably a sleepy feeling, may arise; but these symptoms, instead of acting as a warning, too often cause the abandonment of all exercise, by which the morbid condition is aggravated. The state of plethora thus gradually induced may be extreme without any functions materially failing, and yet the subject is on the verge of some dangerous malady, such as apoplexy, or structural disease of the heart or great vessels, or of the lungs, kidneys, or liver.

Plethora is said to be *sthenic* when the strength and irritability of the muscular fibres (especially of the heart and arteries) are fully or excessively developed. This form commonly affects the young and active, and those of sanguineous nature. The blood is rich in red cells and fibrine; and there is a tendency to general febrile excitement, active hæmorrhages, fluxes, and inflammation. A natural cure is thus often effected by the supervention of an attack of bleeding from the nostrils or from piles, or of mucous or bilious diarrhœa. The plethora is said to be *asthenic* (Gr. *a*, not; and *sthenos*, strength) when there is a deficiency of contractility and tone in the muscular fibre. In this case, the heart and vessels, instead of being excited (as in sthenic plethora) by the augmented quantity of blood, are oppressed by its load, and cannot duly expel their accumulated contents. The face is purple instead of red; the extremities cold, and the excreting organs sluggish. This form affects persons weakened by age, excesses, or previous disease. It tends to produce congestions and passive hæmorrhages, fluxes, and dropsies; and, if continued, structural changes, such as dilatation of the heart, enlarged liver, varicose veins, &c.

In *sthenic* plethora, blood-letting is the first remedy, and this, with the continued use of aperient medicine and a sparing diet, is often sufficient to complete the cure. If these means fail, recourse must be had to antimonials, salines, digitalis, and sometimes mercury or colchicum. In the *asthenic* form, Dr. Williams (to whose article on 'Plethora,' in his *Principles of Medicine*, we refer our readers for further details) observes that 'the continued use of alterative aperients and diuretics, such as mild mercurials, with rhubarb, aloes, or senna, salines and taraxacum, nitric acid, iodide of potassium, &c., may prepare the way for various tonics, such as calumba, bark, and iron.' He also recommends the use of the Cheltenham, Leamington, and Llandrindod waters; first the saline, which are aperient and diuretic; and afterwards the chalybeate, which, although tonic, usually contain enough of saline matter to keep the secretions free.

Food may be taken more freely than in the sthenic form; and in both varieties, as much exercise in the open air should be taken as can be born without causing exhaustion.

PLEURÆ. Each lung is invested externally by a very delicate serous membrane termed the *pleura*, which, after enclosing the whole organ, except at its root, where the great vessels enter it, is reflected upon the inner surface of the thorax or chest. That portion of the pleura which is in contact with the surface of the lung is called the *pleura pulmonalis*, or visceral layer; whilst

A transverse Section of the Thorax, showing the reflections of the Pleura, and the relative position of the Viscera, &c. (From Gray's *Anatomy*.)

1, The visceral, and 2, the parietal layer of the pleura, on the right side; 3, 3, the ribs; 4, 5, section of the right and left lungs; 6, the heart; 7, the pulmonary artery, dividing into the right and left branches; 8, 8', the right and left pulmonary veins; 9, 9', the ascending and descending aorta, the intervening arch being cut away; 10, 10', the right and left bronchi; 11, the œsophagus; 12, body of dorsal vertebra; 13, the sternum.

that which lines the interior of the chest is called the *pleura costalis*, or parietal layer; while the space intervening between these two layers is called the *cavity of the pleura*. Each pleura, as will be at once seen by a reference to the figure, is a closed sac, and quite independent of the other. The interspace between the pleuræ on the right and left side, is termed the *mediastinum*.

tinum, and contains all the viscera of the thorax excepting the lungs.

The inner surface of each pleura is smooth, glistening, and moistened by a serous fluid; the outer surface is closely adherent to the surface of the lung, to the roots of the pulmonary vessels as they enter the lung, to the upper surface of the diaphragm, and to the walls of the chest. The lobes of the lungs are separated from one another by involutions or in-foldings of the visceral layer; two such involutions—one on either side—are shown in the figure. The use of these serous sacs is much the same as that of the *Peritoneum* (q. v.); each pleura retains the lung and, to a certain extent, the greater vessels in position, while it at the same time facilitates, within certain limits, the movements of those parts which are essential to the due performance of the act of respiration.

PLEURISY, or inflammation of the investing membrane of the lung, is one of the most serious diseases of the chest. It is very often, but by no means invariably associated with inflammation of the *substance* of the lung, commonly known as *Pneumonia* (q. v.). Pleurisy without pneumonia is much more common than pneumonia without pleurisy. When both are present, but pneumonia preponderates, the correct term for the affection is *pleuro-pneumonia*, although it is frequently spoken of simply as pneumonia, probably in consequence of the remedies being applied mainly to it, as the more important of the two elements in the compound malady.

The pleura being a serous membrane, its inflammation is attended with the same course of events as have been already described in our remarks on the two allied diseases, *Pericarditis* and *Peritonitis*. The inflammation is of the adhesive kind, and is accompanied by pain, and by the effusion of serum, of fibrinous exudation (the *coagulable lymph* of the older writers), or of pus, into the pleural cavity. In consequence of the anatomical relations of the pleura—one part of the membrane (the parietal) lining the firm walls of the chest, while the other part (the visceral) envelops the soft and compressible lung; and these opposed surfaces being freely movable on one another—it follows that very different effects may be produced by its inflammation. For example, the visceral layer may be glued to the parietal layer, so as to prevent all gliding movement between them, and to obliterate the pleural cavity (similarly to what often happens in *Pericarditis* q. v.); or the two surfaces which are naturally in contact, may be abnormally separated by an infusion of serum between them; or from a combination of these results, the opposite surfaces of the pleura may be abnormally united at some points, and abnormally separated at others.

The general symptoms of pleurisy are rigors, pain in the side, fever, difficulty and rapidity of breathing, cough, and an impossibility of assuming certain positions; and of these, the most marked is the pain or *stitch in the side*, the *Point de côté* of the French writers. From the prominence of this pain, which occupies a single spot, and is of a sharp, stabbing character, the Latin writers term pleurisy *Morbus lateris*. This spot is usually about the center of the mamma of the affected side, or just below it; but why the pain should be usually restricted to that one small spot, when the inflammation pervades a considerable extent of surface, is a question that has never received any satisfactory answer. The pain is, however, occasionally felt in other parts—as in the shoulders, in the hollow of the armpit, beneath the collar-bone, along the breast-bone, &c.

Cruveilhier observes that the pain sometimes affects the loins, and simulates lumbago; while Andral and Dr. Watson have directed attention to the fact, that the pain often affects the hypochondrium, and may be readily mistaken for a symptom of peritonitis, or (if occurring on the right side) of hepatitis. The pain is increased by percussion, by pressure between the ribs, by a deep inspiration, by cough, &c.; and the patient is often observed to suppress a natural desire to cough, or never to draw more than a short and imperfect inspiration. The cough is not invariably present, although it is an ordinary symptom. It is small, suppressed as far as possible by the patient, and is either dry, or accompanied by the expectoration of slight catarrh. If much frothy mucus is brought up, it is a sign that Bronchitis (q. v.) is also present, and the appearance of rust-colored sputa indicates the co-existence of pneumonia. Although the above named symptoms, especially when most of them occur together, afford almost certain evidence of the existence of pleurisy, yet to the physician the physical signs are still more valuable, especially those furnished by percussion and auscultation.

Pleurisy far more commonly arises from exposure to cold than any other cause, especially if a poisoned condition of the blood, predisposing to inflammation of the serous membrane, is present; but it may be occasioned by mechanical violence (as by a penetrating wound of the thorax by the splintered ends of a broken rib, &c.), or by the accidental extension of disease from adjacent parts. The disease may terminate in resolution and complete re-

covery; or in adhesion, which often only causes slight embarrassment of breathing: or it may end with such a retraction of one side of the chest as to render the corresponding lung almost or totally useless: or it may cause death either directly by actual suffocation, if the effusion is very copious, and is not removed by tapping; or indirectly, by exhaustion. It is seldom, however, that simple pleurisy proves fatal.

In acute pleurisy, occurring in a robust and previously healthy subject, free blood-letting should be at once resorted to. If there is a sharp stitch in the side, and the respiration is short, quick, and restrained, the patient should be bled, in the upright position, from a large orifice in the vein, until the pain is relieved, and he can draw a full breath without discomfort, or until he is about to faint; and if the pain and difficult breathing should return, and the pulse continue firm and hard, either the venesection must be repeated, or leeches must be freely applied to the painful side. The bowels should be freely evacuated, after which calomel should be given, guarded with a little opium, to the extent of producing *slight* mercurialization, with the view of checking the effusion of fluid. The more rapidly the system can be thus affected, the better, and hence it has been recommended (by Dr. Walsh) that during the first six hours a grain and a half of calomel, combined with a sixth of a grain of opium (or more, if the pain continues acute), should be given every half hour; while mercurial ointment is rubbed into the skin of the affected side, near the arm-pit, every fourth hour. Care must be taken that neither decided salivation nor narcotism is induced; and as soon as there is any evidence from the breath, or from the appearance of the gums, that the mercurial action has been established, the further administration of the calomel and the ointment must be suspended. After the pain and fever have ceased, we must facilitate the absorption of the fluid by diuretics. A pill composed of half a grain of digitalis, a grain of squills, and three grains of blue pill taken twice a day, usually acts efficiently; and the compound tincture of iodine of the London (*not* the British) Pharmacopœia, in doses of twenty minims, taken, largely diluted, three times a day, has been strongly recommended.

There has been considerable discussion of late years, as to how far the operation of tapping the chest, and letting out the fluid, is justifiable in this disease. The best authorities are of opinion that in simple pleurisy it ought never to be performed unless (1) the life of the patient is in immediate danger from the continued pressure of the fluid in the sac; (2) unless all other means of getting rid of the fluid having failed, the patient is evidently losing strength daily; and (3) unless there is good reason to believe that the fluid consists of pus, in which case it should be let out. In all cases in which the operation is contemplated, a grooved needle should be introduced into the pleura. By this means, we not only ascertain the actual presence of fluid, but we discover its nature. If it be serous, it will flow readily along the groove, and trickle down the patient's side; if it be purulent and thick, a drop or two will probably be visible at the external orifice, and when the needle is withdrawn, its groove will be found to contain pus. The puncture thus made is quite harmless, and inflicts very little pain.

PLEURISY ROOT. See BUTTERFLY WEED.

PLEURODY'NIA is a rheumatic affection of the intercostal muscles, and is characterized by acute pain in the side upon taking a full breath or coughing, and by great tenderness on pressure. If it happens to be attended by slight febrile excitement, or by a cough, it is impossible to distinguish it from pleurisy, except by attending to the physical signs which characterize the latter disease. Cruveilhier maintains that 'pleurodynia is nothing more than adhesive pleurisy'; and in many cases of assumed pleurodynia, there is little doubt that the pain is due to old adhesions. The disease generally yields to local measures, such as blistering, or counter-irritation in a milder form by rubefacient liniments. A mixture of soap-liniment and chloroform rubbed over the affected part two or three times a day, often gives relief. In the more persistent cases, leeches may be applied with benefit.

PLEURONE'CTIDÆ, a family of fishes included in Cuvier's order *Malacopterygii*, but belonging to the order *Anacanthini* of Müller's system (see *MALACOPTERYGII*), and remarkable for a character to which there is nothing similar in any other vertebrate animals, a want of symmetry in the head, and for swimming not with the back uppermost, like other fishes, but with one side uppermost. The peculiar structure of the head adapts it to this mode of swimming, both eyes being on that side which is uppermost. Some of the bones of the head are distorted to a very considerable degree, but there is no want of symmetry in those of the body. The sides of the mouth are unequal. The body is extremely compressed, whence the P. are popularly termed *Flat Fish*, the back and belly being mere edges fringed by the dorsal and anal fins. The pectoral fins are generally unequal, also the ventral fins, those of the lower side being smaller than those of the upper. The upper side is often brown, or of some darkish color, and variously marked; the lower side whitish. The color of the upper

side generally corresponds so much with that of the bottom, close to which these fishes swim, that they readily escape observation; and on this they seem chiefly to depend for safety, although, when hard pressed, they raise themselves in a vertical position, and suddenly throw themselves upward and forward to some distance, but then resume their ordinary posture, and as close to the bottom as possible. Their ordinary swimming is by a kind of undulating movement. They swim with great activity. They have no air-bladder. They abound chiefly where the bottom is smooth, either muddy or sandy. All of them are sea-fishes, but some are very common in brackish water, ascend rivers, and can be kept in fresh-water ponds. Many of them are in great esteem for the table. The turbot, halibut, brill, plaice, and flounder are examples of this family.

PLEURO-PNEUMONIA, in an epizootic form, first appeared amongst the horned cattle of Great Britain and Ireland in 1841. From time immemorial it had, however, been known in the great cattle-breeding plains of Central and Northern Europe. It consists in a sub-acute inflammation of the structure of the lungs and their investing membrane, shows a great tendency to early exudation, and is accompanied by low fever. It is contagious, but, like many other contagious disorders, it occasionally occurs independently of contagion, and is fostered by overcrowding, exposure to cold and wet, damp, dirty hovels and other such causes, which depress the vital powers. The symptoms come on insidiously, appetite and rumination are irregular, there is fever, dulness, a short, half-involuntary cough, with quickened breathing and pulse. In cows, the yield of milk is early diminished. After three or four days, large portions of the lungs become filled with the products of inflammation, hence the labored breathing, quick indistinct pulse, wasting, and fatal weakness. Death generally occurs in from ten to twenty days. When pleuro-pneumonia first appeared in this country, it was greatly more fatal than it has since become, and fully four-fifths of the cattle attacked died; with prompt and rational treatment, more than one-half of the affected cases now recover. But as a favorable result is uncertain, and much flesh is lost even during a slight attack, it is still advisable, when pleuro-pneumonia breaks out in a herd, to consign to the shambles any of the cattle in good condition that have mixed with those diseased.

The best treatment consists in avoiding bleeding and all reducing remedies, supporting the strength, and keeping up the action of the skin, bowels, and kidneys, in order that the poisonous products of the disease may be rapidly got rid of. For this end, the patient should be provided with a cool comfortable house, clothing to the body, bandages to the legs, a daily dose of two ounces each of nitre and common salt given in treacle and water. When the bowels are costive gentle laxatives are required. By the second or third day, counter-irritants may be applied to one or both sides, which should first be bathed with hot water and thin mustard paste, or a mixture of cantharides and euphorbium ointments well rubbed in. By the third or fourth day, or earlier, if there is weakness, arrested secretion, and coldness of the skin, give several times daily some stimulant, such as a quart of warm ale, with an ounce or two of ginger or other stomachic, some good whisky-toddy, three-ounce doses of sweet spirit of nitre, or of spirit of ammonia. Whilst the disease continues, and even during early convalescence, all food requiring rumination must be interdicted, and mash, flour and treacle, bruised grain, or any light digestible articles substituted for the ordinary hay, straw, or roots. As pleuro-pneumonia is in many cases propagated by contagion, the sick should be separated from the sound stock; and any premises they have occupied carefully cleansed by whitewashing, and the use of McDougall's, Condy's, or other effectual disinfectants. When pleuro-pneumonia prevails in a neighborhood, all fresh purchases should be placed in quarantine, and kept perfectly away from the home-stock for at least three weeks. Attention to this simple precaution has preserved many farmers from pleuro-pneumonia, even while it has raged all around them.

PLEXI'METER. See PERCUSSION.

PLEYEL, IGNAZ, a musical composer of some note, born in 1757 at Ruppersthal, near Vienna. He studied music under Van-hall and Haydn, and made in early life an extensive tour in Italy, to hear the works of the best composers. In 1783, he was made *Capellmeister* of Strasburg Cathedral, and during the succeeding ten years, composed most of the works on which his popularity rests. In 1791, he visited London, and composed there three symphonies. Two years afterwards, during the frenzy of the French Revolution, he fell under suspicion, and in proof of his acquiescence in the new order of things, had to compose a musical drama for the anniversary of the 10th of August; which saved his life. After a long career in Paris as a publisher of music and pianoforte manufacturer, he retired to an estate which he had purchased near Paris, and died in 1831. His compositions, consisting of quartetts, concertantes, and sonatas, are full of agree-

able melodies, sometimes light and trivial, but occasionally vigorous.

PLI'CA POLO'NICA is the name given to a disease of the scalp, in which the hairs become matted together, by an adhesive and often fetid secretion, and which is especially prevalent in Poland, although it occasionally occurs in other countries. The hair is found, on microscopic investigation, to be invested with a fungus of the genus *Trichophyton*. The only treatment that is beneficial is the removal of the hair, and strict attention to cleanliness; but as it is popularly believed in Poland that this affection affords a security from all other sickness and misfortune, it is often difficult to persuade patients to have recourse to these means. For an account of the parasitic fungus that attacks the hair in this disease, and of the changes of structure which it induces, see Küchenmeister's *Manual of Parasites*, vol. ii. pp. 148—152.

PLINLI'MMON, or PLYNLIMMON, a mountain of Wales, on the boundary between Montgomery and Cardigan, 11 miles north-west of Llanidloes. It is 2481 feet in height. The name P. is said to be a corruption of the Celtic *Pumlumon*, signifying Five Rivers, and to be due to the fact, that five rivers have their source in this mountain: one of them is the Severn, and another the Wye. P. is a huge mountain mass, with three chief summits.

PLINTH, the square member at the bottom of the base of a column. Also the plain projecting band forming a base of a wall.

PLINY (C. PLINIUS SECUNDUS), often called Pliny the Elder, and author of the celebrated *Historia Naturalis*, was born in the north of Italy, either at Novum Comum (*Como*) or Verona, 23 A.D. Whether it was his birthplace or not, the former town was certainly his family's place of residence, since he had estates in its neighborhood; his nephew, the Younger Pliny, was born there, and inscriptions relating to members of his family have been found near it. While still young, he was sent to Rome, where his ample means and high connections secured him the best education. At the age of 23, he entered the army, and served in Germany, as commander of a troop of cavalry, under L. Pomponius Secundus, of whom, in later life, he wrote a memoir. He traveled over nearly all the frontier of that extensive province, visited the Cauca and the sources of the Danube, composed during the intervals of military duty his treatise *De Jaculatione Equestri*, and commenced a history (afterwards completed in twenty books) of the Germanic wars.

On his return to Rome in 52 with Pomponius; he entered on the study of jurisprudence; but his practice as a pleader proved him to have no great capacity for the legal profession; and accordingly, he retired to his native place, where he spent the greater part of the reign of Nero in miscellaneous authorship. It was during this period that he wrote his *Studiosus*, a treatise in three books on the training of a young orator from the nursery to his entrance on public life, and apparently intended to guide the education of his nephew; also his grammatical work, *Dubius Sermo*, in eight books. Shortly before Nero's death, we find him a procurator in Spain, where, in 71, he heard of his brother-in-law's decease, and of his being intrusted with the guardianship of his nephew, Pliny the Younger, whom he adopted on his return to Rome before 73. Vespasian, the reigning emperor, whom he had known while serving in Germany, received him as one of his most intimate friends; and it was at this period that he completed, in thirty-one books, and brought down to his own time, the Roman history of Aufidius Bassus. His mode of study at this time was a model of systematic assiduity. When living in the busy world of Rome, he would begin his studies by candle-light in autumn at a late hour of the night, and in winter at one or two in the morning. Before daybreak, he would call on the emperor, for whom he would proceed to execute various commissions; this done, he would return home, and resume his studies. A slender meal would follow; after which he would, in summer weather, lie in the sunshine, and take notes or extracts from the books which were read to him.

The practice of jotting down important facts or observations was habitual with him, and he was often heard to say that there was no book, however bad, from which some good could not be got. A cold bath, followed by a light meal and a short sleep, occupied another interval, after which he would study till the *cena*, or dinner-time. Even at this meal, some book was read to him, on which he would make comments. When in his country residence, he studied nearly all the time, except when in the bath; and even then, while his attendants were performing the duties incident to that luxury, he would be listening to some one who read to him, or he would be dictating to his amanuensis. When on a journey, again, he was never without a secretary at his elbow, provided with a book and tablets. By this mode of life, he collected an immense mass of materials, from which he compiled his great *Historia Naturalis*, published about 77. No fewer than 160 *volumina* of notes were found at his death, two years afterwards.

The great eruption which, in 79, submerged Herculaneum and Pompeii was at its height when he was stationed off Misenum, in command of the Roman fleet. Eager to examine the phenomenon more closely, he landed at Stabiae, where he was suffocated by the vapors caused by the eruption. He was, as his nephew tells us, corpulent and asthmatic, and sunk the more readily. None of his attendants shared his fate.

Of all his works, only his *Historia Naturalis* has come down to us. It comprehends a greater variety of subjects than we now regard as included under that title. Astronomy, meteorology, geography, mineralogy, zoology, botany, everything, in short, which is a natural or non-artificial product, finds a place in P.'s Natural History. Even to this elastic interpretation of the term, he by no means rigidly adheres; the work being interspersed with digressions on such subjects as human institutions and inventions, and the history of the fine arts. It is divided into 37 books—the first of them being a dedicatory epistle to Titus, with a table of contents of the remaining books, and embraces, as we are told in the preface, 20,000 matters of importance, extracted from about 2000 volumes. Its scientific merit is not great. There is little attempt at philosophical arrangement; the observations are nearly all taken at second-hand, and show small discrimination in separating the true from the false, or the probable from the marvelous. His meaning is often obscure, from his writing of things with which he was personally unacquainted, and from his having missed the true sense of the authors whom he cites or translates. But it cannot be denied that the work is a great monument of industry and research—most praiseworthy as having been constructed and completed amid the labor of other onerous undertakings, and amid the distractions of a life engaged in active official employment; and most valuable as supplying us with details on a great variety of subjects, as to which we have no other means of information. The best critical editions of the text are those of Sillig (8 vols. 1851-57), Ian (1854-63; new ed. 1875), and Detlefsen (1867-75). There are several editions of the text with French notes, one by Grandsagne, with notes by Cuvier and others (1829), and one by Littré (1848-50). Pliny's work has been translated into almost all European languages.

PLINY (C. PLINIUS CÆCILIVS SECUNDVS), nephew of the preceding, and son of C. Cæcilius, frequently called Pliny the Younger, was born at Novum Comum, 61 A.D. He was still young when he lost his father, and was adopted by his uncle, under whose care, and that of his mother, Plinia, and his tutor, Virginius Rufus, his education was prosecuted. Passionately devoted to literature, he wrote a Greek tragedy at the age of 13; studied eloquence under Quintilian; and became so famous for his literary accomplishments, that he acquired the reputation of being one of the most learned men of the age. His oratorical powers were also considerable; in his 19th year, he began to speak in the forum; and his services as an advocate before the court of the Centumviri and the Roman senate were in frequent request. He held numerous official appointments; served, while a young man, as *tribunus militum* in Syria, where he listened to the teachings of Euphrates the Stoic, and Artemidorus; was afterwards *questor Casariæ*; was prætor about 98, and consul in 100, when he wrote his *Panegyricus*, an adulatory eulogium of the Emperor Trajan, and containing little information as to the author and his times. He was appointed in 103, prætor of the province Pontica, an office which he vacated in less than two years; and he also discharged the function of curator of the banks and channel of the Tiber. He was twice married, his second wife being Calpurnia, grand-daughter of Calpurnius Fabatus, and considerably younger than her husband, by whom she was much beloved for her accomplishments and amiability. He had no issue by either marriage.

Our knowledge of P. the Younger is mainly derived from his letters or *Epistolæ*, of which there are ten books. He collected them himself, and probably wrote many of them with a view to publication. They hold a high place in epistolary literature, and give us many interesting glimpses into the life of their author and his contemporaries. P. himself appears in them to considerable advantage, as a genial and philanthropic man, enamored of literary studies, and fond of improving his estates by architectural ornament. His ample fortune was liberally bestowed; and his slaves always found in him an indulgent master. Infirmary health impaired throughout life his constitution, which was naturally weak; but of the time or cause of his death, we know nothing. Of the facts contained in his letters, however, the most interesting to us are those relating to the punishment of the Christians. Death appears to have been the penalty attached even to the confession of being a Christian; although the adherents of the faith admitted no other acts, on examination, than those of meeting on a fixed day before dawn, when a hymn to Christ was sung, and taking an oath to avoid theft, adultery, breach of faith, and denial of a deposit. Nothing more unfavorable to them than this could be extorted by P. from two female slaves, reputed to be deacon-

esses, whom he put to the torture. P. having asked Trajan how he was to stop the spreading superstition, the emperor replied that no general rule could be laid down; that he ought not to institute a search after persons supposed to be Christians; but if any were brought before him, and the charge was proved, such were to be punished, if still impenitent. The best edition of P.'s *Panegyricus* and *Epistolæ* together, is that of Schæfer; of the *Epistolæ* alone, that of Gierig.

PLUCA'RIA, a genus of *Alga*, of the order or suborder *Ceramiacea*, having a cartilaginous frond, composed of large cells, as if jointed, and dividing into slender, tufted, and densely aggregated branches. *P. helminthochorton* is the CORISCAN MOSS of the apothecaries' shops, once of some reputation as a vermifuge but now little used, and believed to be of little efficacy. It is a small plant, with a filiform entangled frond, and grows on the shores of the Mediterranean. It has a strong marine odor and a salt taste. It consists in great part of a vegetable jelly or mucilage, which renders it nutritious, and contains much chloride of sodium, sulphate of lime, and carbonate of lime. As sold in the shops, it is always much mixed with other algæ.—*P. tenax* is a small plant with filiform, branched, and somewhat gelatinous frond, much used by the Chinese as a glue. It is also used in China as an article of food.—*P. candida* is used to a considerable extent as an article of food in the East. It is popularly called CEYLON MOSS. The frond is whitish and much branched, the branches long and somewhat clustered. It is exported to China from the islands of the Indian Archipelago, forming a portion of the cargo of almost every junk. The Chinese make it into a jelly with sugar, and use it as a sweetmeat. It consists in great part of a vegetable jelly, with a considerable quantity of starch. It has been introduced into Britain as a light and nourishing food for children and invalids, and is found particularly suitable in cases of irritation of the mucous surfaces.

PLUCE'US. See WEAVER BIRD.

PLOCK (Russ. Plotzk), a town of Poland, capital of the government of the same name, occupies an elevation on the right bank of the river Vistula, 78 miles west-north-west of Warsaw. Its principal buildings are the cathedral, built in 961, the bishop's palace, theater, &c. Agriculture, and the export of grain to Danzig and other ports, are the chief employments. Pop. (1880) 22,127.

PLOCK (Russ. Plotzk), a government in the north of Poland, bounded on the north by Prussia, and on the south-west by Warsaw. Area, 5520 sq. m.; pop. (1880) 522,006, 80 per cent. of whom are Poles. Hills occur in the north and on the banks of the Narew and Vistula, which with the Bug are the chief rivers. One-third of the surface is covered with forests, and there are many marshes and lakes. The inhabitants are engaged chiefly in agriculture, and in cattle and sheep breeding.

PLOJE'SHTI, or PLOYESTI, a town of Walachia, 35 miles north-by-east from Bucharest. It is a place of considerable trade, and has a great annual wool-fair. Pop. (1880) 33,000.

PLONGÉE, in Artillery and Fortification, means a slope towards the front. Thus, in speaking of the course of a shell through the air, its plongée is from the point of greatest altitude to the point at which it strikes the earth. So, in fortification, the plongée is the top of the parapet sloping gently towards the front. The slope is ordinarily 1 in 6; but a deviation is permissible of from 1 in 9 to 1 in 4; the sharper the slope, however, the more liable is the crest of the parapet to be destroyed by an enemy's fire. Moreover, as flat a plongée as possible is desirable, that sandbags may, when required, be laid upon it to form a cover for riflemen. See FORTIFICATION, fig. 7.

PLOTINUS, the most original and important philosopher of the Neo-Platonic School, was born at Lycopolis in Egypt 205 A.D.; but such was his utter indifference to things human, 'being ashamed almost to live in a body,' that he never would divulge even his parentage. He would never allow his birthday to be celebrated, although he gave feasts on those of Socrates and Plato; nor would he ever permit a painter or sculptor to perpetuate his features, or, as he called it, to produce the image of an image—the body being to him only a faint image of existence. He deemed it tedious enough already to have to drag about this image whithersoever he went in this life. His body was altogether contemptible in his eyes; he would see no physician in his illness, and was very sparing in the use of food, refraining from meat, often even from bread. Strangely enough, his desire for the study of philosophy did not arise within him before his 28th year, when he repaired to Alexandria, and there, after having sat at the feet of the great masters for some time without feeling satisfied with their teachings, he at last became acquainted with Ammonius Saccas, and in him found the desired teacher. For ten years he zealously attended his lectures, and although he had agreed, with two of his fellow-students, never to make known aught of Ammonius's teachings to the world, he yet became the chief representative

and author of that school, less as a pupil than as an independent thinker, who taking his stand upon its theorems, developed them to their full extent. In 242 he joined Gordianus's expedition to Persia, in order to devote himself to the philosophy of India and Persia; but the emperor being murdered in Mesopotamia, he had to repair hurriedly to Antioch, whence, in 244, he went to Rome. His lectures here were attended not only by crowds of eager youths, but men and women of the highest circles flocked to hear him.

Not only Platonic wisdom, in Neo-Platonic garb, but asceticism and the charm of a purely contemplative life, were the themes on which he, in ever-new variations, and with an extraordinary depth and brilliancy, held forth; and such was the impression his earnestness made upon his hearers, that several of them really gave up their fortune to the poor, set their slaves free, and devoted themselves to a life of study and ascetic piety. Dying parents intrusted their children and money to him, well knowing that an honest guardian, and one more anxious for his charges, could not be found. It is hardly surprising to find that his contemporaries coupled with his rare virtues the gift of working miracles. Sixty years old, he thought of realizing Plato's dream, by founding an aristocratical and communistic commonwealth like the latter's 'Republic'; and the Emperor Gallienus was ready to grant the site of two cities in Campania for his 'Platonopolis'; but his courtiers prevented the fulfilment of this promise. P. died from a complication of diseases, in 270, at Puteoli, 66 years of age.

Although he began to write very late in life, he yet left 54 books of very different size and contents. His MS. being very carelessly written, he asked his pupil Porphyry to revise and correct it for him. The latter also divided it into six principal divisions, each subdivided again into nine books or *Enneads*. The most important parts are those which treat of Beauty, Fate, Immortality of Soul, the Good or One, the Three Original Substances of Free Will, against Gnostics of Providence, of the Genesis of Ideas, of the Influence of the Stars, of the Supreme Good, &c. The language is very unequal in the different portions, according to the mood and circumstances to which they individually owe their existence; but it always is original, compact, and graphic in the extreme.

P.'s system was based chiefly on Plato's theorem of the Ideas; only that while Plato assumed the Ideas to be the link between the visible and the invisible, or between the Supreme Deity and the world, P. held the doctrine of Emanation, that is, the constant transmission of powers from the Absolute to the Creation, through several agencies, the first of which is 'Pure Intelligence,' whence flows the 'Soul of the World,' whence, again, the souls of 'men' and 'animals,' and finally 'matter' itself. (For a fuller account of this part of P.'s system in its historical connection, see NEO-PLATONISTS.) Men thus belong to two worlds, that of the senses and that of Pure Intelligence. It depends upon ourselves, however, to which of the two worlds we direct our thoughts most and belong to finally. The ordinary virtues, as justice, moderation, valor, and the like, are only the beginning and very first preparation to our elevation into the spiritual realm; purification, or the exercise of *purifying* virtues, is a further step, to which we attain partly through mathematics and dialectic; and the abandonment of all earthly interests for those of intellectual meditation, is the nearest approach to the goal. The higher our soul rises in this sphere of intellect, the deeper it sinks into the ocean of the good and the pure, until at last its union with God is complete, and it is no longer thought but vision and ecstasies which pervade it. These are a few snatches of P.'s philosophical rhapsodies, to which may be further added his mysterious belief in a kind of metempsychosis by which souls, not sufficiently purified during life, return after death, and inhabit according to their bent, men, animals, and even plants.

He further held views of his own respecting gods and demons, whom he divided into different classes, according to their degrees; and professed faith in Mantic, astrology, and magic, the conviction of the truth of which sciences he derived from his theory of the harmony in the intellectual world, reflected by the material world. Yet it is clear from his dicta on these subjects that he did not believe in these so-called sciences in the gross sense of the herd, but that he had a vague knowledge of those mysterious laws of attraction and repulsion which go through nature. P.'s philosophy, which, as it were, tried to combine all the systems of Anaxagoras, Parmenides, the Pythagoreans, Plato, and Socrates, and the Stoa into one, was the last and boldest attempt of the ancient Greek world to explain the mystery of the creation and of existence. Its influence upon modern philosophy is remarkable. From Spinoza to Schelling, the reminiscences of P., irrespective of the drift of particular parts of their systems, recur constantly.

P.'s works were well-nigh forgotten, when Marsilius Ficinus first published a Latin paraphrase of them (Florence, 1492), which was followed by the *Ed. Pr.* of the original (Basel, 1580 and

1615). The first critical edition, however, is due to Creuzer (Oxford, 1835, 3 vols.). Others are those of Dübner (Paris, 1855) and Kirchhoff (1856). Parts of his works were translated into German by Engelhard (1820); into English by Taylor (1794 and 1817); into French by Bouillet (1861, 3 vols.). See Kirchner, *Die Philosophie des P.* (1854).

PLOUTUS. See DARTER.

PLOUGH, PLOUGHING. The first in order and importance of agricultural operations is the breaking up of the soil, and this is accomplished, in all countries where agriculture is in an advanced state, by inverting the upper stratum of earth upon which the plants grow. Such a mode also buries and destroys all weeds, leaving the surface clean and unencumbered. The inversion of the upper stratum is effected by turning over successive sods or slices, of the length of the field, and of varying thickness and depth, according to the nature of the succeeding crop, and the nature of the soil; and the implement employed for this purpose is the *plough*. The general form of the plough is known to every one, and to the unobservant eye, it appears to be a very simple and even primitive tool; nevertheless, much mechanical skill and ingenuity have been expended in perfectly adapting it to its work. It is a combination of instruments (fig. 1) fastened to a beam,

Fig. 1.

GBL; the coulter, K, is an iron knife-blade, for cutting the sod vertically; the share, CFD, which is merely a socket fitted on and not fastened to the body of the plough, has a sharp point, C, and a projecting horizontal edge, CO, on its right-hand side, its part of the work being to separate the under-surface of the sod from the subsoil; by means of the mould-board, H, the slice, now wholly separated from the firm ground, is raised up and turned over by the forward motion of the plough; and the stiles, or handles, one of which, BL, is a continuation of the beam, the other, M, being fastened partly to the former by rods, and partly to the lower portion of the framework (fig. 2, which also

Fig. 2.

shows the point of the plough with the share removed), are for the purpose of guiding the implement.

The front part of the beam is formed with an upward curve; at its extremity, is placed the *bridle*, N, to which the horses are attached by means of swing-trees and chains or traces, and the object of which is to enable the workman to elevate or depress the line of draught, or move it to the right hand or the left, as may be found necessary. The left sides of the coulter, share, and framework ADEB, should evidently be in the same vertical plane. The form of the mould-board is of the utmost importance, and has chiefly attracted the attention of agricultural machinists since the time when improvements on the plough were first projected. Its office being to raise and turn the sod, it is necessary that the surface should slope upwards and outwards from the front, so as to apply a pressure in both directions, and, accordingly, the surface is so shaped that from the point of the share, where it is horizontal, it gradually curves upwards, till, at the extremity, P, it inclines over away from the body of the plough. The gradual change produced on the position of the furrow-slice is seen in fig. 3, where ABCD on the left-hand side, represents the slice un-

Fig. 3.

touched by the plough, AD being the line of section by the coulter; DC, by the share; BC, the open slice from which the previous furrow (E) to the right-hand side has been separated; and

the four successive rectangles, ABCD to the right, illustrate the successive changes of position of the furrow as the mould-board is pushed forward under and on its left side, till it is finally left, as represented in ABCD on the right hand; E, F, G are furrows which have previously been laid in their proper position. The advantages of laying the furrows in the position shown are these: in the first place, the weedy side of each furrow being closely applied to the previous furrow, and kept pressed against it by its own weight, and the pressure of the mould-board, the weeds are completely buried; secondly, the ridged surface thus presented, affords the means of covering the seed by harrowing; and lastly, the openings below increase the amount of surface accessible to air, and drain off superfluous water.

The modern plough is wholly formed of iron; the share and the framework of malleable, and the mould-board of cast iron, or sometimes of steel; while the coulter is frequently welded with steel on the right-hand side, the better to resist attrition. In most of the English (as distinguished from the Scotch) ploughs, wheels are attached at or near the front end of the beam, a contrivance which renders the implement more steady in its motion, more easily managed, and capable of doing better work in the hands of an inferior workman; but it is generally believed, in Scotland at least, that the plough without wheels, or *swing-plough*, as it is technically termed, is greatly more efficient in the hands of a thoroughly skilled ploughman. The usual dimensions of the furrow-slice in lea or hay-stubble are 8 or 9 inches in breadth by 6 in depth; and in land for green crop, 10 inches in breadth and 7 or 8 in depth. Shallower ploughing is not unfrequently adopted, especially on thin soils, and in various parts of England. Nor is it uncommon to plough stubble-land 10 inches or more in depth.

Other kinds of ploughs are used for special purposes, such as *trench-ploughs*, which are made on the same principle as the common plough, but larger and stronger, so as to bring up a portion of the subsoil to the surface; *subsoil ploughs*, which have no mould-board, and merely stir and break up the subsoil, thus facilitating drainage; *double mould-board ploughs*, which are merely common ploughs with a mould-board on each side, and are employed for drilling turnip or potato land, for water-furrowing, and for earthing up potatoes, &c. Of each of these ploughs, there are many varieties, each maker having generally some peculiar views regarding the form and proportion of some parts of the instrument. For those who wish to study minutely the best form of plough, it will be necessary to consult works on agriculture and agricultural implements.

There is, however, one very peculiar form of plough sometimes used in various parts of England, which deserves more particular notice; this is the *turn-wrest plough*. Its chief peculiarity is, that instead of one, it has two mould-boards, one on each side, and these are alternately brought into operation, so that the furrow is always turned over in the same direction. The mould-boards are firmly fastened together in front, and kept at a constant distance from each other behind, by means of struts, while the handles are movable with reference to them; the mould-board which is intended to be used being pushed away from, and the other (which for the time does the same work as the vertical surface ADEB in fig. 1) brought nearer to the line of the beam; of course, when the next furrow is ploughed, the mould-boards exchange adjustments. This form of plough is useful in ploughing along a hill-side, as by it all the furrows can be turned over towards the hill, thus preventing the natural tendency of the soil to work itself downwards, leaving the upper portions bare. The form (fig. 4)

Fig. 4.

here given is the rudest and least desirable form of the turn-wrest; it is that which is used in Kent, and there esteemed. Some years ago the *double-furrow* plough was introduced. It consists of an iron frame, similar in some respects to that of a grubber or cultivator, with two breast-plates, mould-boards, and shares; the one set a little back from the other, and so far distant as it is desired should be the width of the furrow. Two or three wheels bear the implement—one in front running in the bed of the last excavated furrow, and the other one or two behind. There is a directing rod, but no stilts. The double-furrow plough was at first singularly popular, and after a few years was found on almost every farm. It was, however, soon found that, generally speaking, the weight was too much for the draught of a pair of horses, and that, even on light land, three horses were required. In fact, the

depth of tillage is in practice gradually increasing; so that, unless for a grain crop after either turnips or potatoes, these ploughs have been nearly laid aside.

The operation of ploughing can only be briefly referred to. Wherever the soil has been efficiently drained, the ridges can be made wider and ploughed on the flat, high ridges being no longer necessary for carrying off the water. There are advantages in ploughing the land in uniform ridges of 18 feet wide, or with an open furrow not more than 72 feet apart, made as flat as possible. But the effects of cultivation by steam show that the fewer the open furrows the better, particularly when the land is intended for a grain crop which is to be sown by drill or broadcast with machinery, and when the crop is to be cut with a reaping-machine, as is now almost universally the case. It is curious to notice how one improvement in farm practice leads on to another. The most common mode of ploughing with horses is now simply by casting the soil two ridges in and the next two out, beginning always with the two ridges where last time was left the open furrow.

The term *feeling* is applied to the commencement of a wide-ridge. The process of feeling differs according to the state of the land to be turned over. If there exists an old furrow or hollow, as is generally the case in lea, two shallow furrows are turned, the one against the other, and so on; along each side of this commencement the plough moves, adding furrow after furrow, and increasing in depth until the third or fourth round is reached. This constitutes what is technically called the gathering system. In newly cleaned land, or where a hollow does not appear to turn the first furrows into, two furrows are thrown out and then turned lightly in. The most common system, however, is what is known as *casting or cleaving*. That is, after one feeling is accomplished, another is made at the other side of the ridge, and furrow after furrow is turned towards the inside of each of these feelings until the whole ridge is ploughed, and then in the center is formed the *finish or mids*—a furrow or trench into which the feeling is turned the next time the land is ploughed.

The plough is one of the most ancient of implements, and is mentioned in the Old Testament at a very early period, iron shares being also incidentally noticed more than seven centuries B.C. The ancient Egyptian plough was wholly of wood, and in some instances consisted of little more than a pointed stick, which was forced into the ground as it was drawn forward. In fact, the earliest ploughs were neither more nor less than varieties of the *Hoe* (q. v.), worked by pressing the point into the ground instead of by percussion. The earliest form of the Greek plough, the *autogon* (fig. 5, a), is an example of this; it was merely the trunk

Fig. 5.

1, the Mysian plough; 2, its pole, where the oxen are attached; 3, shares of various forms; 4, the tail or handle; 5, the yoke; a, early Greek plough.

of a small tree, which had two branches opposite to each other, one branch forming the share and the other the handle, while the trunk formed the pole or beam. The more improved form, the *pektion*, in use among the Greeks, was not substantially different from the modern form in use in Mysia (fig. 5.). The ancient Egyptian plough in one of its early stages is represented in fig. 6.

Fig. 6.

and, like the two forms above described, is devoid of all apparatus enabling the laborer to guide it, all that he can do being to press (by his weight applied to the handle) the share into the

earth. The Egyptians, however, gradually improved the form, till it assumed the appearance of a hollow wedge formed by the two handles joined at the bottom, and with the beam fastened between the handles a little above their point of junction.

Fig. 7.

The Romans, an essentially practical nation, largely improved on the plough, adding to it the coulter and mould-board, and occasionally attaching wheels to the beam to prevent the share from going too deep into the earth (fig. 8). The plough was almost

Fig. 8.

unknown among the American aborigines, though Prescott describes a mode of ploughing practised among the Peruvians, which consisted in the dragging forward of a sharp-pointed stake by six or eight men, its sharp point, which was in front, being kept down in the ground by the pressure of the foot of another man who directed it. Britain and America, and their colonies, are the only countries in which the plough has been brought to a state worthy of being considered effective, and even in Britain the most important amendments on it are not two centuries old. England took the lead in improvement by rendering the form more neat and effective, and by attaching wheels to aid in keeping the plough in a proper upright position. In Scotland, for some time after this, the plough was extremely rude and cumbersome, and usually drawn by 8 oxen, and some wooden ploughs are in use yet in the Highlands of Scotland. In the middle of the 18th c., some Dutch ploughs were imported, and being found more effective, an impetus was thus given to attempts at improvement. James Small, who may justly be regarded as the real inventor of the Scotch or swing plough, made great and important changes in the form and efficiency of the coulter, share, and mould-board, producing an implement at once lighter and vastly more efficient. All the swing-ploughs of successive makers are founded upon the basis of Small's plough. Wilkie of Uddingston (Lanarkshire) formed it wholly of iron, and his modification has been universally adopted in the modern ploughs.

Among the various improvers of this form of cultivator may be mentioned, besides Wilkie of Uddingston, Gray of the same place, Clarke of Stirling, Cunningham, Barrowman, Ponton, Sellars, Huntly (who have sent many of the swing-ploughs, for which their firm has long been famous, to Australia). In England, the improvers have chiefly been Ransomes of Ipswich (the patentee in 1785 of the cast-iron share), Howard of Bedford, Hornsby of Grantham (Lincolnshire) and Bushby of Bedale, the last of whom gained a medal for his mould-boards at the Great Exhibition of 1851. For further information concerning the plough and the mode of using it, see Morton's *Cyclopædia of Agriculture* (1856), Stephens' *Book of the Farm, Book of Farm Implements*, by Henry Stephens and R. Scott Burn, and other works.

Steam-ploughing.—Although it is not yet a quarter of a century since cultivation of the land by steam came into successful operation, it is about two centuries and a half ago since it was foreseen to be possible. So long ago as 1618, David Ramsey and Thomas Wildgosse took out letters-patent for engines and machinery to plough the ground without the aid of oxen or horses; and nine years afterwards, other ingenious men obtained

letters-patent for machines to affect a similar purpose. It is the opinion of Mr. Woodcroft of the Patent Office, who compiled the *Abridgments of the Specifications Relating to Steam-culture*, that steam was the motive power intended to be employed; but as the first patent was taken out nearly 40 years before the Marquis of Worcester described the steam-engine in his *Century of Inventions*, the grounds for such an opinion do not seem quite satisfactory. In 1769, however, after the steam-engine had been applied to other purposes, there was lodged in the Patent Office a specification for a new machine or engine, to plough, harrow, and do every other branch of husbandry, without the aid of horses. The patentee was Francis Moore; and so confident was he of the merits of his plan, that he sold all his own horses, and persuaded his friends to do the same; 'because the price of that noble and useful animal will be so affected by the new invention, that its value will not be one-fourth of what it is at present.' Moore, however, was much too sanguine; his method of cultivating the land without the aid of animal power failed, as those of others before him had done.

The next invention necessary to mention was one by Major Pratt, patented in 1810. His plan was to have two engines, one on each headland, drawing, by means of an endless rope, an implement between them. In order to save the labor and loss of time in turning the plough at the ends, he attached two ploughs, back to back, making them work upon a fulcrum in the center of a frame, so that one could be raised out of the ground when the other was working. This was the first adoption of the balance-principle, now employed in most implements used in steam-cultivation. Major Pratt's apparatus, like those of his predecessors, never came into practical operation.

In the interval between 1810 and 1832, when Mr. Heathcoat, M.P., a Tiverton lace-merchant, patented the first steam-ploughing machinery that ever wrought successfully in the field, there were many inventions, but these being of little utility, need not be particularized. Mr. Heathcoat's machinery was principally intended for draining and breaking up soft or swampy land. It consisted of a locomotive steam-engine, with a broad, endless, flexible floor or railway attached to the wheels, so as to prevent them from sinking in the boggy soil. Opposite to this engine, an auxiliary carriage was placed, and between the two the plough was drawn backwards and forwards by an endless chain or band—engine and carriage moving along as the work proceeded. In 1836, this plough worked with tolerable success in Red Moss in Lancashire, and in 1837 it was tried near Dumfries, under the auspices of the Highland and Agricultural Society of Scotland; but here its performance, though in some degree satisfactory, was not sufficiently so to warrant the judges in awarding to it the prize of £500, which had been offered for the first successful application of steam-power to the cultivation of the soil by the Society. The apparatus was very cumbersome and expensive to work, the engine being 25 horse-power, and the number of men and boys employed in the operation no less than ten. The amount of work done was at the rate of 8½ acres per day. Mr. Heathcoat abandoned the machine after having spent about £12,000 on it.

After Mr. Heathcoat, the inventors specially worthy of mention are Alexander M'Rae, who, arranging his motive-power in the same manner as Major Pratt, made the important addition of a barrel to the plough-frame upon which the slack-rope was to be wound up; Mr. Hannam of Burcote, who, in 1849, designed an apparatus to be driven by an ordinary portable engine, to be stationed at the corner of the field, which was surrounded with wire-ropes in the same way as will be afterwards described in Howard's method; and Mr. Tulloh Osborn, who, in 1846, patented a plan for two engines running opposite each other on the headlands, having two drums fixed to them, one for the winding of the tight, and the other for letting out the slack, gear. This apparatus was tried by the Marquis of Tweeddale for some time at Yester; but it was found, in consequence of the great power required, and other effects in detail, to be very expensive, and was ultimately given up. To the Marquis of Tweeddale, therefore, belongs the honor of being the pioneer of steam-cultivation in Scotland.

In 1855, the Messrs. Fiskien of Stamfordham, Newcastle-upon-Tyne, took out a patent for a much more perfect apparatus for cultivating the land by steam than any that had previously appeared. The power was transmitted by a stationary engine to a hempen rope (the Messrs. Fiskien being anxious to dispense with wire-ropes), which was worked at a high velocity, and, passing round pulleys on two self-moving anchors, turned a drum upon the plough, whose revolution imparted motion to the implement upon which it was fixed. The important features in this system were the self-propelling anchors, the arrangement of the ploughs on the balance-principle, and the mode of steerage. This plough was exhibited at the annual show of the Royal Agricultural Society of England in the year the patent was taken out, and excited great interest, but failed to obtain any award. Three years before

this, the Highland and Agricultural Society of Scotland had thought so hopefully of the idea, that a grant was voted out of its funds to assist the author in maturing his project.

In 1854, Mr. Fowler exhibited his patent steam-draining appa-

ing implements also by means of wire-ropes. The first two principles have been mostly abandoned—the one on account of the great consumption of fuel, and the large amount of wear and tear occasioned to move the engine over uneven and soft ground;

Fig. 9.—Fowler's Steam-engine.

ratus at the Lincoln meeting of the Royal Agricultural Society of England; and from this time may be dated the practical history of cultivation of the land by steam; for the idea that such an apparatus could be wrought advantageously in other field-operations entered the mind of a practical farmer, Mr. Smith of Wool-

and the other, on account of the expense necessary to lay down rails over a farm. The only two systems in practical operation are what are called the direct and round-about—the former where the pull of the implement is directly to and from the engine; and the latter where the implement is drawn at right angles.

Fig. 10.—The Anchor.

ston, near Bletchley; and under the direction of Mr. Fowler, he got constructed an apparatus, which, with modifications, he worked successfully.

The best known of these methods are Fowler's and Howard's, though, perhaps, Smith should be credited with the round-about system, but Howard's name is now much more generally given to it.

The inventions since that time need not be enumerated. It

Fig. 11.—Fowler's Plough.

may be stated generally that they have included plans for engines traveling over the surface of the ground, drawing ploughs or other cultivating implements along with them; engines work-

Fowler's system we hope to make intelligible by the aid of cuts. The principal elements are an engine, an anchor, a wire-rope, and a balance-plough. In commencing operations, the engine is

Fig. 12.—Fowler's Anchor, Engine, and Plough at work.

ing on tramways, and drawing implements after them; engines moving along opposite headlands, and working implements between them by means of wire-ropes, and stationary engines driv-

placed at the end of one of the headlands of the field, and directly opposite it on the other headland is placed the anchor. Beneath the engine there is a large sheave or drum, five feet in diameter,

the groove of which drum is composed of a series of small leaf-like pieces of chilled cast-iron, each moving independently upon its own axis. The object of these is to prevent the rope from slipping (which it is apt to do in a plain groove under great strain), and this they do in a very ingenious manner, by closing on the rope as soon as it takes the bend—that is, as soon as the rope presses upon them—and they in the same manner open and release it immediately on the pressure being removed, or, in other words, as soon as the rope resumes the straight on the other side of the sheave. The position and nature of this drum on the engine will be understood by the accompanying cut. The anchor, as will be seen from the engraving (fig. 10), is a massive square framework of wood, mounted on six sharp disc wheels, each about two feet in diameter, which cut deep into the ground, and on the lightest land they take such hold as effectually to resist the pull of the rope which is passed round the sheave beneath. The anchor has a self-acting motion—the power being communicated

man at the engine, another on the plough, a third at the anchor, and the lads to look after the rope-porters. The water and coals needed for the engine must be brought by other men.

The plough-bodies can be removed from the frame, and in their place 'digging-breasts' be attached, by means of which the land is thrown up in a somewhat similar manner to that in which it is turned over by the spade. The price of the ploughing and cultivating apparatus is about £900.

At the Newcastle show of the Royal Agricultural Society, in July 1864, Mr. Fowler introduced two engines of 7-horse power, working simultaneously on opposing headlands. The expedition with which these engines were set down to and completed their work was a matter of admiration to all present, and the subject of special remark by the judges. These gentlemen say: 'The engines worked smoothly; and so far as we could ascertain, appeared to bear an equal share of work in either direction.' They got up steam in nearly half an hour less time than the 14-horse engine,

Fig. 13.—Howard's General Plan.

from the engine through the medium of the ploughing-rope—which enables it to move along the headland, and keep opposite to the engine.

The plough (fig. 11) is a framework of iron, balanced upon two large wheels. To each side of this framework there are attached four plough-bodies and coulters, so that four furrows are cut at one 'bout,' and the headland on which the anchor is stationed being reached, the end of the beam that was out of the ground is depressed (the other, of course, being raised), and the four plough-bodies that were out of the ground, and which point in the opposite direction, are inserted in the soil, and turn up the furrows on the way back to the engine. By altering the position of the plough-bodies along the frame-work, a broad or a narrow furrow can be cut at pleasure. In ordinary working, an acre an hour is accomplished. The wire-rope, by which the plough is dragged through the land, passes round the sheaves on the anchor and the engine, the ends are attached to two drums upon the plough, and by a nice mechanical arrangement, the ploughman who rides upon the implement is enabled to wind up, or let out slack if necessary, without loss of time. The wire-rope is made in lengths, which are easily disjoined, in order that it may be adjusted to irregularly shaped fields, or rather to

and working with them, much less time was required to arrange the tackle. 'The engines were masters of their work; and acting in combination, appeared to possess more power than the large engine and anchor. . . . The advantages of this system appear to be, that horses are not required to move tackle; that there is a saving of time in setting down, taking up, and removing from field to field [no unimportant consideration]; and that the two small engines are both available for ordinary farm-work, such as thrashing, driving, barn-work, &c.' The cost of the two engines, with the whole apparatus, ranges from £1200 to about £1500, according to the power of the engines, &c. The number of hands employed is the same as at the large anchor and engine; but as a skilled laborer is necessary, where only an unskilled laborer is needed in the latter case, the cost per day is 2s. more. Fowler has been very successful in gaining prizes for steam-ploughs, having won several thousand pounds in this way since 1856.

Howard's earliest system consists in a stationary engine driving a windlass, having two winding drums, with direct and reverse action, placed in front of it, round which is coiled about 1600 yards of wire-rope. By a simple lever movement, the man can drop the winding drums out of gear in an instant, a contrivance which enables him to attend to the proper coiling of the rope,

Fig. 14.—Howard's Plough.

fields that are not exact squares or parallelograms; for Fowler's method is not well adapted to such irregularities as prevent the engine and anchor being opposite each other. The rope is borne off the ground—a very necessary precaution, without which the wear and tear would be alike annoying and expensive—by a number of pulleys, or 'rope-porters' as they are called, mounted on frames. The outside ones, that is, those farthest from the work, are moved along by the action of the rope; those in front of the plough are removed by boys, and placed behind the implement as it proceeds. The *modus operandi* will be patent at a glance, from the annexed plan of working (fig. 12). To manage this apparatus three men and two boys are required—namely, a

and also to arrest, in case of accident, the plough in a moment, without stopping the engine. The engine is usually placed at the corner of the plot to be ploughed, the rope is carried round the field on rope-porters, and fixed at the corners by light anchors. A snatch-block placed in front of the windlass prevents the slack-rope running out too fast, and trailing on the ground. The plan of working given clearly illustrates the arrangement (fig. 13). The plough, as will be seen from fig. 14, is composed of two strong iron frames balanced upon four wheels, and crossing each other at their inner ends, thereby decreasing the length of the plough, and, as a matter of course, the breadth of the headland. The frames are raised and lowered in such a manner that the set

of ploughs out of work is independent of, and has no tendency to weigh or raise out of the ground the set in work. The frames are made for two, three, or four furrows, and 'diggers' or scarifiers can be attached as in the case of Fowler's. The latest improvements of a material character on the Bedford firm's steam-ploughing tackle consist of a patent self-coiling windlass and universal joint, 1600 yards of steel rope, patent 5-tined self-lifting cultivator, 2 self-moving anchors, &c. Two men and two boys are sufficient to work the set with a 12 horse-power patent ploughing and traction engine; the cost of the set is £1000. This recently introduced apparatus is very popular, and promises to be extensively employed.

Howard's double-engine system is specially adapted for letting out on hire, for large farms, and for use on the great foreign plains. The engines are placed on opposite headlands, and work a plough, grubber, or cultivator between them, similar to the principle on which Fowler's double-engine system operates. Three men and two boys are required to the working of this set. The price of a pair of 12-horse patent ploughing and traction engines, each with winding drum, together with 800 yards of steel-wire rope, and 6 rope-porters, is £1350.

In the course of the last few years, the Messrs. Howard have issued several hundred sets of steam-cultivating tackle. The Messrs. Howards' cultivator was more generally used for some time than the plough, but the mere digging of much of the land for corn, as a substitute for ploughing, was attended with disappointment; so the plough has been all but universally adopted for soil intended for grain crops.

The Fiskien tackle is used to a considerable extent in various parts of the country, generally with the plough emanating under that name, and sometimes attached to three-furrow ploughs made by local manufacturers. Several of the other famed firms dispose of parts of the complete set separately. In other words, those who buy the engines and gearing do not in every case purchase the plough from the same company.

In Coleman's system, the drums upon which the rope is wound are attached to the sides of the engine, and give out and take on rope alternately. The engine moves along the headland; and the anchor, upon which there is very little strain, and which is, therefore a very light, portable article, is shifted opposite to it by a man as the work is performed; direct action being obtained here, as in the case of Fowler's. The peculiarity of the plan consists in having two implements instead of one at work, the implements being grubbers, which smash up the ground—a practice adopted by some farmers in England, in preference to turning the sod over with the plough. On commencing operations on this plan, the field is divided into two equal parts. The cultivators or grubbers work only one way—towards the engine. They are attached by the front to each end of a strong wire-rope, while a smaller wire-rope is fastened to their rear. The one cultivator is placed at the far side of the field where its teeth or 'tines' are inserted in the ground; and it is pulled towards the center of the field, tearing up the soil as it comes, the other meanwhile going out empty to meet it. When the latter reaches the middle of the field, the action of the engine is reversed, and it is dragged back to the engine, cultivating the land as it travels, while the other goes back to the headland empty. The pull out empty and working in is, of course, continued until the whole land has been tilled.

There are some other systems of steam-cultivation before the public, but in various respects they resemble those already enumerated. With Coleman's method there may be a slight saving of time at the ends, but there is, on the other hand, a trifling loss of power. In every sense of the term, the systems of the Messrs. Howard, and Fowler and Co., are the most popular. Each of these leading systems has its advocates and its advantages. It is certainly a much more expensive plan to have two engines, but yet for letting to hire it may be the best and cheapest, as they take the apparatus from one place to another, and set to work again more rapidly. It is, however, easy enough to keep one steam-engine always running at full speed, and there seems little reason to keep one engine simply to look at the other, seeing the expense is the draw-back which prevents their universal adoption. Besides, the single engine on the roundabout system is decidedly the best for working up of corners of fields, and as it does not move along headlands, it does not destroy them; but can continue working while the locomotive remains idle. On soil where there are many stones, it is better first to grub the land thoroughly, and remove the stones, before using the plough.

Where the fields are pretty large, stones not abundant, and the soil heavy, the odds are all in favor of steam cultivation. Not only is the tillage more thorough than could be otherwise accomplished, but there is a greater chance of getting the land worked in better condition. That is to say, the great speed by which the soil can be turned over—on an average, about three-fourths of an acre per hour—enables the advantages of weather and seasonable soil to be more extensively embraced. Then every farmer knows,

or should know, the benefits of deep cultivation, where the soil admits; and by steam-power, more than in any other way, this great desideratum is likely to be obtained.

There is a danger, however, arising from deep ploughing, provided the increased depth is not gradually affected. For instance, if three or four inches of fresh soil is suddenly brought to the surface, and the manuring applied in the usual way, the succeeding crop, if not even crops, is often disappointing. The fresh excavation, in short, has not been fertilized unless very special treatment is bestowed. The best time to introduce the deep furrow is preparatory to the green crop, as with the bulk of the ordinary farming (Scotch especially) that is the rotation which is accompanied by the heaviest manuring of the course. Stunted crops do not now follow the introduction of steam-power, or rather deepened cultivation, to any material extent, but when the causes and cures were not so well known in the earlier days of steam-ploughing history, failures for a year or two were more notable. The high price of horses, lately developed into extravagance, together with the growing and already high rate of farm-servants' wages, have stimulated considerably the application of steam-power to the tillage of the soil of Britain. The two principal firms at Leeds and Bedford, already referred to, have an enormous demand just now from all quarters for steam-cultivating apparatus. In Britain, it is computed there are considerably over 1000 steam-tackles at work, and the exports to the continent, to some parts of America, to the East and West Indies, and to Egypt, is considerable, and growing.

PLOUGHGATE OF LAND, in the Law of Scotland, is an expression denoting a quantity of land of the extent of 100 acres Scots. No person is qualified to kill game in Scotland who has not a ploughgate of land, and this is still the law. *Paterson's Game-laws of United Kingdom*, p. 158.

PLOVER (*Charadrius*), a genus of birds of the family *Charadriadae* (q. v.), having a straight compressed bill; the upper mandible alone slightly inflated and slightly bent at the point; the nasal groove extending about two-thirds of the length of the bill, the nostrils longitudinally cleft near the base; the legs not very long, naked a little above the tarsal joint; no hinder toe; the wings rather long and pointed, the first quill-feather the longest. The species are numerous, and are found in every quarter of the globe; many of them are birds of passage. They chiefly frequent low moist grounds, where they congregate in large flocks, and feed on worms, molluscs, insects, &c.; but some of them visit mountainous regions in the breeding-season. They fly with great strength and rapidity, and run with much swiftness. The flesh and eggs of many of them are esteemed delicacies. One of the British species is the Dotterel (q. v.). Another is the **GOLDEN or YELLOW PLOVER** (*C. pluvialis*), a rather larger bird, of a blackish color, speckled with yellow at the tips and edges of the feathers; the throat, breast, and belly black in summer, whitish in winter. The Golden P. is a bird of passage, visiting in summer the north-

1, Ringed Plover; 2, Gray Plover; 3, Golden Plover.

ern parts of Europe, of the west of Asia, and of North America; and migrating to the south in winter. It is known in almost all parts of Europe, and is common in many parts of Britain, breeding in the northern parts. Great numbers frequent the sandy pastures and shores of the Hebrides and of the Orkney and Shetland Islands. It makes an artless nest, little more than a slight depression of the ground, and lays four eggs. The parent birds show great anxiety for the protection of their young, and use various stratagems to divert the attention of an enemy.

The Golden P. exhibits great restlessness on the approach of wet and stormy weather, whence its specific name *pluvialis*.—The **RINGED P.** (*C. hiaticula*), a much smaller bird, not so large as a song thrush, is found at almost all seasons on the shores of the

British Islands, frequenting sandy and shingly flats, from which the sea retires at ebb-tide. It is often to be seen also on the banks of large rivers, and not unfrequently of lakes and ponds. It is found in most of the northern parts of Europe and Asia, and in Iceland and Greenland. It is grayish-brown above, whitish beneath, with a collar of white round the neck, and below it a black—in winter, a brown—collar; the head marked with black and white; a white bar on the wing. Very similar, but smaller, is the *KENTISH P.* (*C. Cantianus*); and also similar and of similar habits is the smallest of the British species, the *LITTLE RINGED P.* (*C. minor*). Both of these are rare in Britain.—North America has a number of species of *P.*, one of which, the *AMERICAN GOLDEN P.* (*C. Virginianus*), very closely resembles the Golden *P.* of Europe; and another, the *KILDEER P.* (*C. vociferus*), abundant on the great western prairies, and not unfrequent in the Atlantic states, utters, when approached by man, a querulous or plaintive cry, like the lap-wing.—The name *P.* is often extended to species of *Charadriidae* belonging to other genera, as *Squatarola*, in which the nasal grooves are short, the tip of the bill is tumid, and there is a rudimentary hind-toe. To this genus belongs the *GRAY P.* (*S. cinerea*) of Britain, a species rather larger than the Golden *P.*, and chiefly known as a winter visitant. Its geographic distribution extends over most of the northern parts of the world.

PLUM (*Prunus*), a genus of trees and shrubs of the natural order *Rosaceæ*, suborder *Amygdaleæ* (q. v.) or *Drupaceæ*; the species of which have the stone of the fruit sharp-pointed at each end, with a longitudinal furrow passing all round, and a smooth surface, the fruit covered with a fine bloom, and the young leaves rolled up. The Common *P.*, the Bullace, and the Sloe, are generally reckoned by botanists as distinct species, but with much doubt if they are really distinct, as the *P.* passes into the Bullace, and the Bullace into the Sloe by insensible gradations; although there is so wide a difference in general appearance, size of leaves, and size as well as quality of fruit, between the best cultivated plums and the sloe, that it is not without an effort we can imagine them to have sprung from a common stock. The COMMON *P.* (*P. domestica*) appears in a wild state in woods and hedges in many parts of England and on the continent of Europe; probably, however, often derived from the seeds of cultivated trees. It is commonly described as destitute of spines, and as further differing from the bullace in having the under-side of the leaves smooth except when they are very young; but if these characters are adopted, many of the cultivated plums must be referred to the bullace (*P. insititia*) as their original; nor does the ovate fruit afford a more certain character, some of the finest garden plums being globose or nearly so, like the bullace. The varieties called *Damson* (q. v.) are particularly like the bullace, except in the form of the fruit. Cultivated plums vary greatly in the size, form, color, and flavor of the fruit. The fruit of some varieties, as the *White Magnumbonum*, is two inches long; while damsons of the same shape are not quite one inch, and a single fruit of the one is equal to at least eight or ten of the other.

The best varieties of *P.* are among the most delicious dessert fruits; among these, the *Green Gage* (*Reine Claude* of the French) is one of the most esteemed both in Britain and on the continent of Europe, and is unsurpassed both in sweetness and in flavor. The inferior varieties are used in pies, conserves, and sweetmeats. Some of them are very austere. In moderate quantity, plums are wholesome enough; but excess in the use of them is very apt to produce colic, diarrhoea, and cholera. The danger is greater, if they are eaten before they are perfectly ripe. A very pleasant wine is made from plums; and in some parts of Europe a strong spirit is distilled from them after fermentation; but for this purpose they are mixed in the south of France, with honey and flour, and in Hungary with apples.—The dried fruit, variously known as *Dried Plums*, or *French Plums*, and *Prunes* (q. v.), is much used for the dessert; and the somewhat austere fruit of the *St. Julien Plum*, cultivated in the south of France, becomes, when dried, the medicinal prune, used as a mild laxative. The drying of plums is effected very slowly in ovens, by a heat which is gradually increased. The process requires great care. The prunes called *Brignoles* are the produce of a variety grown principally near the little town of Brignole in Provence. The *P.* has been in cultivation from ancient times, and the first fine varieties were probably introduced into Europe from the East. The finer varieties are propagated chiefly by budding on stocks of the coarser kinds, which are procured either from seed or as suckers from the roots of *P.*-trees. The coarser varieties are propagated by suckers, without budding. A free loamy soil is best for plums. They are grown as standard, espalier, or wall trees. As standards, some of the varieties attain a height of more than 20 feet, with a moderately spreading head. The fruit is mostly produced on spurs; but some of the finest fruit on the shoots of the former year.

Among the varieties of *P.* are some which ripen their fruit early, and others which ripen late in the season. The blossom of some of the finer kinds is often protected by gardeners, like that of

peaches and apricots.—The wood of the *P.*-tree is hard and fine-grained, and is used in cabinet-work, in turnery, and for making musical instruments.—The *CASHMERE P.* (*P. Bokharensis*), cultivated in Cashmere and Bokhara, is regarded as a distinct species.—The *CHERRY P.*, or *MYROBALAN P.* (*P. cerasifera* or *Myrobalanus*), is a bush very similar to the sloe, with pendulous globular red fruit. It is a native of North America, but is often cultivated for its fruit on the continent of Europe. In Britain, it seldom produces fruit.—*P. maritima* is a shrub, indigenous to sandy soils on the sea-coast of North America from New Jersey to Carolina. It has a dark purple agreeable fruit, about the size of a pigeon's egg.

The *COCOA P.* or *ICACO* of the West Indies is the fruit of *Chrysobalanus icaco*, a tree of the natural order *Rosaceæ*, suborder *Chrysobalanaceæ*. The fruit resembles a *P.*, has a sweet although slightly austere taste, and is eaten both raw and preserved.—The fruit of *Parinarium excelsum*, another of the *Chrysobalanaceæ*, is called *Gray Plum* at Sierra Leone.

PLUM, DATE. See **DATE PLUM.**

PLUMAGE OF BIRDS. See **BIRDS** and **FEATHERS.**

PLUMATE'LLA, a genus of zoophytes (*Polyzoa*), having the polypidom fixed, membranaceous, convolvula-like, and branched; the polypes issuing from the extremities of the branches, with a crescent-shaped disc surrounded by a single series of many ten-

Plumatella Repens.
(From Johnston's *British Zoophytes*.)

tacles. The species are found in fresh water, attached to stones, &c. *P. repens* is a common British species, sometimes spreading over a square foot, and having branches three inches long, which adhere to some surface throughout almost their whole length. The tentacles are beautifully feathered with cilia on two opposite sides.

PLUMBAGINEÆ, or **PLUMBAGINACEÆ**, a natural order of exogenous plants, herbaceous or half-shrubby; with leaves somewhat sheathing at the base, and often clustered; flowers in panicles or in heads; calyx tubular, persistent, plaited; corolla very thin, of one or five petals; stamens five; ovary superior, 1-celled, with a solitary ovule; styles generally five; fruit a Utricle (q. v.). There are about 160 known species, chiefly found on the sea-shores and in the salt marshes of temperate regions. Some are found also in elevated regions, in all zones. Many have flowers of great beauty, and are therefore favorites in gardens. Some are occasionally used in medicine as tonics and astringents; others, being exceedingly acrid, as vesicants, particularly species of *Plumbago*. Thrift, or Sea-pink (q. v.), is the most familiar British example of the order.

PLUMBA'GO. See **BLACK LEAD.**

PLUME-BIRD (*Epimachus*), a genus of birds of the family

Plume bird (*Epimachus albus*)

Upurida (see *HOPOE*), but exhibiting points of resemblance

both to honey-suckers and to birds of paradise. The bill is slender and arched. The plumage is magnificent and gorgeous, scarcely excelled even by that of birds of paradise. The plume-birds are natives of New Guinea and New Holland. They are variously adorned with enormously long tail-feathers, great shoulder-tufts of broad feathers, loose downy plumes, &c. One species, *E. albus*, has remarkable thread-like prolongations of the shaft of some of its plumes.

PLUMED MOTH, the popular name of a group of 'Nocturnal Lepidoptera,' known to entomologists as *Fissipennis* and *Pterophorites*; remarkable for having at least a pair of the wings, and often all the wings, longitudinally cleft into two or more—some-

Plumed Moth.

times six—divisions, which are beautifully fringed at the edges. The wings are similar to those of other moths in their nervures, but the membrane which usually connects the nervures is interrupted. The Plumed Moths are extremely beautiful, but often pass unobserved in consequence of their small size. Some of them have the power of folding up the wing like a fan. Although they are ranked among the *Nocturnal Lepidoptera*, some of them fly about during the brightest part of the day.

PLUMMET, a weight of lead hung on a string, and attached to a frame, for the purpose of showing the vertical line.

PLUMULA'RIA, a genus of zoophytes (*Anthozoa*); plant-like, rooted, simple, or branched; with feathery shoots and offsets; and having hydra-like polypes in small cells arranged on one side of the shoot or branch, usually in the axil of a horny spine. The species are numerous, inhabitants of the sea, some of them very

Plumularia falcata (natural size):

a, the ovarian vesicle and four of the polype-cells of *P. falcata*, magnified. (From Johnston's *British Zoophytes*.)

common on the British coasts, attached to stones, shells, seaweeds, &c. They are very beautiful objects, even as seen by the naked eye, and still more when examined by the microscope; combining great delicacy with the utmost elegance. The polypes in a single *P.* are often exceedingly numerous; those of *P. falcata*, a very common British species, often to be found at low-water mark, have been calculated as 80,000 or 100,000 in number.

PLU'MULE. See **SEED**.

PLU'RALISM, in Canon Law, means the possession by the same person of two or more ecclesiastical offices, whether of dignity or of emolument. Pluralism has been held unlawful from the earliest times, and is forbidden by many ancient councils, as Chalcedon, c. x. (451 A.D.), 2d Nicæa, c. xv. (787 A.D.). This prohibition, however, was not regarded as absolute and admitting no possible exception; the natural ground of the prohibition being the impossibility, in ordinary cases, of the same individual adequately discharging the duties of more than one office. It has been held, therefore, that in cases in which this impossibility does not really exist, the union of two or more offices in the hands of one person might, speaking absolutely, be permitted without in-

fringing the divine law. Canonists therefore distinguish 'compatible' and 'incompatible' benefices or dignities. Two benefices may be incompatible in three ways—(1) if each requires residence (*ratione residentiæ*); (2) if the duties of both fall to be discharged at one and the same time (*ratione servitii*); or (3), if the revenue of either fully suffices for the becoming maintenance of the incumbent (*ratione sustentationis*). In other cases, benefices or dignities are considered compatible, and with the due dispensation, may be held by the same person. The rules by which dispensations from the law of residence are to be regulated, as well as the penalties for its violation, whether on the part of the patron or on that of the recipient, have formed the subject of frequent legislation, as in the 3d and the 4th councils of the Lateran, in the decretals of Innocent III. and many other popes, and especially in those of the Council of Trent.

In general, it may be said that the canon law regards as incompatible (1) two benefices each having the cure of souls; (2) two 'dignities'; (3) a 'dignity' and a cure of souls; (4) a cure of souls and a simple benefice requiring a residence. In other cases than these, the pope is held to have the power of dispensing. There is no department of discipline, however, in which the tendency to relaxation has been greater or more persistent; and one of the gravest of the abuses of the church was the prevalence of pluralism of 'incompatible' benefices, even of bishoprics; and although a constant effort was made to prevent this abuse, the evasions of the law were not only frequent, but even screened from punishment. In later times, the evil has in great measure disappeared in the Roman Catholic Church.

The English law, before the Reformation, in the main coincided with the canon law; and the legislation of Henry VIII. preserved the same general spirit, only substituting the dispensing power of the crown 'for that of the pope.

By 13 and 14 Vict. c. 98, it is provided that no incumbent of a benefice shall take and hold together with it another benefice, unless the churches are within three miles of one another by the nearest road, and the annual value of one of them does not exceed £100. Nor can two benefices be held together if the population of one exceeds 8000, and that of the other exceeds 500. The word benefice in this sense includes any perpetual curacy, endowed public chapel, parochial chapel, or district chapel. But a dispensation or license can be obtained from the archbishop, so as to allow two benefices to be held together; and if the archbishop refuse his license, the party may appeal to the Privy Council.

A special provision is also contained whereby the head ruler of any college or hall in the universities of Oxford or Cambridge, or warden of Durham University, is prohibited from taking any cathedral preferment or any other benefice. If any spiritual person holding a benefice shall accept another benefice contrary to the statute, the first benefice shall *ipso facto* become void. At the same time, provision is made by statutes for uniting benefices where the aggregate population does not exceed 1500, and the aggregate yearly value does not exceed £500.—In Ireland, no faculty or dispensation could be granted to any spiritual person to hold two or more benefices.—In Scotland, it is contrary to an old Scotch statute for a minister of the Established Church to hold two or more charges; but the question has arisen almost exclusively with reference to clergymen appointed professors before or after an appointment to a country charge, in which case a resignation is necessary of one of the offices within a certain time after the appointment; but this disqualification does not apply to city charges.

PLUSH (Fr. *peluche*), a variety of woven cloth, having a long shaggy pile on the upper surface. Although woven like velvet, it differs from it in the greater length of the pile, and in its not being clipped or shorn to a uniform length. Formerly, it was made of a double warp, one thread being usually double worsted yarn, the other, intended to form the pile, of goat's hair, and the weft of worsted; occasionally, only worsted was used. Now, it is made very extensively of silk and cotton, the silk taking the place of the goat's hair to form the pile. This silk plush is the material now almost universally used for making gentlemen's hats, instead of beaver-hair, as formerly. It is also worked in colored silks, for many articles of ladies' attire. See **WEAVING**.

PLU'TARCH (*Ploutarchos*), the biographer and moralist, was born at Charoneia in Boeotia. We can only approximate to the year of his birth. He tells us himself that he was a student of philosophy at Delphi, under Ammonius, when Nero was making his progress through Greece in 66 A.D.; and we may safely infer, therefore, that in that year he was beyond the age of puberty. He lived for some years in Rome, and in other towns of Italy, where he seems to have been much occupied with public business, and with giving lessons in philosophy—a circumstance to which he attributes his having failed to learn the Latin language in Italy, and his having to postpone his studies in Roman literature till late in life. During the reign of Domitian, he was delivering lectures

on philosophy at Rome; but we have not sufficient evidence for the statement, that he was preceptor to Trajan, or that that emperor raised him to consular rank. The later years of his life he spent at Charoneia, where he discharged the duties of archon and priest of Apollo. He lived down to 106, the eighth year of the reign of Trajan; but how much longer is not known. He was married to an amiable wife of the name of Timoxena, by whom he had several sons, who reached manhood, and left descendants.

The work by which P. is best known is his *Parallel Lives* of forty-six Greeks and Romans. These are arranged in pairs, each pair forming one book (*viblion*), consisting of the life of a Greek and a Roman, and followed by a comparison between the two men. In a few cases, the comparison is omitted or lost. The heroes of these biographies are the following: 1. Theseus and Romulus; 2. Lycurgus and Numa; 3. Solon and Valerius Publicola; 4. Themistocles and Camillus; 5. Pericles and Q. Fabius Maximus; 6. Alcibiades and Coriolanus; 7. Timoleon and Æmilius Paulus; 8. Pelopidas and Marcellus; 9. Aristides and Cato the Elder; 10. Philopœmen and Flamininus; 11. Pyrrhus and Marius; 12. Lysander and Sulla; 13. Cimon and Lucullus; 14. Nicias and Crassus; 15. Eumenes and Sertorius; 16. Agesilaus and Pompeius; 17. Alexander and Cæsar; 18. Phocion and Cato the Younger; 19. Agis and Cleomenes, and Tiberius and Caius Gracchus; 20. Demosthenes and Cicero; 21. Demetrius Poliorcetes and M. Antonius; 22. Dion and M. Junius Brutus. In addition to these are placed in the editions after the 46th *Parallel Lives*, the biographies of Artaxerxes Mnemon, Aratus, Galba, and Otho.

P. has no equal in ancient, and few in modern times, as a writer of 'Lives.' His power lies in his felicitous grasp of the character as a whole, and his skill in keeping minor details in subordination. It is not till the reader has seen the portrait in its completeness that his attention is attracted to accessory points. 'There are biographers (says an admirable writer in the *Quarterly Review*) who deal with the hero, and biographers who deal with the man. But Plutarch is the representative of ideal biography, for he delineates both in one.' Yet with all their artistic harmony, his lives abound with anecdotes and *bon-mots* in such profusion, that they form one of our chief authorities for the table-talk of the Greeks and Romans. Their popularity in ancient, mediæval, and modern times, with readers of every rank and age, is something extraordinary, and they have in consequence exerted a very powerful and a very salutary influence on the art of biography, as subsequently practised. The other writings of P., more than 60 in number, are included under the general title of *Moralia*, or Ethical Works. Several of these are not purely ethical in their tenor; while many of them are probably not by him, or if they are, do him small credit. Even in the best of the *Moralia*, there is no philosophical system to be found; their merits are not speculative, but practical; and their value consists mainly in their good sense, in the justness of their views on the ordinary affairs of human life; and in the benevolence of tone diffused throughout them. The best text of the *Lives* is that of Immanuel Bekker; the best translation in English is that of Dryden and others, as re-edited by Clough. The best edition of the *Moralia* is by Wyttenbach (Oxford, 1795—1800); and of the entire works, the editions of Reiske (Leip. 1774—1782) and Hutten (Tübingen, 1791—1805).

PLU'TEUS, in Classical Architecture, a wall filling up the space between two columns. Also the space between two orders, placed over one another, as in the amphitheatres, &c.

PLU'TO (Gr. *Plouton*, from *Plouteo*, to be rich), originally only a surname of HADES, as the giver or possessor of riches, is, in the Mythology of Greece, the third son of Kronos and Rhea, and the brother of Zeus and Poseidon. On the tripartite division of the universe, he obtained the sovereignty of the under-world—the realm of darkness and ghostly shades, where he sits enthroned as a 'subterranean Zeus'—to use the expression of Homer, and rules the spirits of the dead. His dwelling-place, however, is not far from the surface of the earth. P. is inexorable in disposition, not to be moved either by prayers or flatteries. He is borne on a car, drawn by four black steeds, whom he guides with golden reins. His helmet makes him invisible, whence, according to some scholars, his name of *Hades* (from *a*, priv., and *idein*, to see); although others, with at least equal probability, derive *Hades* from *hado* or *chado*, to receive or embrace, and translate the word the 'all-receiver.' In Homer, *Hades* never means a place, but always a person. Moreover, it is to be noticed that the poet does not divide the realm of the shades into two separate regions. All the souls of the dead—good and bad alike—mingle together. Subsequently, however, when the ethical conception of future retribution became more widely developed, the kingdom of the dead was divided into Elysium (q. v.), the abode of the good, and Tartarus (q. v.), the place of the wicked. This change also exercised an important influence on the conception of Pluto. The ruler of the under-world not only acquired additional power and majesty, but the very idea of his character was essentially modified. He was now regarded as a beneficent deity, who held the

keys of the earth in his hand, and possessed its metallic treasures (whence his new name *Pluto* or *Plutus*), and who blessed the year with fruits, for out of the darkness underground come all the riches and swelling fulness of the soil. Hence, in later times, mortals prayed to him before proceeding to dig for the wealth hidden in the bowels of the earth.

P. married Persephone (Proserpina), the daughter of Demeter (Ceres), after carrying her off from the plains of Enna. He assisted his brothers—according to the mythological story—in their war against the Titans, and received from the Cyclops, as a reward for delivering them from Tartarus, the helmet that makes him invisible, which he lent to Hermes (Mercury) in the aforesaid war, to Perseus in his combat with the Gorgons, and which ultimately came to Meriones. The Erinyes and Charon obey his behests. He sits in judgment on every open and secret act, and is assisted by three subordinate judges, Æacus, Minos, and Rhadamanthus. The worship of P. was widely spread both among the Greeks and Romans. Temples were erected to his honor at Athens, Elis, and Olympia. Among trees and flowers, the cyprus, boxwood, narcissus, and maidenhair were sacred to him; bulls and goats were also sacrificed to him amid the shadows of night, and his priests had their brows garlanded with cypress wreaths. In works of art, he resembles his brothers Zeus and Poseidon; only his hair hangs down somewhat wildly and fiercely over his brow, and his appearance, though majestic, as becomes so mighty a god, has something gloomy and terrible about it. There can be little doubt that he, as well as Pan (q. v.), helped to trick out the conception of the devil prevalent during the middle ages and not yet extinct. If it was from Pan that the devil derived those physical characteristics alluded to in the famous *Address to the Devil* by the poet Burns:

O thou, whatever title suit thee,
Auld Hornie, Satan, Nick, or Clootie,

it is no less certain that it is to P. he owes his position as 'king of Hell,' 'his Blackness,' and many of the insignia of his infernal royalty.

PLUTO'NIC ROCKS, the name given by Lyell to the Granitic Rocks, from the supposition that they were formed at considerable depth in the earth, and were cooled and crystallized slowly under great pressure. They were so designated in contradistinction to the Volcanic Rocks, which, though they have risen up from below, have cooled from a melted state more rapidly upon or near the surface. See GRANITE.

PLY'MOUTH, an English seaport and market town, and a parliamentary and municipal borough in the south-west of Devonshire, 246 miles west-south-west of London. It stands in the bight of Plymouth Sound (q. v.) between the estuaries of the Plym and Tamar. To the west of it is Stonehouse (q. v.), a township and coast-guard station, and still further west is Devonport (q. v.), the great naval and military station. The two former places, however, having become united by continuous lines of houses, have lost their individuality, and are (with Devonport, which is walled, fortified, and surrounded by a moat) now generally considered as one great town. Of this great center of fashion, trade, and naval and military preparation, P. proper, which covers an area of one square mile, may be called the city, and Devonport the west-end; while Stonehouse is an intermediate district, containing chiefly factories, barracks, victualling yards, hospitals, and other institutions. P. proper extends from Mill Bay on the west to the mouth of the Plym on the east. Its site is somewhat rugged and uneven; an eminence forming the suburbs runs along its north side, and another eminence, partly occupied by the citadel, fronts the Sound.

The chief buildings are the Royal Hotel, comprising an immense inn, assembly-rooms, a theater, and the Athenæum, all partially destroyed by fire in 1862, and rebuilt in 1863; public library, containing in its Cottonian collection 800 sketches by the old Italian masters; Guildhall, opened in 1874; St. Andrew's Church, the tower of which dates from 1490 (restored in 1874—1875); and Charles Church (1646—1658), dedicated to 'St. Charles the Martyr.' There are also several important educational establishments, some of which are endowed, as well as many charitable institutions. Mill Bay and Sutton Pool are two small inlets of the Sound, in which lie all the merchant-vessels bound for P. proper. Between these inlets, and running along the shore, is the eminence or high plateau of land, called the Hoe. From this ridge, whence the approach of the Spanish Armada is said to have been first descried, magnificent shore and sea views may be obtained. Its eastern end is occupied by the citadel, a fortress mounting 150 guns, which commands the entrance of the Cutwater (the lower estuary of the Plym), and of Sutton Pool. Mill Bay, on the west, is so deep that vessels of 3000 tons can lie at the pier at low-water. Here are the important Great Western Docks, covering an area of fourteen acres, and having a depth of 22 feet, constructed about the years 1855—1858. Close to these docks, and connected with them by a tram-line, are the railway termini.

In 1880, 8665 vessels, of 726,937 tons, entered, and 2943, of 639,455 tons, cleared the port. Commerce is carried on to a considerable extent with the Cape of Good Hope, the West Indies, and the Mediterranean; the coasting trade is also important, and the fisheries are productive. Pop. (1871) 70,091; (1881) 77,401.

P. described by Leland as being, in the reign of Henry II., 'a mere thing, an inhabitation of fishers,' was called by the Saxons Tameorworth (town on the Tamar); after the Conquest it was called Sutton (South Town); and it was not till the reign of Henry VI. that it received the name of Plymouth (mouth of the Plym). During the 14th and 15th centuries it was frequently attacked and set on fire by the French, and in 1512 an act was passed for the strengthening of its defences, which since then have greatly increased, until now the whole shores of the Sound are well defended by cannon, and a cordon of inland forts has been of late years constructed at immense cost, surrounding the Three Towns at a distance of from two to three miles.

PLYMOUTH, a town in Massachusetts, U. S., on Plymouth Bay, 37 m. S. E. of Boston, famous as the landing-place of the 'Pilgrim Fathers' from the *Mayflower*, December 11, 1620, o. s. Plymouth Rock is a granite boulder at the water's edge on which they landed. It is covered by a handsome granite canopy, and there is also a national monument to the pilgrims, completed in 1875. In Pilgrim Hall are preserved many relics of the first settlement of the country, among which are Governor Carver's chair and the sword of Miles Standish. The town has a good harbor and flourishing trade. Pop. (1870) 6338.

PLYMOUTH BRETHERN, a religious sect which sprang into existence about 1830—1835 in Plymouth, Dublin, and other places in the British islands, and which has extended itself considerably throughout the British dominions and in some parts of the continent of Europe, particularly among the Protestants of France, Switzerland, and Italy, and also in the United States of America. It seems to have originated in a reaction against exclusive High Church principles, as maintained in the Church of England, with everything of a kindred nature in other churches, and against a dead formalism associated with 'unevangelical' doctrine.

Many of the first members of the new religious communities formed in Plymouth and elsewhere were retired Anglo-Indian officers, men of unquestionable zeal and piety; and these communities began to appear almost simultaneously in a number of places. Their origin is, however, very much to be ascribed to the labors and influence of Mr. Darby, from whom the P. B. on the continent of Europe are very generally known as *Darbyites*. Mr. Darby was a barrister, moving in the highest circles of society; and under deeply religious impressions, became a clergyman of the Church of England, and lived for some time in a mud-hovel in the county Wicklow, devoting himself to his work; but afterwards left the Church of England from conscientious scruples, and became an evangelist unconnected with any church. In this character, he labored both in England and on the continent of Europe, preaching in French, English, and German. He also gave utterance to his opinions in numerous pamphlets, and in a quarterly periodical called *The Christian Witness*, which for a number of years was the 'organ' of the Plymouth Brethren. He continued for many years to visit the communities or meetings of Plymouth Brethren. His tenets, and those of the P. B. in general, are strictly Calvinistic: original sin and predestination, the efficacy of Christ's sacrifice, the merit of his obedience, the power of his intercession, the gracious operations of the Holy Spirit in regeneration and sanctification, are prominent points. Millenarian views are also generally entertained by the P. B.; and they usually practise the baptism of adults without regard to previous infant baptism. They acknowledge the sacrament of the Lord's Supper, and administer it to one another in their meetings, usually on every Sunday, or 'first day of the week,' in this, as in everything else, refusing to acknowledge any special ministers. They utterly reject confirmation.

Their most distinctive peculiarity, when contrasted with other Calvinistic churches, is their complete rejection of ecclesiastical organization. They suppose the whole Christian body in the world to have declined from truth and duty, like Israel of old, and therefore to have been 'corporately rejected of God,' and believe the true church to consist of themselves and of other chosen ones in the various Christian churches. They refuse to recognize any form of church government, or any office of the ministry; they insist much on the equal right of every male member of the church to 'prophecy' or preach; and in their meetings, after each hymn or prayer, there is usually a pause, that any one, moved by the Spirit, may undertake this office. They exclude persons known to have been guilty of gross sins from participation with them in the Lord's Supper, until proof is afforded of repentance. The P. B. reject every distinctive appellation but that of Christians; although a special denomination is found necessary to designate them; and, in fact, no one not holding their views could remain associated with them. A great schism took place

among them in consequence of doctrines preached at Plymouth and Bristol concerning the human nature of Christ; Mr. Darby vigorously opposing what he deemed a dangerous error, and he and his adherents utterly separating from the fellowship of those who maintained or even refused to condemn it. One of the most noted (if not notable) converts to the principles of the sect was the revivalist Guinness, who was baptized in 1860 by another Plymouth brother, Lord Congleton.

On the continent of Europe, the P. B. have in many places given great trouble to the Protestant churches, by their opposition to all ecclesiastical order or organization. See works by Mrs. Grattan Guinness (1861) and Dennett; and hostile criticisms by Carson (1870), Reid (1874), and Crookery (1879).

PLYMOUTH SOUND, a well-known roadstead on the south-west of Devonshire, important as a naval station, has considerable claims to the distinction of being called, as it frequently has been, the most beautiful estuary on the English coast. Its position at the entrance of the English Channel is much in its favor. It is two and a half miles wide, and extends inland for three miles. It penetrates into the country by means of the harbors of Hamoaze and Catwater, the estuaries of the Tamar and Plym respectively. On its west side is Cawsand Bay. The shores, which present many beautiful views, rise in hills of from 100 to 400 feet, and are dotted over with woods and with villages, and bound by coasts which are generally rocky and abrupt. Mount Edgecombe Park, the beautiful seat of the Earl of Mount Edgecombe, occupies the west shore of the sound. At the mouth of the Tamar is the small island of St. Nicholas, or Drake's Island, a pyramidal rock strongly fortified. The Sound is open to the south-west, from which direction strong winds frequently blow, and violent surges are thrown in from the Atlantic. In order to protect the shipping in the harbor, a massive stone breakwater, 1700 yards in length was constructed at a cost of about £1,500,000, and completed in 1841. See BREAKWATER. On a sunken rock just inside the breakwater and at its center, a strong stone fort has been within recent years erected; and an extensive series of stone batteries has been erected at Bovisand and Picklecombe on the mainland, on either side of the entrance to the harbor. Fourteen miles south-west of Plymouth is Eddystone Light-house. See EDDYSTONE.

PNEUMA'TIC DISPATCH. This name is given to a mode of sending parcels, mail-bags, or telegram papers through a tube by atmospheric pressure, or by a partial vacuum. Early in the present century, Mr. Medhurst conceived the idea of some such contrivance. He proposed to construct air-tight tunnels, with carriages moving through them on rails; and these carriages were to be propelled by compressed air from behind, or else by suction in virtue of a vacuum formed in front of them. Medhurst was laughed at by his contemporaries as a visionary; but his speculations were called to mind in later years, and led to the attempts noticed under ATMOSPHERIC RAILWAY.

In 1861, was announced a *Pneumatic Dispatch* project, based on a reconsideration of the causes of failure in the earlier schemes. The conveyance of passengers and of bulky goods was not here contemplated; parcels and mail-bags were the articles held chiefly in view. To test the theory, a quarter of a mile of iron tube was experimentally laid down near Battersea, with a fair average of gradients and curves purposely given to it. The tube was about 30 inches in diameter; and it was found easy to propel a train through the tube consisting of two iron carriages of 7 cwt. each, at the rate of 30 miles an hour.

After many financial discouragements, a *Pneumatic Dispatch Company* obtained capital in 1862, and began operations in 1863. The experimental tube was removed to London, and laid down beneath the roadway of Seymour Street, Euston Square, from the Euston station of the London and North-western Railway to the N.W. District post-office in Eversholt Street—a distance of one-third of a mile. Mail-bags being successfully transmitted in this way, the company commenced in 1864 the construction of a tube on a larger scale, and this has since been completed. The tube is laid down from Euston Square to St. Martin's-le-Grand, by way of Tottenham Court Road, Holborn, and Newgate Street—a distance of 2½ miles. The tube is of large size, nearly 4½ feet in diameter, laid down at as small a depth beneath the carriage-way of the several streets as the water and gas pipes will permit. It is chiefly of cast-iron; but some portions on a sharp curve are of brick. There is a large engine-house on the south side of Holborn, near Lincoln's Inn Fields, to supply all the power for working the whole tube in both directions. Rarefied air in one-half of the tube draws a train of iron carriages, laden with parcels and mail-bags, from Euston Station to Holborn; and compressed air drives them through the other length of tube from Holborn to the General Post-office—there being suction in the one case, and pressure in the other. A reverse action brings trains in the other direction. The necessary amount of rarefaction in the one case, and of compression in the other, was determined by experiment;

but both are produced by means of a revolving fan of peculiar construction and large dimensions worked by a powerful steam-engine at the Holborn station. If this mode of transmission were to come into general use, there would be great saving of time in the delivery of letters and parcels, and a material lessening of the number of parcels and mail-vans and carts in the overcrowded streets of the metropolis.

It is to be regretted that a work so successful in a scientific and engineering point of view should still remain undeveloped in a commercial sense. The Postmaster-general, the railway companies, and the great carriers, have made no practical working engagements with the Pneumatic Dispatch Company; and this costly tube, with the engine-house in Holborn, has now remained silent and unused for several years. This of course has checked any extension of the system into other districts. We cannot resist the conviction that a better result will present itself sooner or later.

The problem of *passenger* conveyance within a pneumatic tube was shown to be practicable by Mr. Rammell, in an experiment tried at the Crystal Palace in 1864; but nothing further has been done in the matter.

More success has attended the introduction of a system for transmitting small rolls of paper through tubes of a few inches diameter, by pneumatic pressure. Mr. Siemens introduced it at Berlin; it was next tried with success at Paris; Mr. Latimer Clark constructed similar apparatus in London; and the plan is now in regular use in the telegraph department of the new buildings connected with the General Post-office in St. Martin's-le-Grand, while it is also used in some of the chief provincial cities and towns. In 1875 the number of tubes in London was 24, with an aggregate length of nearly 18 miles; there were 4 tubes in Liverpool, 3 in Dublin, 5 in Manchester, 3 in Birmingham, and 1 in Glasgow. Small tubes, two to three inches in diameter, are arranged for the reception of telegram forms or papers, made up into a roll, and put into a felt cylinder. The purpose is to economize time and expense in conducting the government postal telegraph business by *blowing* along the telegram forms at a rate of 30 miles an hour, instead of sending them by street conveyance.

Two parallel tubes have been laid down beneath the pavements of the streets from the General Post-office to various parts of London, and also in some of our large provincial cities and towns; additions being made to the length of the tube according as the system becomes practically developed. One tube in each pair may be called the down line, the other the up; the two are placed in connection at each end; and one steam-engine works them both. The felt cylinder very nearly fills up the tube, but still moves easily along; this movement is brought about either by the formation of a partial vacuum in front of the cylinder, or by compressing the air behind it; and the steam-power is so applied as to produce either or both of these two results, according as convenience may suggest. An ingenious plan is adopted for accommodating one or more intermediate offices, just as local stations are accommodated between the two termini of a railway. The cylinder or *carrier* travels from end to end of the tube, unless a block or check action is purposely put in force at an intermediate station; and the mode of effecting this is one of the most beautiful of Mr. Siemens's inventions relating to the subject. Two pieces of pipe, the *receiver* and the *transmitter*, are made exactly alike, and are so pivoted together that either may be adjusted into a cavity cut in the tube, and made temporarily to form part of it. The carrier, we will suppose, is intended to stop at the intermediate stations, to admit of the removal of some telegram papers and the introduction of others. A click is heard; the carrier strikes against an obstruction in the receiver; the cavity is opened; the exchange of papers is made; the carrier is re-introduced, but into the transmitter instead of the receiver; the cavity is closed again; and the carrier resumes its journey. All this is the work of a few seconds merely. If the intermediate station has nothing to send and nothing to receive, the transmitter alone is used, and the carrier travels on without stopping.

The up-tube and the down-tube have each its apparatus of receiver and transmitter. The felt cylinder and its contents being very light, a slight rarefaction of the air in front of it, or condensation of the air behind it, is sufficient to produce a speed equal to twenty or thirty miles an hour. Practically, there is a *current* of air maintained, circulating through the two tubes and their terminal connections; wherever a carrier is placed in this current, it is blown along; and there may be two or more carriers traveling at the same time.

PNEUMATIC TROUGH, is a piece of chemical apparatus originally devised by Priestley, and now in daily requisition in every laboratory. By its means, gases can be collected in vessels for experiments or examination, and can be decanted from one jar to another with as much ease as if we were dealing with liquids. The pneumatic trough consists of a vessel of water, provided with a ledge or shelf at the depth of two or three inches

from the top. The jars in which the gas is to be collected are filled with water, and placed with their mouths downward upon the shelf, which is kept a little under water, so as to prevent the entrance of air into the jars. When the edge of the jar is brought over the extremity of the tube carrying the gas, the bubbles of gas rise through the water, collect in the upper part of the jar, and displace the liquid. As soon as a jar is filled, it may be removed by sliding under its open mouth, while still under water, a plate or tray containing enough of water to cover the edge of the jar; and oxygen and many other gases may be thus preserved for hours. Another jar full of water is substituted for the removed jar. The trough is best constructed of japanned copper, and may be made of any size corresponding to that of the jars; and in the shelf a groove should be made about half an inch in width, and the same in depth, to admit the extremity of the gas-delivering tube beneath the jar.

PNEUMATICS (Gr. *pneuma*, spirit or breath, air) is the science which treats of the mechanical properties of æriform fluids, such as their weight, pressure, elasticity, motion, &c. The great representative of the æriform fluids is the atmosphere. The atmosphere is very frequently called 'air,' to distinguish it from the others, which are known as 'gases.' The fact of air having weight, and generally exercising pressure and resistance, was unsuspected by most of the ancients, though they were aware of the latter property in particular cases, from seeing and feeling the effects of the wind; but the idea that air in a state of rest exerts pressure on a body immersed in it, never seems to have occurred to them. Aristotle, however, asserted that air had weight, and so did several subsequent philosophers; but the truth of this opinion was not established till the time of Torricelli (q. v.), who not only showed that it had weight and exerted pressure, but also found the amount of this weight or pressure. See **ATMOSPHERE**. Pascal (q. v.) completed the investigation, and invented the Barometer (q. v.). The experiments of these philosophers proved that what is called 'suction' is nothing more than an effect of the pressure of the air on one side of a body, unbalanced by an equal pressure of air on the opposite side of it. To this property of air we owe the working of the various kinds of Pumps (q. v.), the Barometer (q. v.), the siphon, cupping-glass, &c. But the great distinguishing feature of æriform bodies is the repulsive force which their molecules exercise over each other, and the consequent expansion of these bodies when pressure is removed, or compression when pressure is increased. The investigation of the expansibility and compressibility of air was carried on by means of the Air-pump (q. v.), an invention of Guericke (q. v.), and soon resulted in the discovery of a law by Boyle (about 1650), and Mariotte (1676), called *Mariotte's Law* (q. v.), which affirms that 'at a given temperature the volume of a gas is inversely as the pressure.' See **GASES**.

The second great law of tension and pressure is that of Dalton and Gay-Lussac (1801), which states that 'when the tension remains the same, the density of a gas varies inversely as the temperature'—that is to say, when the temperature is increased by equal increments, the bulk is increased by equal increments. The motion of gases is subject to the same laws with that of liquids, the laws which regulate the motion of liquids depending for their efficacy not on their liquidity, but on the fluidity (see **FLUID**) of these bodies. The flow of gases in tubes seems to be retarded by friction against the sides, in the same way as that of water is, and the diminished efflux at an orifice shows that the *vena contracta* exists for gases as well as for liquids. Abundance of examples and further explanations of the properties of air will be found under such heads as **ATMOSPHERE**, **BALLOON**, **BAROMETER**, **DIVING-BELL**, **MAGDEBURG HEMISPHERES**, &c.

PNEUMOGASTRIC NERVE, or *Par Vagus*, derives the first of its names from its supplying the lungs and stomach with nervous filaments, and the second from the wandering course which it pursues. It emerges from the medulla oblongata by eight or ten filaments, which unite and form a flat cord, that escapes from the cavity of the cranium (in association with the glossopharyngeal and spinal accessory nerve) by the jugular foramen. In this foramen, it forms a well-marked ganglionic swelling, while another is observed immediately after its exit from the skull. The nerve runs straight down the neck between and in the same sheath as the internal jugular vein and the carotid artery. Below the root of the neck, its course is different on the two sides; the right nerve running along the back of the œsophagus, is distributed to the posterior surface of the stomach, and finally merges into the solar plexus; while the left nerve runs along the front of the œsophagus to the stomach, sending branches chiefly over its anterior surface.

From anatomical considerations, based on the distribution of this nerve, and from the results of experiments on animals, it may be concluded that this is a mixed nerve, containing filaments both of sensation and motion. The pulmonary branches exercise a most important influence upon the respiratory acts, for

when the pneumogastrics on both sides have been divided above the giving off of the pulmonary branches, the most severe dyspnoea comes on, the number of respirations is much diminished, and the animal breathes as if it were asthmatic; after a short time, the lungs become congested and dropsical, and the bronchial tubes filled with a frothy serous fluid; and if the cut ends of the nerves are kept apart, the animal never survives above three days. The gastric branches influence the movements of the stomach, while their destruction does not materially affect the secretion of the gastric juice or the process of chylification. Loss of voice and difficulty of breathing have been frequently traced to the pressure of an aneurism or other tumor on the recurrent or inferior laryngeal. Hooping-cough is ascribed by many high authorities to an affection of the pneumogastric nerve; and the violent spasmodic cough which accompanies enlarged bronchial glands, is probably due to the irritation of its pulmonary branches. The sympathy which exists between the digestive and the respiratory and circulating organs, is explained by the anatomical relations of this nerve. For example, both asthma and palpitation of the heart are often to be traced to some deranged state of digestion. Vomiting may be excited by irritation of the central or the distal extremities of the nerve. In disease of the brain, the vomiting, which is often an early symptom, is caused by irritation of the central extremity; and in sea-sickness, it is that extremity also which is irritated by the disturbed state of the circulation in the cranium; while by introducing emetic substances into the stomach, the vomiting is produced by the irritation of the peripheral (or distal) filaments.

PNEUMO'NIA, or Inflammation of the Substance of the Lungs, is a disease which is divided by pathologists into three distinct stages, corresponding to different degrees or periods of inflammatory action. The first stage is that of *engorgement*, in which the lung or a portion of it is gorged with blood, is of a darker color externally, and crepitates (or crackles) less under pressure than healthy lung does; the air that ought to exist in the pulmonary cells being in a great measure replaced by fluid. On cutting the engorged portion, the section is seen to be redder than natural, and to yield a great quantity of reddish and frothy serum. The most engorged portions will generally float in water, although they are heavier than healthy lung. If the inflammation continues, new characters appear. The affected portion of the lung ceases to crepitate under pressure, and sinks when placed in water, in consequence of its now containing no air. The spongy character of the lung is gone. It is now solid, and the cut surface so closely resembles that of liver, that the term *hepatisation*, first suggested by Laennec, is generally applied to this stage. On examining with the microscope a torn fragment of the hepatized lung, it will be seen to be composed of small red granulations pressing upon one another, which are doubtless the air-cells clogged up, thickened, and made red by the inflammation. In the third and most advanced stage, the pulmonary tissue remains, as in the last stage, dense, solid, and impervious to air; but its section, in place of being red, is now of a reddish-yellow, or straw, or drab, or stone color, or is of a grayish tint; and the little granulations which were red in the second stage, are now whitish or gray, from the presence of pus or matter, which permeates through the pulmonary tissue, rendering it very soft and friable. To this stage, which is in reality one of *diffused suppuration*, Laennec applied the terms *gray hepatisation*, or *purulent infiltration*.

Besides revealing to us the above information regarding the changes which the pulmonary textures undergo in the three stages of this disease, morbid anatomy teaches us that inflammation does not attack all parts of the lung on both sides indiscriminately. It is much more common on the right side of the body than the left. Of 210 cases collected by Andral, 121 were on the right lung alone, and 53 on the left side alone; while in 25 it was double (i. e., occurred in both lungs), and in six the seat was uncertain; so that pneumonia is more than twice as common on the right side as on the left, and only occurs on both sides together as often as once in eight times. According to Grisolles, however, whose *Traité Pratique de la Pneumonie* is the standard work on this disease, the relative frequency with which the right lung is affected is rather less than two to one (11 : 6). Moreover, pneumonia is considerably more common in the lower than in the upper lobes of the lung—a point of great importance in diagnosis. Of 88 cases observed by Andral, the inflammation was found to affect the lower lobe 47 times; the upper lobe, 30; and the whole lung at once, 11. Inflammation of the bronchial tubes so constantly accompanies inflammation of the tissues of the lung, that although bronchitis often exists without pneumonia, pneumonia never occurs without bronchitis. Moreover, a certain amount of pleurisy or inflammation of the investing membrane, accompanies pneumonia in a very large majority of cases.

The alterations which take place in the tissue of the lung give rise to important modifications of the ordinary sounds yielded by

auscultation and percussion; the discrimination of which, however, belong to the physician.

The following are the general symptoms, as distinguished from the physical signs, of pneumonia. The disease generally commences with inflammatory fever; and pain in the side, due to pleurisy in most cases, soon supervenes. The breathing is always more or less affected, especially when the upper lobe is inflamed. According to Professor Gairdner, the dyspnoea of *pure pneumonia* is a mere *acceleration* of the respiration, without any of the heaving or straining respiration observed in bronchitis, or in cases where the two diseases are combined. Delirium is a very frequent, and always a dangerous symptom, indicating that the due arterialization of the blood is much interfered with, and that the impure circulating fluid is affecting the brain. The cough is usually dry at first, but in a few hours it is accompanied by the expectoration of sputa of so characteristic a nature as to afford almost certain evidence of the presence of the disease. On the second or third day, the expectoration, which previously consisted merely of a little bronchial mucus, consists of transparent and tawny, or rust-colored sputa, which unite in the vessel containing them into one gelatinous mass. The color is owing to the complete blending of the blood and mucus, and in proportion to the quantity of the former, the sputa is more or less deeply tinged. So long as the expectorated matter flows readily along the side of the vessel when it is tilted, there is reason to believe, unless physical signs tell us otherwise, that the inflammation is still in the first stage; but when the sputa are so viscid that the vessel may be inverted and strongly shaken without their being detached, there is reason to fear that the pneumonia has reached the second stage.

If improvement now commences, the sputa become less tenacious, less rust-colored, and gradually like the expectoration of common catarrh. But if the disease advances, the rust-colored sputa, although in less quantity, may go on to the end; or there may be no expectoration, either on account of its own tenacity, or of the patient's want of power to eject it, in which case the air-passages get gradually filled, and death from suffocation occurs; or there may be the expectoration of a fluid of the consistence of gum-water, and of a brownish-red color (resembling prune-juice), which, according to Andral, affords strong evidence that the disease is in its third stage; or, lastly, pure pus may be excreted during the third stage.

In its first and second stages, this disease is tolerably amenable to treatment. Whether, when the lung has reached the third stage, it is still susceptible of repair, we cannot tell, because we have no certain sign of the commencement or establishment of the third stage during life, although we may guess that it is established, if the face has become very pale and corpse-like; if there is the prune-juice or purulent expectoration; and if the disease has lasted for a sufficient time to have advanced so far, although it would be very difficult to state, with any approach to accuracy, what the necessary time is. The average duration of pneumonia may be placed at ten days or a fortnight.

Of the causes of this disease, very little need be said. Sometimes no cause can be traced. Very often it is the consequence of exposure to cold, especially when the body was previously heated by exercise; but why such exposure should in one person cause pneumonia, in a second, pleurisy, in a third, pericarditis, and in a fourth, peritonitis, we cannot tell.

The following is a brief outline of the treatment to be adopted, provided the patient was previously strong and healthy. In the first stage, free venesection, tartarized antimony (one-third of a grain to half a wine-glassful of water every hour, and the dose to be increased to a grain or more hourly, if there is no purging or vomiting, which may often be prevented by the addition of a few drops of laudanum to each dose), and antiphlogistic regimen, generally are of service. Under this system there are often signs of improvement in five or six hours, although sometimes there is no change for the better till twenty-four hours or more have elapsed. When the disease has reached the second stage, in preference to continuing the antimony, we should as speedily as possible get the system gently under the influence of mercury, in the mode recommended in the articles PERICARDITIS and PERITONITIS. If there is great depression of the vital powers, as indicated by a feeble and irregular pulse, and the other ordinary signs of sinking, it will be requisite to administer stimulants, such as wine and carbonate of ammonia, and to feed the patient on beef-tea.

There are few diseases in which it is of greater importance to watch the patient during convalescence than in pneumonia. The convalescence is often rather apparent than real, and as Dr. Watson truly observes: 'A patient can never be pronounced perfectly secure so long as any trace of crepitation remains in the affected lung, and this may often continue long; nay, it not unfrequently ceases only on the supervention of another more surely fatal though less rapid disorder—viz., tubercular consumption.'

PO (anc. *Eridanus* and *Padus*), the largest river of Italy, rises in two springs on the north and south sides of Monte Viso,

one of the Cottian Alps, close to the French frontier, and in lat. about 44° 40' N. It flows eastward for upwards of 20 miles, when, arriving before Saluzzo, it emerges from its rocky defiles, and enters upon the plain. From Saluzzo, it flows north-north-east past Turin; and arriving at the town of Chivasso, it changes its course toward the east, in which direction it flows to its embouchure in the Adriatic. Upwards of 50 miles above its mouth, it begins to form its delta, the principal branches being the *Po della Maestra*, on the north, and the *Po di Primaro*, on the south. The unhealthy marsh of the *Valli de Commacchio* extends immediately north of the Primaro branch. The Po receives from the left, the Dora Riparia, Dora Baltea, Sesia, Ticino, Adda, Oglio, and Mincio; from the right, the Tanaro, Bormida, Trebbia, Taro, Parma, Enza, Secchia, and Panaro. At Turin, the Po is about 750 feet broad; at Pavia, 1050 feet; at Cremona, 2650 feet; and below Polesella, after throwing off the Po di Primaro branch to the south, its breadth is about 850 feet. It has an entire length of 400 miles, is navigable for small barges 60 miles from its source and drains an area of nearly 40,000 square miles.

POA. See MEADOW GRASS.

POACHING, though not strictly a legal term, has so long been appropriated in popular speech to describe a well-known offence, that it is now usually adopted in legal works. It means trespassing on another's lands for the purpose of catching or pursuing game; and it is likewise extended to the cognate offence of unlawfully catching or pursuing fish in another's waters.

1. *As to poaching game.*—The general law as to who is entitled to game, and in what circumstances, is stated under the head **GAME**. As a general rule, the proprietor of land is the only person entitled to catch and kill the game upon the land; and where the land is let, then, in England and Ireland, if there is no express agreement to the contrary, the tenant is exclusively entitled to the game. In Scotland, the landlord is so entitled; but generally there is an express stipulation upon the subject. As regards hares and rabbits, however, the law was altered for the whole United Kingdom by the Ground Game Act, 1880, which gives to every occupier of land an inalienable right, jointly with the proprietor, to kill such ground game, under certain restrictions as to the methods of killing and the number of persons entitled to kill. This change was thought necessary from the damage done to crops by hares and rabbits, in many cases directly due to excessive preserving. The person entitled to kill the game on the land, can alone give permission to a stranger to enter and kill game there; and if this permission is not obtained, such stranger, whether qualified or not—i. e., whether he pays the government tax or not—is a poacher, if he go and kill the game. The right of the occupier under the Act of 1880 cannot be transferred, and does not imply the power of giving leave to others to kill ground game. In England, there is a Day-poaching Act and a Night-poaching Act, imposing penalties on poachers. By the Day-poaching Act (1 and 2 Will. IV. c. 32, s. 30), whoever unlawfully goes upon lands not his own to pursue or kill not only Game (q. v.), but also rabbits, woodcocks, snipes, quails, and landrails, is liable to a penalty of £2.

Any person whatever, whether interested in the lands or not, may institute the proceedings for the punishment of the poacher; and the informer is entitled to half the penalty, the other half going to the poor of the parish. When a poacher is found trespassing on lands in search of game, the person entitled to the game there, or the tenant, or a game-keeper, or servant of either, may demand the poacher's name and place of abode, and if it is refused, may arrest such poacher, and take him before a justice of the peace; but the poacher must be taken within twelve hours before the justice, otherwise he is entitled to go at large. In such a case a penalty of £5 may be inflicted. If game be found on the poachers at the time they are caught, and it appear to have been newly caught, the party who is entitled to arrest him is entitled to seize the game also. If the poacher when convicted do not pay the penalty within the time fixed by the justices, he may be committed to the house of correction for a period not exceeding two calendar months. The party may appeal against his conviction to the Court of Quarter Sessions; but he must either remain in custody in the interval, or give security for the costs. The offence of poaching is punished more severely when five or more go out together, and in such case each is liable to a penalty of £5. Moreover, if any of these five or more persons, acting in concert, be armed with a gun, and use violence, each is liable to an additional penalty of £5. As to the Night-poaching Act (9 Geo. IV. c. 69), it is provided that any person by night—i. e., between the first hour after sunset and the first hour before sunrise—unlawfully trespassing in search of game, shall for a first offence be committed by the justices to the house of correction for three months; for a second offence, shall be committed for six months, the convicted person being in each case liable to a further term of imprisonment on failure to give securities at the end of his sentence; and for a third offence, shall be guilty of a misde-

meanor, and be imprisoned for two years. In case such night poachers are found on the lands and in the act, the owner or occupier of the land or his servants may arrest the poachers, and take them before justices.

If the night-poacher, when arrested, use firearms, sticks, or offensive weapons, he shall be guilty of a misdemeanor, and be punishable by two years' imprisonment in addition. In case of three or more night-poachers being armed with guns, bludgeons, or other offensive weapons, each is guilty of a misdemeanor, and is liable to imprisonment for three years. The provisions of the Night-poaching Act were, by the Act 7 and 8 Vict. c. 29, generally extended to public roads and highways, it having been found that in such places the original act was evaded, and the risk of murder greatly increased. Under the former law, it was, as already mentioned, incompetent for any person except the owner or occupier of the lands to apprehend the poacher, and even this could be done only when the poacher was caught in the act on the lands; and hence, even constables had no power to seize the poacher, though seen to be coming from such lands. But by the Poaching Prevention Act (25 and 26 Vict. c. 114), which applies to the United Kingdom, if a constable now meet a suspected poacher in any public place, whom he has reason to suspect of coming from land where he has been poaching, and of having in his possession game unlawfully got, or a gun or net, such constable may stop and search the poacher; and if game, or implements for taking game, are found on him, may seize and detain them, and summon him before the justices. When before the justices, if it be proved by circumstantial evidence or otherwise that such game was procured by poaching, or that the implements were used, the poacher may be fined in a penalty of £5, besides forfeiture of the game, and guns, nets, and other implements which he may have so used. The constable may also stop and search any cart in which he suspects there may be such game or implements. The person convicted may appeal, if he chooses, to the next Quarter Sessions, or, in certain cases, to the Court of Queen's Bench. A conviction can be obtained only in cases of actual seizure, but for a conviction it is not necessary that the poacher should be seen actually committing the offence.

As game is in the category of wild animals, the poacher is entitled to keep the game, except where it was both started and caught on one and the same person's lands. But the game may be taken from the poacher if the demand is made at the time on the land or on fresh pursuit. The law of Scotland does not materially differ from that of England, as to poachers; and the Night-poaching Act applies to it equally as to England. The Scotch Day Trespass Act (2 and 3 Will. IV. c. 68) closely agrees with the English act. But it is singular that in the case of night-poachers the game cannot be taken from the poacher, even when caught in the act and on the lands; though it can be so in England (*Oke's Game Laws*, by Bund, seventh edition, 1877, page 360; and for Ireland, page 407). The act conferring power on constables to stop and search poachers on the highway also extends to Scotland. In England the poaching of hares or rabbits by night in preserves is a misdemeanor; whereas it is only an offence punishable summarily in Scotland. On the other hand, it is not necessary for seizure by day in Scotland that the game should be recently killed. In Ireland the law as to poaching is not identical with the law of England, but substantially the law is the same. The Irish statute against trespass in pursuit of game is 37 Geo. III. c. 35. The law of the United Kingdom has often been described as too severe against poachers, inasmuch as most of the penalties, except in Ireland, are cumulative. But it is answered, that poaching is in reality only stealing under a milder name, game being as much the fruit of the soil as apples or turnips, and that the transition from habitual poaching to stealing is not only easy but inevitable. The partial administration of the law by justices, many of whom preserve game, is also objected to. As regards Scotland, this objection has been removed by the Game Laws Amendment Act, 1877, 40 and 41 Vict. c. 28.

2. *Poaching Fish* is the unlawfully entering on another's fishery in order to catch fish. The law of fisheries is not uniform in the United Kingdom. In England the general rule is that any one of the public may fish freely in the sea and in all navigable rivers; and where he can fish, he can catch salmon as well as every other kind of fish. But there is an exception to this generality, which consists in this, that as the crown could before Magna Charta (which took away such right) legally grant a several or exclusive fishery in the sea or a navigable river to an individual, and as this was, in point of fact, often granted, it follows that it is not uncommon to find, even at the present day, an individual, generally the lord of an adjacent manor, still claiming a several fishery in these places. If he can prove that he has exercised this exclusive right as far back as one or two centuries, it will be inferred that his right dates from before Magna Charta, and therefore will be legal. When such is the case, the public have no right to fish even in a navigable river or the sea at the specified places, the sole fishery being vested in this individual owner. In streams not

navigable, the rule is, that each riparian owner—i. e., the owner of the lands on the bank of the stream—has a right to a several or exclusive fishery up to the middle line of the stream. If he is owner on both sides of the stream, then he has the exclusive fishery in the whole of the stream, so far as his lands extend. As to ponds, whoever is owner of the soil, is the owner of a several fishery there, unless he has let it to another. As to lakes, it is not clearly ascertained how the fishery is to be divided between the owners of the lands abutting thereon; but much will depend on the title to the lands and the subsequent user.

As a general rule, there is no such thing as a right in the public to fish anywhere except in a tidal river or the sea, and that is subject to the exception of an individual claiming a several fishery, as before mentioned. It is often supposed that, at all events, if a highway adjoins a private stream, any one may fish in the stream or angle there; but this is a delusion. Nobody is entitled to use a highway for the collateral purpose of either fishing or poaching, the use of the highway, so far as the public are concerned, being confined to the purposes of traveling or transport. The general rule as to all several, i. e., exclusive fisheries is, that whoever goes and poaches the fish commits an offence, for which he may be summoned before justices, and fined £5, over and above the value of the fish taken; and if the fishery where he poaches is adjoining the dwelling-house of the owner of the fishery, it is a still higher offence, for it is then an indictable misdemeanor. The Poaching Code of England is contained in the Larceny Act, 1861. It is immaterial what kind of fish is caught by poachers, and how they are caught. But a milder punishment is awarded to the poaching angler, for even though he poach in a fishery adjoining the owner's dwelling-house, he incurs only a penalty of £5; and where the fishery does not adjoin a dwelling-house, he incurs a penalty of only £2. Whenever a fish-poacher is caught in the act of poaching, he may be at once apprehended, not only by the owner of the fishery, but by anybody; but this can only be done while he is on the spot or near it, for if he escape to the highway or to other lands before being arrested, he cannot then be apprehended, but can only be summoned before justices in the usual way. In this respect, a privilege is given to anglers, for in no case can these be arrested, if angling during the daytime; they can only be summoned for the offence. The poacher, when arrested, must be taken within a reasonable time before a justice of the peace and charged with the offence.

Though anybody may arrest the fish-poacher, still it does not follow that the fish poached can be taken from the poacher; on the contrary, the rule is the same as with reference to game, that whoever first catches the fish, whether legally or illegally, is entitled to keep it; and though game can on certain occasions be taken from the poacher, this is by reason of an express provision in the Game Act; but there is no similar provision as to poached fish, so that the poacher, whatever other punishment he may incur, does not lose his fish. With regard, however, to the poaching implements, such as nets, it is provided by an express section of the Larceny Act (24 and 25 Vict. c. 96, s. 25), that the owner of the fishery or land where the poacher is caught, or his servant, may demand, and if refused, may seize the net, rod, line, hook, or other implement used for taking the fish, but no other person can seize these. It may also be observed that the English Salmon Fishery Act (24 and 25 Vict. c. 109), though singling out salmon from all other fish for peculiar protection, does not deal specially with poachers. Its chief object is to restrain the owners of salmon-fisheries themselves from fishing at certain times and by certain means, for which purpose, a close season is declared, during which no person, whether otherwise entitled or not, can legally catch salmon. Of course, poachers are prohibited from catching salmon at the times and by the means forbidden to the owner, and in this sense come within the Salmon Acts. Thus, all persons are prohibited from poisoning salmon-rivers, from fishing salmon with lights, spears, gaffs, stroke, hails, or snatches; using fish-roe as a bait; selling or buying salmon-roe; using nets having meshes larger than two inches; from using fixed engines, fishing without a license, &c. Large powers to arrest are given to water bailiffs acting under the Freshwater Fisheries Act, 1878, 40 and 41 Vict. c. 39. These, under the Salmon Fisheries Acts of 1865 and 1873, had formerly been confined to salmon rivers.

The law of Scotland differs considerably from that of England. In Scotland the fundamental rule is that no person is entitled to fish salmon (even by angling) unless he can produce a grant or charter from the crown, conferring upon him such right. Nearly all the great landed proprietors are in possession of such rights as pertinent to their lands. And the crown's original right to the salmon applies not merely to rivers, but to the sea-coasts all round Scotland. Hence the public have no right to fish with nets even in the sea, except by leave of the crown, or its grantee at the spot in question. Where a salmon-river belongs to several proprietors, the rule is that none can fish by using fixed engines; but the only legal mode is the mode of fishing by net and coble (or boat). As regards poachers of salmon, the law is contained

in the act 7 and 8 Vict. c. 95. By that law, whoever poaches salmon in a river, lake, or within a mile of the sea-shore, incurs a penalty of £5, besides forfeiting the boat, net, or other engine used in catching the fish. While the law is as above stated with respect to fishing salmon with nets, even a grant from the crown is required to enable a riparian owner to angle for salmon. Hence the right of angling for salmon is not a pertinent of the property in the banks, and each owner is not entitled to angle up to the middle of the stream. Anglers, although riparian owners, or who have a permission from such, are therefore all poachers, and incur a penalty. The Scotch Salmon Acts, 25 and 26 Vict. c. 97, 27 and 28 Vict. c. 118, 31 and 32 Vict. c. 123, also forbid owners of fisheries and others fishing salmon by fixed engines, during close-time, &c. As regards other fish than salmon, the general rule is, that the riparian owner is entitled to catch all the fish he can, provided he do not interfere with the superior right of some crown grantee of the salmon-fishery.

A person who poaches trout or other fresh-water fish with a net, or by double-rod fishing, or cross-line fishing, or set lines, &c., incurs a penalty of £5, besides forfeiture of the fish caught. And he may be arrested if he is net-fishing, but not if he is fishing in another way. Moreover, a mere angler of trout, though a poacher, cannot be arrested, nor yet punished by any penalty; though he is liable to an action at law, which, however, is virtually no remedy at all. So, in the case of all poachers of trout (except angling poachers, who can neither be arrested, nor yet have their fish or fishing-rod taken from them by force), the owner of the fishery, or any person authorized by him, may seize the nets, boats, and fishing implements, if the poachers are found on the spot. See the Freshwater Fisheries (Scotland) Acts, 8 and 9 Vict. c. 26, and 23 and 24 Vict. c. 45. Though the poaching angler is only liable to an action, yet the poaching angler of salmon may be fined. The public have no right to angle from a highway adjoining a stream. Where a stream runs through a farm, the farmer has no right to angle for trout, unless the lease expressly allows it; but he cannot fish for salmon with a net, or even by angling, for it interferes with the crown grantee, if there be one. It has also been held that he cannot fish for trout with a net; but this decision is supposed to be doubtful, and would probably be qualified, if the point were raised. There are special salmon statutes for the river Tweed, and for the Solway and the Scotch rivers running into these, and for some other rivers; but these statutes do not substantially differ from the general law. In Ireland the law of poachers of fish is the same as in England in all the main points. See Paterson's *Fishery Laws*; and Oke's *Fishery Laws*, by Bund, second edition, 1878.

POCAHONTAS, the legendary 'Princess Pocahontas,' born about 1595, was the daughter of an Indian chief of Virginia. It is due to the vanity of Captain John Smith, a bustling early settler, that this red Indian woman has been embalmed in his fragmentary story as a heroine of romance, in that she died of love for the said John Smith, years after she had prevented her father's braves from beating out his brains at the imminent risk of a similar visitation on her own; a fond imagination perpetuated in sculpture by Capellano, as may be seen any day over one of the doors of the Capitol at Washington. But Mr. E. D. Neill, U. S. Consul at Dublin, has recently dispelled the halo from the brow of this 'Blessed Pocahontas, and Great King's daughter of Virginia.' According to evidence adduced by this gentleman, P. first appears in history tumbling wheels in the market-place of the English fort—a prototype of our city Arabs. Next she is living with a volunteer captain called Cookham. Subsequently separate from him, she is betrayed by her uncle Patowomek (Potomak?) to Captain Argall, the unscrupulous deputy-governor of Virginia, and held by him as a hostage for the purpose of extorting from her father such terms as he required. In pursuance of this plan, John Rolfe, a married Englishman, marries her. Sir Thomas Dale, the governor, afterwards brings the 'Virginian Princess' to England, as a means of extracting money from the government of James I. for the plantation. She created a sensation of curiosity in London and at court, and died at Gravesend in 1616, aged 21. The son she bore to John Rolfe returned to Virginia. Richard Randolph, son of an 'esteemed and industrious mechanic,' is said to have married Jane Bolling, the great granddaughter of P., who is accordingly proudly referred to as an ancestress of the Randolphs and other distinguished families of Virginia. See *English Colonization of America*, by E. D. Neill (1871).

PO'CHARD (*Fuligula*), a genus of ducks of the oceanic section (see DUCK), having the bill as long, or nearly as long as the head, broad and very flat, a little dilated towards the tip, the lamellæ of the upper mandible not projecting beyond the margin, the wings and tail short, the tail rounded. The windpipe of the male in all the pochards, terminates in a labyrinth composed partly of bone and partly of membrane. There are numerous species, some of them natives of the arctic regions; some found, at least

in winter, on the coasts of most parts of Europe, Asia, and North America; and some in the southern hemisphere.—The COMMON P. (*F.*—or *Nyroca—ferina*), also known as the DUN BIRD, and as the Red-headed Plover and Red-eyed Plover, is a frequent winter visitant of Britain. It breeds in very northern regions; and is abundant in all of them, but in winter migrates southwards, in America as far as Carolina and Louisiana, whilst in Asia it has been found even in Bengal. It is smaller than the mallard, but rather larger than the wigeon. The head and neck are bright chestnut, the eyes red, characters which at once distinguish it from every other British duck. It is highly esteemed for the table. Great numbers are sold every winter in the London market.

Pochard (*Fuligula ferina*).

—Several other species are reckoned among British birds.—The TUFTED DUCK (*F. cristata*) is a frequent winter visitant of the bays, estuaries, and lakes of Britain. It is a plump and short bird; black, with a white bar on the wing; the breast, belly, and sides white. The occipital feathers are elongated. The CANVAS-BACK DUCK (*F. Valisneria*) of North America is a species of pochard. It is very like the Common P., but is much larger, and

Canvas-Back Duck (*Fuligula valisneria*).

has the bill higher at the base, and less dilated towards the tip. The upper parts are also whiter. The Canvas-back Duck breeds in the northern parts of America, and migrates southward in flocks in autumn. It winter, it abounds particularly on the Chesapeake and its tributaries, and is also common southward to New Orleans, often collecting in very large flocks, particularly towards evening. It is very shy, but vast numbers are killed, it being in very high esteem for the excellence of its flesh.

PO'CO (Ital.), a little, a term much used in Music, as *poco animato*, rather animated; *poco forte*, abbreviated *pf.*, rather loud; *poco a poco*, signifies by degrees, little by little; *poco a poco crescendo*, becoming loud by degrees; *poco a poco rallentando*, becoming slower by degrees.

POD. See LEGUME.

PO'DAGRA. See GOUT.

PODA'RGUS, a genus of birds of the family *Caprimulgidae*, nearly allied to the true Goat-suckers (q. v.), but having no connecting membrane at the base of the toes, and the middle toe not pectinated. Some interesting species are natives of Australia, strictly nocturnal in their habits, and remarkable for the difficulty with which they are roused from their sleep by day. *P. humeralis* may be pushed off a branch, and seems scarcely to waken so as to save itself from falling to the ground; and if two are sitting together, as is usually the case, one may be shot without its mate being much disturbed. But by night this bird is all activity.—Another species, *P. Owieri*, disturbs the night by a hoarse cry, resembling the syllables *More Pork*, by which name it is therefore known in New South Wales.

PODE'STÀ (Lat. *potestas*, power), an Italian municipal magistrate. The name was first applied to foreign magistrates with supreme authority, whom the Emperor Frederick Barbarossa placed over the Italian towns on subjugating them. In the 13th and 14th centuries, an officer bearing the same designation appears at first occasionally, like the Roman dictator, afterwards in

most Italian cities as a permanent magistrate, appointed either by the constituent parliament, or by the Great Council; he superseded all the ordinary magistrates, the military officers, and occasionally the judges. The cause of appointing such an officer was the jealousy that subsisted between the richer citizens and the nobles; the podestà was a stranger, generally belonging to the nobility, and prohibited, during his term of office, from forming any intimate connections in the city which he governed. His chief duty was the execution of summary justice on the lawless barons; and in the great Lombard towns, he generally obtained a predominance for the citizens. Occasionally, however, the podestà became too strong for both parties, securing his re-election during a succession of years, and becoming the despotic ruler of the city.

Podestà is the name now given in many Italian towns to an inferior municipal judge.

PODGORI'TZA, a town of Montenegro, in the district ceded to Montenegro by Turkey in terms of the treaty of Berlin. It is a fortified town, and has a population of about 7500. P. is about 35 miles north of Scutari.

PO'DICEPS. See GREBE.

PODIEBRAD AND KUNSTAT, GEORGE BOCZKO OF, son of Herant of Kunstat and Podiebrad, a powerful and influential Bohemian noble, of the Hussite party, was born in 1420. While still a youth, he threw himself, with all the ardor and resolute force of his nature, into the Hussite struggles. Like the rest of his family, however, he adhered to the moderate party of the Hussites during the government of King Sigismund; but when, on the death of that monarch, the Catholic barons (1438) carried the election of Albrecht V. of Austria (II. of Germany), P. allied himself with the Utraquist Orders in Tabor, and offered the sovereignty of Bohemia to Casimir, king of Poland. Albrecht immediately declared war against him, and invested Tabor, but was forced by P. to raise the siege, and retire to Prague. From this time, P.'s influence was firmly established among the Utraquists; after Lipa, he was the first man of the party. When Albrecht died in 1439, Lipa was appointed regent during the minority of the new king Ladislas; but five years later, Lipa himself died, and P. obtained the government of the country. He, however, was not satisfied. His ambition was to acquire the royal dignity. In 1449, he one night seized the capital, drove away all the Catholic barons, and even imprisoned his colleague in the regency, Meinhardt von Neuhaus. This outrage led to a year or so's fighting—the final result of which was that P. was acknowledged governor or regent by the whole of Bohemia. On the death of Ladislas in 1457, P. managed to get himself chosen his successor, and was crowned 7th May 1458.

From this period he began to display the full power and strength of his administrative genius. He reorganized the forms of education and religion, and strove to bring about a peaceful settlement of the religious dissensions that had desolated the land. He even went the length of respectfully soliciting the papal co-operation in his humane endeavors; but his Holiness would have no dealings with this Samaritan ruler, and in December 1463 publicly proclaimed him a heretic. All the neighboring princes sent letters to Rome, exhorting or imploring the pope to moderation; but the only answer which Pius II. gave them was placing P. under the ban of the Vatican. Shortly after, Rudolf, the papal legate, excited the Catholics of Bohemia to insurrection. P. tried every means of conciliation but in vain. In September 1466, a German Catholic army burst into Bohemia, but this host of pseudo-crusaders was annihilated at Riesenberg. Once more Pius excommunicated P.; and in addition, he induced Mathias (q. v.) of Hungary to invade Moravia. The Bohemian king appealed to a universal council, but he also prepared to meet force with force. Summoning back from abroad the banished Taborite warriors, he crushed the insurrection, and compelled his enemies to grant him an advantageous armistice. In 1467, his son Victorin, on the renewal of hostilities, invaded and devastated Austria, while the Hungarians who had invaded Bohemia were surrounded at Vilemov, and forced to cease from hostilities. In spite of the magnanimity shown by P. on this occasion, Mathias acted falsely towards him, and in the following year had himself crowned king of Bohemia and Markgraf of Moravia. P. instantly summoned the Bohemian diet, and proposed to the assembled orders that they should take the king of Poland as his successor, while his own sons should merely retain the family possessions. By this means, he obtained the Poles for allies; the Emperor Friedrich also declared in his favor, while his Catholic subjects were reconciled to him, so that the Hungarians found it advisable to conclude a peace. P. died 22d March 1471. His sons, Victorin and Henry of Münsterberg, fell back into the ranks of the Bohemian aristocracy; but in the stormy days that followed, they rendered good service to their native land.

PO'DIUM, a pedestal continued horizontally, so as to form a low wall on which columns may be set. Like the pedestal, it has a base, a die, and a corona, all continued. When the podium breaks

forward so as to form a pedestal for a column, it is called the *Stylobate*.

PODOCARPUS, a genus of trees of the natural order *Coniferae*, suborder *Taxineae*, the order *Taxaceae* of some botanists. The leaves, like those of the allied Ginkgo tree have a remarkable resemblance to the fronds of ferns. The species are natives of New Zealand, the South Sea Islands, and the Indian Archipelago. Some of them are valuable timber trees. *P. cupressina* is one of the best timber trees of Java. It is found also throughout the neighboring islands and the South Sea Islands. It is a beautiful tree, 50 to 80 feet high, with spreading pendulous branches; the wood is yellowish, and takes a very fine polish. *P. totarra*, the **TOTARRA** or **TOTARRA PINE**, is the most valuable timber tree of New Zealand. It grows in the southern parts of New Zealand, and its trunk has been known to attain a diameter of fully 12 feet. Its wood is equal to the best Baltic pine in durability and for ship-building. The wood of *P. elatus*, the **GAGALI** of the Fijians, is peculiarly elastic.

PODO'LIA, or **KAMINETZ**, a government of West or 'White' Russia, north of Bessarabia, and bordering on the Austrian frontier. Area, 16,170 sq. m.; pop. (1880) 2,469,500. The surface is a table-land, strewn with hills, and containing many beautiful districts. Nearly three-fourths of P. is either arable or available for pasturage. Great quantities of corn and fruits, especially melons, are produced, and the fine climate is also favorable to the growth of the vine and mulberry. Hemp, flax, and tobacco are cultivated with success, and the rearing of bees is an important branch of industry. So rich and strong is the grass in the pastures or prairies, that the cattle, of which there are immense herds, can hide themselves from view in it. The population is composed of various races, who live altogether unmixed. The Russniaks (formerly 'serfs') make up the majority, and number over a million; next come the Cossacks; and then the Jews, who are almost all traders. The aristocracy are Poles; the officials and soldiery, Russians.

PODOPHTHALMA (Gr. stalk-eyed), a name often applied to a section or sub-class of Crustaceans, part of the *Malacostraca* of Cuvier, including the orders *Decapoda* (Crabs, Lobsters, &c.) and *Stomatopoda* (Shrimps, &c.). A distinguishing character, from which

Sentinel Crab.

they derive their name, is their stalked and movable eyes. The stalks of the eyes are short in many, but very long in some, of which a beautiful example is presented by the Sentinel Crab of the Indian Ocean.

PODOPHYLLIN is the name commonly given to the resin obtained by means of rectified spirit from the root of *Podophyllum peltatum*, or *May-apple*, a plant common throughout the United States. This resin, which occurs as a pale greenish amorphous powder, has (as well as the root from which it is derived) been introduced into the new British Pharmacopoeia, in consequence of the general favor which it has experienced during the last three or four years from the medical profession in this country. It is an active purgative, and seems to have the power of relieving the liver by exciting copious bilious discharges. As its activity seems to vary in different patients, it is better to begin with a small dose of half a grain, which may be combined with extract of henbane, with the view of preventing its griping. It is likely to prove one of the most valuable additions to our pharmacopoeia.

PODOPHYLLUM, a genus of plants variously ranked by botanists in the natural order *Ranunculaceae*, or made the type of a small distinct order, *Podophylleae* or *Podophyllaceae*, differing from *Ranunculaceae* chiefly in having a solitary carpel. The genus P. has 3 sepals, 6 to 9 petals, 12 to 18 stamens, a broad round stigma, seated almost on the top of the germen, and a many-seeded berry. *P. peltatum* is a perennial plant, with a solitary white flower in the axil of the two leaves; the fruit oval, an inch and a half long, smooth, yellowish, succulent, having a mawkish sweet and subacid taste. It is common in North America, growing in moist woods and on the shady banks of streams, and is known as **MAY-APPLE**, because it flowers and ripens its fruit very early in summer, also as **Hog-apple** and **Wild Lemon**. The fruit

may be eaten, but is not agreeable. All the other parts are actively cathartic. See **PODOPHYLLIN**.

PODURA, a genus of small wingless insects of the order *Thysanoura* (q. v.), having a linear or cylindrical body, a distinctly articulated thorax, rather long antennae, and a long abdomen, terminating in a tail, which divides at its extremity into two branches. They bend the tail beneath the abdomen, and by suddenly extending it, make prodigious leaps. Hence their popular name, **SPRING-TAIL**. The species of this and

Podura villosa.

allied genera are numerous, and some are found on plants, some under stones and in other damp places, some on the surface of stagnant waters. Their bodies are covered with scales, which are extremely interesting objects, and are among the favorite test-objects for the powers of microscopes.

POE, **EDGAR ALLAN**, perhaps the finest and most original poetical genius as yet produced by America, was born at Boston, February 19, 1809. His father, the son of General Poe, a distinguished officer in the revolutionary army, was educated for the law, but, falling in love with a beautiful English actress, he married her and went himself upon the stage. In a few years the youthful couple died within a very short time of each other of consumption, leaving three children entirely unprovided for. Edgar, the second child, was adopted by Mr. John Allan, a rich merchant, who had no children of his own. In 1816 the boy came to England with Mr. and Mrs. Allan, and was sent to a school at Stoke Newington. In 1821 he returned to America, and attended an academy at Richmond in Virginia. In 1826 he entered the university of Charlottesville, where he was a very successful student, but quitted it at the end of a year, deeply involved in debt, chiefly incurred through his strong passion for gaming. For a year or two he now remained quietly at home; the story of his having gone to assist the Greeks in their heroic efforts to throw off the yoke of their Turkish oppressors has no other foundation than the fact that his elder brother, who had gone to sea, got into some trouble with the police at St. Petersburg, from which he was rescued by the American minister.

In 1829 Poe published a volume of poems, his first known essay in literature, under the title of *Al Aaraaf, Tamerlane*, and other poems. He now expressed a wish to enter the army, and Mr. Allan exercised his influence to secure him a cadetship in the Military Academy at West Point. Here he grossly neglected his duties, drank to excess, and was finally cashiered on March 6, 1831. In the same year he published an enlarged collection of his poems, dedicated to the United States Corps of Cadets. Upon leaving West Point, Poe returned to Richmond, and was kindly received by Mr. Allan, who had become a widower and married a second wife. It is related that Poe's conduct to this lady was such that Mr. Allan had to eject him from his house, but there is some reason to hope that this is mere calumny. It is certain, however, that Mr. Allan had some strong reason for displeasure with Poe, and at his death in 1834, he left him unmentioned in his will. Thus thrown upon his own resources, Poe devoted himself to literature as a profession. In 1833 the publisher of a Baltimore magazine having offered prizes for the best prose story and the best poem, Poe competed, and won both prizes. This led to his friendship with Mr. John P. Kennedy, one of the prize committee, who procured him literary employment in connection with the *Southern Literary Messenger* at Richmond. While there, Poe married his cousin, Virginia Clemm, a beautiful and saintly creature, as destitute as himself, who died in 1848. In 1837 he removed to New York, where he lived by contributing to the *New York Quarterly Review* and other periodicals, and where in 1838 he published *The Narrative of Arthur Gordon Pym*. In 1839 he became editor of *The Gentleman's Magazine* at Philadelphia, and published a collection of his best stories with the title, *Tales of the Arabesque and Grotesque*. The next few years were spent in similar literary employment, chiefly at New York; the year 1845 being marked by the appearance of his famous poem, *The Raven*, and 1848, by the publication of *Eureka, a Prose Poem*, in which he endeavored to elaborate a system of cosmogony.

In 1849 he went to Richmond, and it is said became engaged to a lady of considerable fortune. On the 4th of October he left Richmond by train, which he quitted at Baltimore. Some hours later he was discovered insensible in the streets, and taken to the hospital, where he died on October 7. The ordinary explanation of his condition at Baltimore is that he had met some old cronies, and drunk himself into a state of helpless intoxication.

Scarcely any such dark and disastrous career as that of Poe has a place in all the sad records of genius. From the sins and aberrations of a creature so obviously abnormal, we need not seek to 'point a moral.' There is no doubt that Griswold in his life of Poe has been guilty of imputing to him a most exaggerated state of moral depravity; but the fact remains, that the failure of his

life was mainly owing to his habits of frantic dissipation. There was about Poe a strange fascination; his friends loved him—those best who best knew him, and knew him in his wretchedest aberrations. By his wife and her mother he was regarded through all with an obstinacy of tender affection, not for an instant to be shaken.

Whatever may be thought of his morals, of his genius there will be little question. Slight in substance as for the most part it is, small in quantity, and in range limited, there is that in his poetry which ranks it above everything of this kind which his country has hitherto produced. Save for some traces of imitation in its earlier specimens, his verse is eminently a peculiar and individual product. In keen, clear, lyrical quality, the music of Poe at his best is scarcely surpassed by that of any other poet. Many of his short prose tales are wildly and weirdly impressive, though too frequently indulging by morbid preference in ghastly and painful effects. Over very much that Poe has written, alike in prose and in verse, there broods a significant shadow of misery and hopeless portentous gloom. A much more favorable view than usual of P.'s character is taken by Mr. Ingram in the memoir accompanying his edition of P.'s works (4 vols., Edin. 1874); as also in his separate biography, *Edgar Allan Poe, his Life, Letters, and Opinions* (1880). Mr. Stoddard prefixed a memoir to a collection of his poems (1875).

POERIO, CARLO, a noble Italian patriot, was born on the 10th of December 1803. His father, Giuseppe P., Baron Belcastro, was also highly distinguished for his love of liberty and for his sufferings in her cause. Born at Belcastro, in Calabria, in 1775, he took part in the Neapolitan revolution of 1799, and suffered imprisonment on its suppression, but was released in 1803. He also took part in the revolution of 1820, for which Ferdinand handed him over to the Austrians, who assigned him as a place of abode, first Grätz, in Styria, and afterwards Florence. On the recall of the exiles by Ferdinand, in 1833, P. returned to Naples, where he spent the rest of his life, and died 15th August 1843. He left two sons, the elder, Alessandro [born in 1802, celebrated as a poet and patriot, and died (of amputation of a limb) after the battle of Mestre, 27th October 1848], and Carlo, the subject of our notice. Carlo was educated with great care under the parental roof, and trained even from infancy, by the example of his father and brother, to place the love of his country above every other affection. In 1828 he joined the liberals of Naples, and took part in the conspiracy of Avellino, for which he was imprisoned until March 1833. He was concerned in the attempt made in 1847 to extort liberty, but was discovered, and after the movement at Reggio was sent back to prison with D'Ayala, Bozzelli, De Angustinis, Assanti, and others. The revolution in Sicily, which broke out at Palermo on the 12th January 1848, set him at liberty, and he immediately gave himself to the organization of the famous demonstration of the 27th January 1848, which was destined to produce the constitution of the 10th February. Carlo was successively nominated Director of Police, and Minister of Public Instruction; but he soon resigned, and also refused the rank of Privy Councillor, offered to him by Ferdinand. He was appointed deputy to the parliament.

On the 18th July 1849, an unknown hand left in P.'s house a note to the following effect: 'Flee without a moment's delay. You are betrayed. Your correspondence with the Marquis Dragonetti is in the hands of the government.' As there had been no such correspondence, and as it was P.'s wish to maintain the combat to the last on the ground of legality, he did not flee. On the following day he was arrested, and his house was ransacked. Six days after, a letter of Dragonetti's was given him to read, in which he spoke of an invasion by Garibaldi, instigated by Mazzini and Palmerston. The letter was a forgery of the police! P. compared it with other authentic letters of Dragonetti, and proved it to have been forged. As the government could not bring him to trial on that pretext, it had recourse to a spy, Jervolino, who accused P. of being at the head of a sect—which never existed—called the Italian Unity, which aimed at proclaiming a republic, and murdering the king and the ministers. P. demanded to be confronted with Jervolino, but this was refused. When this accusation also fell to the ground, Peccheneda, who was at the head of the police, tried to induce the others who were indicted for political reasons to denounce P. as a revolutionist, promising them liberty as the reward. His design partly succeeded. He extorted from Romeo the printer, and from Margherita some false accusations, which the fear of death caused those unfortunate persons to make. But they were of no avail, and recourse was again had to the accusation made against P. by Jervolino; and although P. brought forward many clear proofs that the informer was paid by the police to do him harm, the court paid no attention to that, nor to any other of his objections, and concluded by inflicting on him the penalty of passing 24 years in irons, and of a heavy fine.

Thus Carlo P., a minister, and a member of parliament, a man of rare genius and of exemplary life, was cast into the hulks at

Nisida, dressed as a felon, and dragging 15 pounds of chains; and thence, through the suspicions of the government, who dreaded his escape, he was conveyed from hulks to hulks, from Nisida to Procida, from Ischia to Montefusco, and finally to Montesarchio. Assassins and thieves were given him as companions in order to humble him, as if the virtue of the truly great man could be sullied by the presence of miscreants and cut-throats. He indignantly spurned the proposal to petition for his liberty.

The protests of the English and French diplomatists against the iniquitous state trials, which had been instituted in Naples with the sole object of condemning persons obnoxious to the king; the letters of Mr. Gladstone; the constant dread of a popular rising on behalf of the condemned political offenders, and especially of P., disturbed the mind of Ferdinand II. to such a degree that he sought some means of ridding himself of the prisoners of Montesarchio. Having failed in every attempt to force them to ask pardon, he resolved to send them to America. On the 19th January 1859, P. and 66 other prisoners, among whom were Settembrini, Spaventa, Pica, the Duke of Castromediano, Braico, Schiavoni, Argentino, Pace, Danis (all of whom became members of the Italian parliament), were conveyed to Pozzuoli, and put on board of the *Stromboli*, which immediately set sail for New York. When they reached Cadiz, P. and his companions were put on board an American vessel, the captain of which, however, was induced to land them at Cork, whence they returned, by London, to Turin. In the following year P. was elected deputy by two colleges in Tuscany, and took his seat in parliament.

When Garibaldi (q. v.) had driven out the Bourbon dynasty, P. returned to Naples. He declined the ministerial office offered to him by Cavour, and also the governorship of the southern provinces proposed to him by Constantino Nigra, but accepted the office of privy councillor. The privy council elected him its vice-president; then, being re-elected deputy, he was proclaimed vice-president of the parliament. He died in April 1867.

POET-LAUREATE. See LAUREATE.

PO'ETRY (from the Greek *poieo*, to make, or to create), according to the mere etymology of the word, signifies a creation or production of any kind; but its classical equivalent, *poiesis*, was applied by the Greeks almost exclusively to designate the artistic productions of the imagination, expressed in language. Poetry is thus not necessarily associated—as many people seem to think—with verse or rhyme. It may find expression in prose, and in point of fact has often done so, both in ancient and modern times. The Book of Ruth, for example, is decidedly poetical in substance, yet in form it is strictly prosaic. The same may be said in a still more remarkable degree of the Book of Job and the Prophetical Writings, as they appear in our English version. Jeremy Taylor, Hooker, Rousseau, Burke, Carlyle, Ruskin, Hawthorne, Emerson, and other modern prose writers, are often as richly or profoundly imaginative as poets by profession; but although the essence of poetry lies rather in the nature and adornment of the thoughts expressed than in the form of the composition, yet in general it has subjected itself to certain rules of *metre* or measure, and often also to rules of *rhyme*. The reason of this practice lies in the fact that the music so produced by the mere words is found to heighten the emotions which their meaning is calculated to produce, and thus furthers the end that the poet has in view. It is from this circumstance that the term poetry has become almost synonymous with metrical composition.

Poetical compositions are of several kinds or classes, to which particular terms are applicable; the principal are the Epic (q. v.), the Lyric (q. v.), and the Drama (q. v.). To the first of these belongs the Ballad (q. v.); to the second belong the Song (q. v.) in all its varieties, serious and comic, the Hymn (q. v.), Ode (q. v.), Anthem (q. v.), Elegy (q. v.), Sonnet (q. v.), &c.; the third embraces Tragedy and Comedy. Besides these three principal kinds, others of less consequence may be mentioned, such as Didactic Poetry (q. v.), Satirical Poetry (see SATIRE), in which, however, imaginative and ideal elements in general mingle so sparingly that the stricter kind of critics exclude them from the circle of poetry altogether. The theory of P., or Poetics (a branch of Aesthetics, q. v.), has been largely discussed in every cultivated language. Histories of the P. of the several nations are numerous: Rosenkranz and Zimmermann have given us universal histories of poetry.

POGGE (*Aspidophorus Europæus*), a fish of the family *Sclerogasteridae*, or *Mailed Cheeks*, and nearly allied to the Bullhead (q. v.), but having the body cuirassed with large bony scales from the head to the tail, so that it is in form nearly a pyramid with eight faces. The head is thicker than the body, with points and depressions, the snout furnished with short recurved spines. The P. is also known on the coasts of England as the *Armed Bullhead*; and on the coasts of Scotland by the names *Lyrie*, *Pluck*, and *Noble*. It is pretty common on the British coasts. It is seldom

more than six inches long. Notwithstanding its uncouth appearance, its flesh is good.

POGGENDORF, JOHANN-CHRISTIAN, a German physicist, was born at Hamburg, 29th December, 1796. He studied pharmacy, chemistry, and physics; and was professor of physics at Berlin from 1834 till his death. In 1838 he became a member of the Academy of Sciences. His chief discoveries were in connection with electricity and galvanism, and these are reckoned of great value; he also invented a multiplying galvanometer for measuring the calorific action of currents. From 1824 onwards he edited the *Annalen der Physik und Chemie*, contributing to this collection many important memoirs. He was one of the triad (Liebig and Wöhler being the other two) who prepared the *Dictionnaire de Chimie* (Brunswick, 1837—1851). The two works published by himself are the *Linien zu einer Geschichte der exakten Wissenschaften* (Berlin, 1853), and *Biographisch-literarisches Wörterbuch zur Geschichte der exakten Wissenschaften* (Leip. 1858—1863, 2 vols.). P. died in January 1877.

POGO'NIAS, a genus of acanthopterous fishes, of the family *Scianidae*, having two dorsal fins, one of them deeply notched, and many small barbels under the mouth. The fishes of this genus are found on the coasts of warm countries; and are remarkable for the sounds which they emit, which somewhat resemble those of a drum, and have obtained for them the name of **DRUMFISH**. It is not known how these sounds are produced; but sailors in vessels anchored near the shore, where species of this genus abound, are often prevented from sleeping, until they have become habituated to them. Some of the species attain a large size, one hundred pounds or more, and are excellent for the table.

POI'NDING (same root as Eng. *pound*), in the law of Scotland, means the seizing and selling of a debtor's goods under process of law, or under the warrant of a *debitum fundi*, in order to pay the debt. It is either real or personal. Real pointing is the attaching of goods or movables on the land over which some real or heritable security exists. It is one mode in which heritable security is made effectual. Thus, the superior of lands can point the ground to obtain payment of his feu duties; and the holder of a heritable bond can do the same in order to recover his debt. Personal pointing is the mode in which a decree of the court is made effectual by the messenger or bailiff seizing the movables of the debtor. They are then appraised or valued, and the messenger reports his execution to the sheriff, or other judge ordinary, who grants warrant to sell the goods by public roup after advertisements. The net amount of the sale is paid over to the creditor, or if no purchaser bid for them, they are delivered to the creditor at the appraised value. There is also another kind of pointing, called a pointing of stray cattle, which takes place whenever the cattle of a stranger trespass on lands, in which case the owner or occupier of the lands can seize them *brevi manu*, and keep them as a security until the damage done by the cattle is paid to the owner of the land. By an old Scotch statute, the owner of the cattle is bound to pay, besides the damage, half a merk for each head of cattle, and for the damage, penalty, and expense of keeping the cattle, the owner of the land can detain the cattle until payment. The pointer must, however, take care to keep the cattle in a proper place, and feed them. In England, the word pointing is not used, the corresponding term being Distraint, or Distress (q. v.).

POINT, in Heraldry, a triangular figure issuing from the dexter and sinister base of the shield. It is common in French and German heraldry, and occurs in the shield of Hanover, which was a part of the royal arms of Great Britain from the accession of George I. till that of our present sovereign. A shield charged with a point is in heraldic drawing hardly distinguishable from one parted per chevron.

Point.

POINT-A-PITRE, a town of the French West India island Guadeloupe, capital of the division of Grande-Terre, on the Little Cul-de-Sac, 20 miles north east of Basse-Terre. The town is well built, and has a safe and spacious harbor. It is the center of the commerce of the colony. Pop. 14,000.

POINT-BLANK. See **GUNNERY**. The point-blank range of a cannon varies from 200 to 300 yards.

POINT DE GALLE, a fortified town and seaport on the south-west extremity of the island of Ceylon, stands on a low rocky promontory of the same name, in lat. 6° 1' N., long. 80° 12' E. The harbor, formed by a small bay, the entrance to which is about a mile in width, is good, although there are numerous rocks, and a pilot is required to conduct vessels to the anchorage. Among the principal edifices, are the fort—a mile in circumference—the old Dutch church, a Roman Catholic chapel, an excellent Orphan Asylum, barracks and light-house, 103 feet above sea-level. This town has become important within recent years, and specially

since the organization of the Peninsular and Oriental Steam-Navigation Company. Vessels plying between Suez and Bombay and Calcutta, Australia, China, Penang, and Singapore, call here to coal and to tranship passengers. It is the seat of government of the southern province of the colony of Ceylon. Gold and silver ornaments, workboxes, &c., are made with great taste and nicety by the native workmen. Pop. (1871) 47,954.

POINTED ARCHITECTURE. See **GOTHIC ARCHITECTURE**.

POINTER, a kind of dog nearly allied to the true Hounds (q. v.), but not reckoned one of them. It is remarkable for its habit of *pointing* at game; its whole body, and particularly its head, indicating the position of the game to the sportsman; and a well-trained P. will remain long immovable in the attitude of pointing, not going forward to disturb the game which its exquisite power of scent has enabled it to discover. It is recorded of two pointers that they stood an hour and a quarter without

A Pointer standing at Game.

moving, whilst Mr. Gilpin painted them in the act. The P., when he scents game, stops so suddenly and completely, that even the fore-foot, already lifted, remains suspended in the air. Without the P., the sportsman would have comparatively little success in the pursuit of grouse; but the dog performs for him the laborious task of 'beating' the wide moors. Well-trained pointers will scarcely point at anything except 'game'; but inferior dogs often point at almost any living creature the odor of which affects their nostrils. The habit of pointing once acquired appears to become hereditary, so that very young pointers often exhibit it in great perfection. It has been explained, with the crouching of the Setter, as 'the natural start of surprise or interest which all dogs give when coming suddenly upon the scent or sight of their natural prey; modified by cultivation, and by transmission through many generations, each, by education, improving upon the capabilities of the former.'—See Bell's *British Quadrupeds*.

The breed of pointers now most common in Britain is believed to be crossed with the foxhound, to which there is considerable resemblance in colors as well as in form. The figure is very muscular, the hair short, the ears pendulous, the upper lips moderately large, the tail pointed and destitute of brush. Dogs of this breed are very active, and capable of long-sustained exertion. The original breed, the *Spanish P.*, probably brought to Spain from the East, is of more bulky form, less active habit, and less capability of continued exertion. The P. is very forward and familiar in its manners, but is both affectionate and intelligent, although it has a reputation of inferiority in these respects to many other kinds of dogs.

POINTS OF THE ESCUTCHEON, in Heraldry. In order to facilitate the description of a coat-of-arms, it is the practice to suppose the shield to be divided into nine points, which are known by the following names: A, the dexter chief point; B, the middle chief; C, the sinister chief; D, the collar or honor point; E, the fess point; F, the nombril or naval point; G, the dexter base point; H, the middle base point; and I, the sinister base point. The dexter and sinister sides of the shield are so called, not in relation to the eye of the spectator, but from the right and left sides of the supposed bearer of the shield.

Points of the Escutcheon.

POISON UDER, POISON IVY, POISON OAKS, POISON SUMACH, AND POISON VINE. See **SUMACH**.

POISONING, SECRET, a mode of taking away life by poisons so slow in their operation that the gradual sinking of the victims under their influence closely resembled the effects of disease or the ordinary decay of nature. It has been practised in all ages, and several undoubted and numerous supposed instances of it are mentioned by Greek and Roman writers. It was not, however, till the 17th c. that this atrocious practice became of frequent oc-

currence; but from this time it rapidly increased, spread over Western Europe like an epidemic, and became gradually a regular branch of education among those who professed a knowledge of chemistry, magic, or astrology. These persons regarded the knowledge of the mode of preparing secret poisons as of the highest importance, and many of them realized large sums by the sale of their preparations, and occasionally of the secret of their composition. It was in Italy and France that this art was chiefly practised and brought to the highest perfection; but it seems also to have prevailed in England to a considerable extent, for we find that, in the 21st year of Henry VIII.'s reign, an act was passed declaring the employment of secret poisons to be high treason, and sentencing those who were found guilty of it to be boiled to death. The only undoubted instance of this crime which appears prominently in English history is the murder of Sir Thomas Overbury (q. v.) by Viscount Rochester (the favorite minion of James VI.) and his wife, the divorced Countess of Essex; though many suppose, and with some show of probability, that James VI. himself was a victim to similar nefarious practices on the part of Villiers, Duke of Buckingham; and undoubtedly such was the popular impression at the time, for Dr. Lamb, a conjurer and quack, who was believed to have furnished Buckingham with the poisons, was seized by the angry populace in Wood Street, Cheap-side, London, and beaten and stoned to death. But it was in Italy where this mode of poisoning was most prevalent. There, judging from the writings of various authors it seems to have been looked upon as a not unjustifiable proceeding to get rid of a rival or enemy by poison; and from the time of the Lombard invasion down to the 17th c., Italian history teems with instances which sufficiently show that poison was both the favorite weapon of the oppressor, and the protection or revenge of the oppressed.

The Borgias are generally singled out and held up to the horror and detestation of mankind; but as far as their poisonings are concerned, they merely employed this method of destroying their adversaries a little more frequently than their neighbors. To show the popular feeling on this subject, we may instance the case mentioned in the memoirs of Henry II., fifth Duke of Guise, of a soldier who was requested to rid the duke of Gennaro Annese, one of his opponents in Naples. *Assassination* was the mode proposed to the soldier, but he shrank with horror from the suggestion, stating at the same time that he was quite willing to *poison* Annese. It was shortly after the date of this story (1648) that secret poisoning became so frequent; and the Catholic clergy, despite the rules of the confessional, felt themselves bound to acquaint Pope Alexander VII. with the extent of the practice. On investigation it was found that young widows were extraordinarily abundant in Rome, and that most of the unhappy marriages were speedily dissolved by the sickness and death of the husband; and further inquiries resulted in the discovery of a secret society of young matrons, which met at the house of an old hag, by name Hieronyma Spara, a reputed witch and fortune-teller, who supplied those of them who wished to resent the infidelities of their husbands, with a slow poison, clear, tasteless, and limpid, and of strength sufficient to destroy life in the course of a day, week, month, or number of months, as the purchaser preferred. The ladies of Rome had been long acquainted with the 'wonderful elixir' compounded by La Spara; but they kept the secret so well, and made such effectual use of their knowledge, that it was only after several years, during which a large number of unsuspected victims had perished, and even then through a cunning artifice of the police, that the whole proceedings were brought to light.

La Spara and thirteen of her companions were hanged, a large number of the culprits were whipped half-naked through the streets of Rome, and some of the highest rank suffered fines and banishment. About half a century afterwards, the discovery was made of a similar organization at Naples, headed by an old woman of threescore and ten, named Toffania who manufactured a poison similar to that of La Spara, and sold it extensively in Naples under the name of *acquetta*, and even sent it to all parts of Italy under the name of 'Manna of St. Nicola of Bari,' giving it the same name as the renowned miraculous oil of St. Nicola, to elude discovery. This poison, now best known as the 'Acqua Tofana' or 'Acqua di Perugia,' is said by Hahnemann to have been compounded of arsenical neutral salts; while Garelli states that it was crystallized arsenic dissolved in a large quantity of water; but both agree that it produced its effect almost imperceptibly, by gradually weakening the appetite and respiratory organs. After having directly or indirectly caused the death of more than 600 persons, Toffania was at length seized, tried, and strangled in 1719. From this time the mania for secret poisoning gradually died away in Italy.

About the middle of the 17th c., this horrible practice seems to have first become prevalent in France, and under similar circumstances, the agents being married women, and their husbands the victims; and as in Italy, the extent to which the practice was carried was first made known by the clergy. The government,

acting on the information thus obtained, seized and imprisoned in the Bastille two Italians named Exili and Glaser, who were suspected of having been the manufacturers and vendors of the poisons. Glaser died in prison; but Exili, becoming acquainted with another prisoner named St. Croix, communicated to him his secret, which the latter made considerable use of after his release, compounding in particular the poison known as 'succession powder,' which subsequently became so celebrated. It was the same St. Croix who played such a prominent part in the tragical history of the Marquise de Brinvilliers (q. v.).

Penan-tier, the treasurer of the province of Languedoc, and the Cardinal de Bonzy, were both pupils of St. Croix, and managed, the one to pave the way for his own advancement, and the other to rid himself of his numerous creditors, by the administration of poison; but the great influence of these men, and the want of direct evidence, barred all proceedings against them. Secret poisoning now became fashionable; the passions of jealousy, revenge, avarice, and even petty spite, were all satisfied in the same way, and as a necessary consequence, other offences decreased in proportion. The prisons teemed with suspected criminals, and the 'Chambre Ardente' was instituted for the special purpose of trying these offenders. In Paris, this trade was chiefly in the hands of two women named Lavoisin and Lavigoreux, who combined with the ostensible occupation of midwife that of fortune-teller, and foretold to wives the decease of their husbands, to needy heirs that of their rich relatives, taking care at the same time to be instrumental in fulfilling their own predictions. Their houses were frequented by numbers of all classes, both from Paris and the provinces, among whom were the celebrated Marshal de Luxembourg (q. v.), the Duchess de Bouillon, and the Countess de Soissons; the two former of these, however, went merely from curiosity. Lavoisin and her confederate were at last discovered, tried, and condemned, and burned alive in the Place de Grève, 22d February 1680; and from 80 to 50 of their accomplices were hanged in various cities of France. So common had this atrocious practice been, that Madame de Sévigné, in one of her letters, expresses a fear lest the term 'Frenchman' and 'poisoner' should become synonymous. For two years after the execution of the two Parisian poisoners, the crime continued to be largely committed, being fostered by the impunity with which offenders of high rank were allowed to escape; and it was not till more than 100 persons had died at the stake or on the gallows, that the government succeeded in suppressing it.

The mania for secret poisoning has not since been revived to the same extent, though isolated instances of its practice have occasionally been discovered, particularly in England, where, within the last 40 years, very extraordinary disclosures have at different times been made of the prevalence of this frightful crime among the laboring classes in several of the rural districts. For further information consult Beckmann's *History of Inventions*, the historians of the period of James I.'s reign, the *French Causes Celebres*, and Mackay's *Popular Delusions*.

POISONS. A poison is commonly defined to be a substance which, when administered in small quantity, is capable of acting deleteriously on the body; but this definition is obviously too restricted, for it would exclude numerous substances which are only poisonous when administered in large doses, as nitre, and the salts of lead, antimony, &c. A person may be as effectually poisoned by an ounce of nitre as by five grains of arsenic, and hence the quantity required to kill must not enter into the definition. Dr. Taylor suggests the following as the most comprehensive definition that can be given: 'A poison is a substance which, when taken internally, is capable of destroying life without acting medicinally on the system;' but this definition is not perfect, for it does not include poisons that act by absorption when applied to a thin and delicate membrane, as glanders, syphilitic poison, &c., or those which must be introduced directly into the circulation by a puncture or abraded surface, as the poison of insects, scorpions, and serpents, the wourai poison, and that of animals suffering from hydrophobia. Omitting, for the present, the consideration of the cases not included in Dr. Taylor's proposed definition, we may consider poisons as divisible into three classes, according to their mode of action on the system—viz., *Irritants*, *Narcotics*, and *Narcotico-Irritants*.

The *Irritants*, when taken in ordinary doses, speedily occasion intense vomiting and purging, and severe abdominal pain. They act chiefly on the stomach and intestines, which they irritate, inflame, and frequently corrode, and may thus occasion ulceration, perforation, or gangrene. Amongst those which possess corrosive properties, are the strong mineral acids, caustic alkalies, corrosive sublimate, &c.; whilst among the pure irritants which exert no destructive chemical action on the tissues with which they come in contact, may be mentioned arsenic, cantharides, carbonate of lead, &c. The *Narcotics* act specially on the brain and spinal cord. Amongst their most common symptoms are giddiness, headache, obscurity of sight or double vision, stupor, loss of

power of the voluntary muscles, convulsions, and, finally, complete coma. Moreover, many of the narcotic poisons present special symptoms, in some cases strongly resembling pure special diseases. Thus there is an almost exact similarity in the symptoms of poisoning by opium and apoplexy, whilst prussic acid and some other poisons give rise to symptoms closely resembling those of epilepsy. These poisons have no acrid, burning taste, nor do they usually give rise to vomiting or diarrhoea, and, excepting a slight fulness of the cerebral vessels, they leave no well-marked post-mortem appearance. They are few in number, and none of them belong to the mineral kingdom. The *Narcotico-Irritants* have, as their name implies, a mixed action. 'At variable periods,' says Dr. Taylor, 'after they have been swallowed, they give rise to vomiting and purging, like irritants, and sooner or later produce stupor, coma, paralysis, and convulsions, owing to their effect on the brain and spinal marrow. They possess the property, like irritants, of irritating and inflaming the alimentary canal. As familiar examples, we may point to nux vomica, monkshood, and poisonous mushrooms. . . . The fact of the symptoms occurring after a meal at which some suspicious vegetables may have been eaten, coupled with the nature of the symptoms themselves, will commonly indicate the class to which the poison belongs. Some narcotic irritants have a hot, acrid taste, such as the aconite or monkshood; others an intensely bitter taste, as nux vomica and its alkaloid strychnia.'

For a notice of the most important rules to be observed by the physician in all cases of suspected poisoning, both with respect to the symptoms and the inspection of the body, we refer to any of the standard works on poisoning, or on medical jurisprudence.

Under the head of *Irritant Poisons* may be included, (1.) Mineral Acids, as sulphuric, nitric, and hydrochloric acids; vegetable acids, and other salts, as oxalic acid, binxalate of potash, and tartaric acid (in doses of half an ounce or more); the alkalies, as pearl-ash (carbonate of potash), soap lees (carbonate of soda), ammonia and its sesquicarbonate; and metallic compounds, as white arsenic (arsenious acid), yellow arsenic (orpiment), corrosive sublimate, bichloride of mercury, penitrate and other salts of this metal, acetate of lead (sugar of lead) in doses of an ounce and upwards, carbonate of lead (white lead), sulphate of copper (blue vitriol), subacetate of copper (verdigris), arsenite of copper (commonly known as *Scheele's green* or *emerald green*, and much employed under the name of *extract of spinach* for coloring confectionery), tartarized antimony, chloride of antimony (butter of antimony), chloride of zinc (Sir W. Burnett's Fluid), nitrate of silver (lunar caustic), sulphate of iron (coppers or green vitriol), and bichromate of potash. (2.) Vegetable Substances, viz., colocynth and gamboge in large doses, savin, croton oil, the leaves and flowers of the common elder (*Sambucus nigra*), &c.; and (3.) Animal Substances, such as cantharides, to which must be added the occasional cases in which sausages, and certain fish and molluscs, usually quite innocuous, act as irritant poisons.

The *Narcotic Poisons* include opium, hydrocyanic (or prussic) acid, oil of bitter almonds, cyanide of potassium, henbane, especially the seeds, alcohol, ether, chloral, and chloroform; while *Narcotico-Irritant Poisons* are nux vomica, meadow saffron (*Colchicum*), white hellebore, foxglove, common hemlock, water hemlock (*Ocotea virosa*), hemlock water-dropwort (*Ethanthus crocata*), fool's parsley, thorn-apple, monkshood or wolf's bane, deadly nightshade, tobacco, Indian tobacco (*Lobelia inflata*), the bark and seeds of the common laburnum, the berries and leaves of the yew-tree, and certain kinds of fungi.

The cases in which they are antidotes qualified to neutralize chemically the action of the poison are few in number. For the *mineral acids* we must prescribe chalk or magnesia in water, with the view of neutralizing them, after which milk should be given freely. The *alkalies and their carbonates* must be neutralized by vinegar and water, or lemon-juice mixed with water, after which milk should be given. For *oxalic acid* the antidote is chalk or magnesia in water, by which an insoluble oxalate of lime or magnesia is formed. For *arsenic*, the hydrated peroxide of iron has been regarded as an antidote, but its efficacy is doubtful. Vomiting should be excited by the administration of a scruple of sulphate of zinc in warm water, and after the stomach has been well cleared out, demulcent fluids, such as flour and water or milk should be given. *Corrosive sublimate* combines with albumen (white of egg), and forms an insoluble inert mass; *nitrate of silver* is neutralized by chloride of sodium (common salt) dissolved in water; *tartarized antimony* is to a great degree rendered inert by the administration of decoction of bark or gall-nuts; and *acetate of lead* is rendered inert by the administration of sulphate of magnesia, which converts it into an insoluble sulphate of lead. In all cases of suspected poisoning, in which the nature of the poison is not known, the safest course is at once to produce vomiting by sulphate of zinc, or in its absence by a dessert-spoonful of flour of mustard suspended in tepid water, and to continue the vomiting till all the contents of the stomach are discharged, after which milk should be given freely.

Most of the known gases—except hydrogen, nitrogen, and oxygen—have a poisonous action when inhaled into the lungs; but in these cases death, if it ensues, is popularly said to be due to *suffocation*, although strictly speaking a person who dies from the effect of carbonic acid, or sulphuretted hydrogen, or of any other noxious gas, is in reality just as much poisoned as if he had taken oxalic acid or arsenic. *Carbonic acid* (q. v.), although seldom employed as an instrument of murder, is a frequent cause of accidental death, and in France is a common means of self-destruction. It is established by numerous experiments that air containing more than *one-tenth* of its volume of carbonic acid, will, if inhaled, destroy life in man and the higher animals. In its pure state it cannot be inhaled, because its contact with the larynx causes spasmodic contraction of the glottis; but when diluted with two or more volumes of air, it can be breathed, and produces symptoms of vertigo and somnolency; and so great a loss of muscular power, that the individual, if in an erect or sitting position, falls as if struck to the ground. The respiration, which at first is difficult and stertorous, becomes suspended. The action of the heart is at first violent, but soon ceases, sensibility is lost, and the person now falls into a comatose or death-like state. Those who have been resuscitated usually feel pain in the head and general soreness of the body for some days, and in a few severe cases, paralysis of the muscles of the face has remained. As a winter seldom passes without several deaths being recorded from coal or charcoal being employed as fuel in ill-ventilated rooms (often without any kind of chimney), it is expedient that every one should know what is to be done in such an emergency. The patient must, of course, be at once removed from the poisonous atmosphere, after which artificial respiration should be had recourse to. If the skin is warm, cold water may be poured on the head and spine; while if the surface be cold, a warm bath should be employed.

When respiration is re-established, venesection will often relieve the congestion of the vessels of the brain. The inhalation of oxygen gas is said to have been of service in these cases. *Carbonic oxide*, which exists largely in coal gas, is at least as active a poison as carbonic acid, and is doubtless the principal cause of the effects produced by the inhalation of diluted gas. Both carbonic acid and carbonic oxide act as powerful narcotic poisons. *Sulphuretted hydrogen*, which occurs abundantly in foul drains, sewers, cess-pools, &c., is a gaseous poison whose effects are often noticed. Nothing certain is known of the smallest proportion of this gas required to destroy human life; but air containing only one eight-hundredth of its volume of this gas will destroy a dog; and when the gas exists in the proportion of one two-hundred-and-fiftieth, it will kill a horse. Dr. Taylor states that the men who were engaged in the construction of the Thames Tunnel suffered severely from the presence of this gas, which was probably derived from the action of the water on the iron pyrites in the clay, and which issued in sudden bursts from the walls. By respiring this atmosphere, the strongest and most robust men were in the course of a few months reduced to an extreme state of exhaustion, and several died. The symptoms with which they were first affected were giddiness, sickness, and general debility; they became emaciated, and fell into a state of low fever accompanied by delirium. In this case the dilution was extreme; when the gas is breathed in a more concentrated form, the person speedily falls, apparently lifeless. It appears to act as a narcotic poison when concentrated; but like a narcotico-irritant when much diluted with air.

The action of the vapor of *hydrosulphate of ammonia*, which is also commonly present in cesspools, is probably much the same as that of sulphuretted hydrogen. The experiments of Dr. Herbert Barker, show, however, that these matters do not produce similar symptoms on dogs (*On Malaria and Miasmata*, p. 212).

Many of the gases, which are only found as products of the laboratory, are in the highest degree poisonous, as arseniuretted hydrogen, cacodyl, &c.; but as few persons run the risk of inspiring them, it is unnecessary to enter into any details regarding it.

We now turn to the consideration of the poisons not included in the definition, which, for want of a better, we have adopted. The poisons that may affect the body by direct introduction into the circulation, through a puncture or abrasion, may be derived from the mineral, the vegetable, or the animal kingdom; but, with a few exceptions (as, for example, Wourali Poison, q. v.), the poisons derived from the mineral and vegetable kingdoms would act as efficiently if introduced into the stomach as if injected into the circulating blood; while the animal poisons act only by direct introduction into the blood, and are inert when introduced into the stomach. Poisoned wounds derived from the dissection of recently dead bodies, commonly known as *dissecting wounds*, are occasionally attended with the most alarming symptoms, and often terminate fatally. In the case of Dr. Pett, quoted by Travers in his work *On Constitutional Irritation*, the symptoms on the third day were 'a haggard and depressed countenance; violent shiverings, followed by some degree of heat; extreme alter-

ation in appearance; countenance suffused with redness; the eyes hollow and ferrety; some difficulty of breathing, which was sudden, irregular, and amounting almost to sighing; excessive torpor, and the whole aspect resembling one who had taken an overdose of opium; on the following day there was extreme exhaustion and feebleness, and death ensued on the fifth day.' The symptoms produced by the bites and stings of insects, arachnidans, and serpents, and the treatment that should be adopted, are described in the article **VENOMOUS BITES AND STINGS**. The poisoned wounds derived from diseased animals are sufficiently discussed in the articles **GLANDERS** and **HYDROPHOBIA**.

In point of Law, the use of poison to kill or injure a human being or certain animals, renders the poisoner amenable to the criminal courts. With regard to the sale of poisons, the legislature found it necessary to put some restrictions on one description—viz., arsenic—in order to prevent persons obtaining it with facility, and in such a manner as to avoid detection. The 14 and 15 Vic. c. 13, requires every person who sells arsenic to enter in his books the date and quantity and purpose of its use, and later acts apply this rule to other poisons. It is not to be sold to one who is unknown to the vendor unless in presence of a witness who is known, and whose place of abode is recorded in the book. The arsenic must also be mixed with soot or indigo, in the proportion of $\frac{1}{2}$ oz. of soot or indigo to the lb. All the boxes, bottles, &c., must be labelled 'Poison.' Those who offend as to arsenic incur a penalty of £20; but in ordinary prescriptions, poisons may be used in the ordinary way by duly qualified medical practitioners. As to the restriction on the sale of other poisons, see **CHEMIST**. The offences committed by those who administer poisons to mankind are as follow: Whoever causes death by poison commits murder, for the means are immaterial if the death was caused by such means with a felonious intent. Where death is not caused, nevertheless whoever administers poison, or causes it to be administered to any person, with intent to commit murder is guilty of felony, and is liable to penal servitude for life, or for not less than three years. Moreover, whoever attempts to administer poison, or other destructive thing, to any person with intent to commit murder, is guilty of felony, and is punishable in the same way. These offences are committed whether the poison administered, or attempted to be administered, does injury or not; and it is a sufficient committing of the offence if the poison is put in such a place that a party was likely, and was intended to take it. Moreover, even though murder was not intended, but merely an intent to endanger life or inflict grievous bodily harm, still the offence is felony, and is punishable by penal servitude varying from three to ten years. There is also a similar punishment for the attempt to administer any stupefying drug.

Not only is it a crime to administer, or attempt to administer poison to human beings, but if cattle are maliciously killed by poison, the offence is felony, punishable by penal servitude of from three to fourteen years. So to kill by poison any dog, bird, beast, or other animal, ordinarily kept in a state of confinement, is an offence punishable by justices of the peace with imprisonment for six months, or a fine of £20 over and above the injury done. If any person lay poison on lands to kill game, he incurs a penalty of £10. And though tenants of farms, when entitled to kill the game on the estate, may kill hares without having taken out any game certificate, yet they are prohibited from killing such hares by poison. Moreover, by a recent act, 26 and 27 Vic. c. 113, extending to the United Kingdom, whoever sells, or offers to sell poisoned grain, seed, or meal, incurs a penalty of £10. Whoever sows, lays, or puts on ground such poisoned grain incurs a like penalty. The use of poisoned flesh is also prohibited. But the sale or use of solution, material, or ingredient for dressing, protecting, or preparing any grain or seed for agricultural use only, if used *bona fide*, is not interfered with.

POISSON, SIMEON-DENIS, a celebrated French geometer, was born at Pithiviers, in the dep. of Loiret, 21st June 1781; and displaying an aptitude for mathematics, he was received into the Ecole Polytechnique in 1798. The striking talent he thus early exhibited attracted the notice of Lagrange and Laplace, both of whom anticipated for him a brilliant future. In 1802, he became a professor in the Polytechnique; in 1808, a member of the Bureau des Longitudes; in 1809, Professor of Mechanics to the Faculty of Sciences; member of the Institute in 1812, &c.; and this list of distinction was crowned in 1837 by his elevation to the dignity of a peer of France. He died in 1840. P.'s whole life was devoted to the prosecution of scientific research, and the fruits of his pen number about 300 Memoirs, inserted in the publications of the Ecole Polytechnique, of the Academy of Sciences, and other scientific journals. A complete summary of these labors by P. himself is published by Arago (*Notices Biographiques*, vol. ii.). Of the separate treatises published by P., the following are the chief: *Traité de Mécanique* (2 vols. 1833); *Nouvelle Théorie de l'Action Capillaire*; *Théorie Mathématique de la Chaleur* (1835); *Mémoire sur le Mouvement des Projectiles dans l'Air, en ayant égard à la*

Rotation de la Terre (1839); and lastly the celebrated work, *Sur l'Invariabilité des Moyens Mouvements des grands Axes Planétaires*.

P. is fairly considered one of the chief founders of the science of mathematical physics, which was brought by him to great perfection, especially in what concerns statical electricity and magnetism. Many other ingenious discoveries and speculations are dispersed throughout his writings.

POITIERS, earlier *Poictiers*, a corruption of the Latin *Pictavium*, so-called by the Gallic tribe, the *Pictavi*, who inhabited the district in Cæsar's time, is one of the oldest towns in France; it is the capital of the department of Vienne, and formerly of the province of Poitou. It occupies the summit and slopes of a little eminence, round the base of which flow the Clain and the Boivre, is encircled by walls and towers, and has a very dull appearance. Pop. (1881) 35,710. It is connected by railway with Tours, from which it is 63 miles distant, and Bordeaux. Before the revolution, P. had an immense number of churches, chapels, monasteries, and nunneries; even yet these are sufficiently numerous. The principal are the church of St. Jean (now converted into a *Musée*), one of the oldest Christian monuments in France; and the cathedral of St. Pierre, one of the finest in France, belonging (in part) to the 12th c., and in which, or in the older edifice that occupied its site, 23 councils were held—the first in the 4th, and the last in the 15th century. It also contains the ashes of Richard Cœur-de-Lion. Its university, founded by Charles VII. in 1431, was also abolished after 1789, but its place has been supplied by a university-academy with two faculties. P. possesses, besides, a very celebrated lyceum, and a variety of other educational institutions, a public library of 25,000 vols. and MSS., a museum, and several learned societies, of which the most distinguished is that for the cultivation of the antiquities of Western France. In and around P. are numerous Celtic and Roman remains. In the vicinity, Alaric II., the Visigoth, was defeated and slain by Clovis in 507.

Somewhere between P. and Tours a great battle took place in 732, between the Franks under Charles Martel (q. v.) and the Moors under Abd-ur-Rahmân. The Moors were routed with enormous slaughter—375,000 of them (according to one old exaggerating chronicler) being left dead on the field; later still (in 1356), at Maupeirtuis-le-Beauvois, about 5 miles north of P., Edward the Black Prince, with some 12,000 or 14,000 Englishmen and Gascons, beat 60,000 of the troops of King Jean of France, and took the monarch himself and one of his sons prisoners.

POITOU, a former province of Western France, is now mainly comprised in the departments of Deux Sèvres, Vendée, and Vienne. It was divided into Upper and Lower P., and had for its capital Poitiers (q. v.). P. first became a possession of the English crown when Eleanor, Countess of P. and Duchess of Aquitaine, after her divorce from Louis VII. of France in September 1151, married, on Whitsunday following, Henry of Anjou, afterwards Henry I. of England. Philippe-Auguste reconquered the province in 1204, and in 1295 it was formally ceded to France. By the peace of Bretigny, in 1360, it again reverted to England, but was soon after retaken by Charles V., who gave it to his brother, the Duke of Berri. It was subsequently incorporated with the French crown.

POI'TRINAL, or **PECTORAL**, in ancient armor, was the horse's breastplate, formed of metal plates riveted together as a covering for the breast and shoulders.

POKHU'RN, a town of India, in the Rajpoot state of Jodhpoor; 340 miles south-west of Delhi. It is situated close to a deserted town of the same name, the site of which is marked by a very conspicuous temple in an elevated situation. P. has a considerable trade and a pop. of about 15,000.

PO'LA, the most important naval station of Austria, and one of the most beautiful havens in Europe, belongs to the Markgrate of Istria. The town occupies an eminence overlooking the Adriatic Sea, 75 miles by sea south of Trieste. The bay is thoroughly sheltered, and is spacious enough to accommodate the largest fleet. The town is surrounded by bastioned walls, is protected by numerous batteries, and is overlooked by the citadel by which it and the bay are commanded. Pop. (1880) 25,173.

P., a very ancient town, is said to have been founded by the Colchians, who were sent in pursuit of Jason. It was destroyed by Julius Cæsar, but rebuilt by Augustus at the request of his daughter Julia, on which account it was named *Pietas Julia*. In ancient times it had 30,000 inhabitants, and was a station of the Roman fleet. It contains numerous and interesting Roman remains, among which are a beautiful and well-preserved amphitheater, 436 feet long, and 346 broad. A temple and several ancient gates are also extant. See Allason's *Antiquities of Pola* (Lond. 1819).

POLA'CCA, or **POLONAI'SE**, a Polish national dance of slow movement in $\frac{3}{4}$ time. It always begins and terminates with a full bar, and a peculiar effect is produced by the position of its

eadence, the dominant seventh in the second crotchet of the bar preceding the triad on the third crotchet:

The characteristic features of the

polacca are sometimes adopted in a Rondo, or other lively and brilliant composition which is then said to be written *Alla Polacca*.

POLACCA, or POLACRE, a species of vessel in use in the Mediterranean, with three masts and a jib-boom; the fore and main-masts being of one piece ('pole-masts'), and the mizen-mast with a top and top-mast. They generally carry square sails, though a few are rigged with a peculiar form of sail to which the term *polacre* is also applied. The fore and main-masts have, of course, neither tops, caps, nor cross-trees.

PO'LAND, called by the natives *Polska* (a plain), a former kingdom of Europe—renowned in medieval history, as the sole champion of Christendom against the Turks; and till recently, an object of general and profound sympathy throughout Western Europe, from its unprecedented misfortunes—was, immediately previous to its dismemberment, bounded on the N. by the Baltic Sea from Danzig to Riga, and by the Russian provinces of Riga and Pskov; on the E. by the Russian provinces of Suolensk, Tchernigov, Poltava, and Kherson; on the S, by Bessarabia, Moldavia, and the Carpathian Mountains; and on the W. by the Prussian provinces of Silesia, Brandenburg, and Pomerania. Its greatest length from north to south was 713 English miles; and from east to west, 693 miles, embracing an area of about 282,000 English square miles; an area which, in 1880, had a population of 24,000,000. This extensive tract forms part of the great central European plain, and is crossed by only one range of hills, which springs from the north side of the Carpathians, and runs north-east through the country, forming the water-shed between the Baltic and Black Sea rivers. The soil is mostly a light fertile loam, well adapted for the cereal crops, though here and there occur extensive barren tracts of sand, heath, and swamp, especially in the eastern districts. Much of the fertile land is permanent pasture, which is of the richest quality; and much is occupied with extensive forests of pine, birch, oak, &c. Rye, wheat, barley, and other cereals, hemp, wood, and its products, honey and wax, cattle, sheep, and horses, inexhaustible mines of salt, and a little silver, iron, copper, and lead, constitute the chief natural riches of the country; and for the export of the surpluses of these products, the Vistula, Dnieper, Duna, and their tributaries afford extraordinary facilities.

The kingdom of P., during the period of its greatest extent, after the accession of the grand-duchy of Lithuania in the beginning of the 15th c., was subdivided for purposes of government into about 40 palatinates or voivodes, which were mostly governed by hereditary chiefs. The people were divided into two great classes—nobles and serfs. The noble class, which was the governing and privileged class, included the higher nobles, the inferior nobles (a numerous class, corresponding to the knights, gentry, &c., of other countries), and the clergy, and numbered in all more than 200,000; the serfs were the merchants, tradesmen, and agriculturists, and were attached, not, as in other countries, to masters, but to the soil. The serfs were thus much less liable to ill-usage, and retained more of human energy and dignity than the generality of slaves. The nobles were the proprietors of the soil, and appropriated the larger portion of its products, the serfs in many cases receiving only as much as was necessary for the support of themselves and their families. The nobles were chivalrous, high-spirited, hospitable, and patriotic; the serfs, who had also a stake, though a small one, in the independence of the country, were patriotic and good-natured, but sluggish. The present population of the provinces included in the P. of former days, consists of Poles, Lithuanians, Germans, Jews, Russians, Rumanians, gipsies, &c. The Poles, who number 15,600,000, form the bulk of the population; the Lithuanians, 2,100,000 in number, inhabit the north-east of the country; the Germans, of whom there are 2,000,000, live mostly in towns and in villages apart by themselves, and bear the usual character for economy, industry, and that excessive love and admiration for the 'Fatherland,' which guided their politics during the last days of Polish independence; the Jews are very numerous, being reckoned at 2,200,000, but here they are poorer and less enterprising than in other countries; the remainder is composed of Russians (who are few in number, excepting in some of the eastern districts), Russian soldiery, Rumanians, gipsies, Magyars, &c. Of Roman Catholics, there are about 9,400,000; Greeks, United and Non-united, 7,900,000; Protestants (mostly Lutherans, and Germans), 2,360,000; the rest are Jews, Armenians, Moslems, &c.

History.—The Poles are ethnologically a branch of the Slaves

(q. v.). The name appears first in history as the designation of a tribe, the Polani, who dwelt between the Oder and Vistula, surrounded by the kindred tribes of the Masovii, Kujavii, Chirobates, Silesians, Obotrites, and others. In course of time, the Polani acquired an ascendancy over the other tribes, most of whom became amalgamated with the ruling race, whose name thus became the general designation. Polish historians profess to go as far back as the 4th c.; but the lists of rulers which they give are probably those of separate tribes, and not of the combined race now known as Poles. At any rate, the history of P., previous to the middle of the 9th c., is so largely adulterated with fables, as to be little trustworthy. Ziemowicz, said to be the second monarch of the Piast dynasty, is considered to be the first ruler whose history is to any extent to be relied upon; and it was not till a century after, when his descendant, Mielcislas I. 962–992, occupied the throne and became a convert to Christianity, that P. took rank as one of the political powers of Europe. Mielcislas (as was the general custom among the Polish rulers) divided his dominions among his sons; but one of them, Boleslas I. (992–1025), surnamed 'the Great,' soon re-united the separate portions, and extended his kingdom beyond the Oder, the Carpathians, and the Dniester, and sustained a successful war with the Emperor Henry II. of Germany, conquering Cracovia, Moravia, Lusatia, and Misnia. He also took part in the dissensions among the petty Russian princes. Under him, P. began to assume unity and consistency; commerce, the impartial administration of justice, and Christianity, were encouraged and promoted; and about the same time, the distinction between the nobles or warrior class (those who were able to equip a horse) and the agriculturists was distinctly drawn.

Boleslas was recognized as 'king' by the German emperors. After a period of anarchy, he was succeeded by his son, Casimir (1040–1058), whose reign, and that of his warlike son, Boleslas II. (1058–1081), though brilliant, were of little real profit to the country. The latter monarch having with his own hands murdered the Bishop of Cracow (1079), P. was laid under the papal interdict, and the people absolved from their allegiance; Boleslas accordingly fled to Hungary, but being, by order of the pope, refused shelter, he is said to have committed suicide (1081). Boleslas III. (1102–1139), an energetic monarch, annexed Pomerania, defeated the pagan Prussians, and defended Silesia against the German emperors. A division of the kingdom among his sons was productive of much internal dissension, under cover of which, Silesia was severed from P., though still nominally subject to it. Ultimately, Casimir II. (1177–1194) re-united the severed portions, with the exception of Silesia, and established on a firm footing the constitution of the country. A senate was formed from the bishops, palatines, and castellans, and the rights of the clergy and of the peasantry were accurately defined. His death was the signal for a contest among the various claimants for the throne, which was speedily followed, as usual, by a division of the country, and during this disturbance Pomerania emancipated itself from Polish rule. About the same time, the Teutonic Knights were summoned by the Duke of Masovia to aid him against the pagan Prussians; but they soon became as formidable enemies to P. as the Prussians, and conquered great part of Podlachia and Lithuania. The Mongols swept over the country in 1241, reducing it to the verge of ruin, and defeating the Poles in a great battle near Wahlstatt. From this time, P. began to decline; various districts were ceded to the margraves of Brandenburg, while many districts began to be colonized by Germans. Numbers of Jews, persecuted in Western Europe about this time, took refuge in Poland.

Wladislas (1305–1333), surnamed *Lokietek* (the Short), again restored unity to the country, judicial abuses and all illegally acquired privileges were abolished, and the first diet (1381) assembled for legislative purposes. In conjunction with Gedymin, Grand Duke of Lithuania, a vigorous war was carried on against the Teutonic Knights, on returning from which the aged monarch (he was now 70 years old) experienced a triumphant reception from his subjects, who hailed him as the 'father of his country.' His son, Casimir III. the Great (1333–1370), greatly increased the power and prosperity of P. by cultivating with zeal the arts of peace, amending the laws, and consolidating his territories by profitable exchanges with the neighboring powers. In the latter part of his reign, he was compelled to defend sundry new acquisitions against the Tartars, Lithuanians, and Wallachians, which he did successfully. With Casimir, the Piast dynasty became extinct, after a sway of 510 years, according to the old Polish chroniclers. His nephew, Lewis the Great, king of Hungary, succeeded him, by the will of the deceased monarch and the election of the diet; but during his reign, P. was treated merely as an appanage of Hungary. On his death without male heirs, the crown fell to Jagello (Wladislas II.), Grand Duke of Lithuania, the son-in-law of Lewis, who founded the dynasty of the *Jagellons* (q. v.) (1386–1572), and for the first time united Lithuania and P., thus doubling the extent, though not the pop-

ulation of the kingdom. However, his successor Wladislas III., was acknowledged only in P. proper, the Lithuanians preferring the rule of the younger son, Casimir. Wladislas was also chosen king of Hungary, and fell at the battle of Varna, being succeeded in P. by Casimir IV. (1444—1492), who again united it to Lithuania. Casimir recovered West Prussia from the Teutonic Knights, and compelled them to do homage to East Prussia, rewarding the inferior nobles, or warrior class, with more extensive privileges, putting them on an equality of rank with the great chiefs of the realm, and at the same time necessarily oppressing the peasantry.

Manufactures and commerce revived to a wonderful extent during his reign in the western provinces. The brief reigns of his three sons were marked only by the increased power of the two houses of the diet, which had by this time absorbed all but the symbols of supreme authority, and had converted P. from a monarchy to an oligarchy (the king possessing little power beyond what his personal influence gave him). Sigismund I. (1506—1548) surnamed the Great, the fourth son of Casimir, raised the country to the utmost pitch of prosperity. Generous and enlightened, he was beloved by the masses, whom he endeavored to benefit physically and mentally, while his firmness and justice commanded the respect of the turbulent nobles. He wisely kept aloof from the religious quarrels which distracted Western Europe, by allowing his subjects perfect freedom of choice in matters of religion; he was, however, forced into a war with Russia, in which he lost Smolensk; but he was partly compensated by obtaining lordship over Moldavia. His son, Sigismund II., Augustus, was a successor worthy of him. During his reign many abuses were rectified, and the extraordinary privileges of the higher nobles were curtailed or abolished; Lithuania was finally joined indissolubly to P., and from this time there was to be but one diet for the united realm; each retained, however, its own army, titles, treasury, and laws. Lithuania was at the same time reduced by the annexation of Podlachia, Volhynia, and the Ukraine, to Poland. Livonia was conquered from the Knights Sword-bearers (a community similar to, though much less distinguished than the Teutonic Knights); and the power, prosperity, and opulence of the state seemed to guarantee its position as the most powerful state in Eastern Europe for a long time to come. The population almost doubled itself under the two Sigismunds; but this dynasty, whose sway was so happy for P., ceased with them; and the warrior class having tasted the sweets of freedom, determined to preserve it by rendering the monarchy elective.

The election was made by the two chambers of the diet—viz., the senate or chamber of the chief nobles, and the chamber of nuncios, or representatives of the inferior nobles. He who was chosen king possessed the right of assembling the diet, but had to give a list of the subjects to be discussed; and the representatives, before setting out, were instructed as to the side they were to support. The diet only lasted six weeks, and its decisions were required to be unanimous; so that if the *liberum veto* (the right of forbidding the passing of any measure) were freely exercised even by a single member, all legislation was at a stand-still. The evil effects of these regulations were not so much felt at first, as the members were characterized by honesty and zeal for the general good; but latterly, when venality and subservience to the neighboring powers began to show themselves, all the measures necessary for protecting P. from dependence on her neighbors were, by a few corrupt and treacherous representatives, rendered of no avail. The first elective monarch was Henry of Valois (III. of France, q. v.), who, however, soon abandoned the throne for that of France, and was succeeded by Stephen Bathory (1575—1586), voivode of Transylvania, a man of energy and talent, who carried on war successfully against the Russians, who had attempted to seize Livonia, pursued them into the very heart of their own country, and compelled the czar to sue for peace; he also subdued the semi-independent Cossacks of the Ukraine, and to some degree introduced civilization among them. His successor, Sigismund III. (1586—1632), who was succeeded by his sons, Wladislas IV. (1632—1645) and John Casimir (1648—1672), was of the Vasa family, and was the crown-prince of Sweden; but his election, far from cementing a bond of union between the two countries, only embittered former dissensions.

These three Swedish monarchs were most unworthy successors to P.'s ablest king, as they had neither talents for governing nor characters and sentiments congenial to a warlike nation; on the contrary, their policy was weak, tortuous, and vacillating. Yet they were always quarrelling with their neighbors, declaring war with Russia, Sweden, or Turkey, in the most imprudent and reckless manner, and often without valid pretext. But the Polish armies, though as little fostered and cared for as the other portions of the nation, were everywhere victorious; the Swedish and Muscovite armies were successively annihilated; Moscow was taken, and the Russians reduced to such an abject condition, that they offered to make Sigismund's son, Wladislas, their czar. Sweden made a similar offer to another son of the Polish monarch;

but the latter's absurd behavior lost for P. this rich result of her great victories; and the foolish policy of the whole three not only rendered fruitless all the lavish expenditure of Polish blood and treasure, but lost to the country many of her richest provinces, and left her without a single ally; while their religious bigotry commenced that reign of intolerance and mutual persecution between the various sects which was the immediate cause of P.'s downfall. To show the power of the Poles at this period, it will be sufficient to notice that Great P., Little P. (Galicia, Podolia, Ukraine, &c.), Livonia, Lithuania (including Samogitia and Black and White Russia, Polesia, and Tchernigov), Pomerelia and Ermeland, Courland, Moldavia, Bukovina, Walachia, Bessarabia, and Prussia, were either integral parts of the Polish monarchy, or were subject to it. The imprudent attempt of the Swedish sovereigns to amend the constitution only excited the suspicion of the nobles, and led to a further curtailment of royal authority. During the reign of this dynasty, Walachia and Moldavia were snatched by the Turks from under the Polish protectorate; Livonia with Riga was conquered (1605—1621), along with part of Prussia (1629), by Sweden; and Brandenburg established itself in complete independence.

The Cossacks, who had been goaded almost to madness by the atrocious oppression and religious persecution, rose in rebellion to a man, put themselves under the protection of Russia, and ever afterwards proved themselves the most inveterate enemies of the Poles. In the reign of John Casimir, P. was attacked simultaneously by Russia, Sweden, Brandenburg (the germ of the present kingdom of Prussia), the Transylvanians, and the Cossacks; the country was entirely overrun; Warsaw, Wilna, and Lemberg taken; and the king compelled to flee to Silesia. But the celebrated staff of Polish generals was not yet extinct; Czarniecki's sword was as the breath of the destroying angel to P.'s enemies; and after being defeated in detail, they were ignominiously expelled from the country. But in the subsequent treaties, Dnial or East Prussia was wholly given up to Brandenburg; almost all Livonia to Sweden; and Smolensk, Severia or Tchernigov, and the Ukraine beyond the Dnieper, were given to Russia. Michael Wisniowiecki (1668—1674), the son of one of the group of famous generals above alluded to, but himself an imbecile, was (contrary to his own wish—for he was well aware of his own deficiencies) elected as their next monarch; a war with Turkey, concluded by an ignominious peace, was the chief event of his reign. But the senate rejected the shameful treaty, the Polish army was again reinforced, the Polish monarch resigned the command to John Sobieski the Hetman (q. v.), and the Turks were routed with great slaughter at Choczim (1673). After some dissensions concerning the election of a successor, John (III., q. v.) Sobieski (1674—1696) was chosen; but his reign, though it crowned the Poles with abundance of the laurel wreaths of victory, was productive of no good to the internal administration. As Sobieski's successor, the Prince of Conti was legally elected, and proclaimed king; but the cabinet of Versailles allowed this splendid opportunity of becoming supreme in Europe to escape; and Augustus II. of Saxony, a protégé of the House of Austria, entered P. at the head of a Saxon army, and succeeded in obtaining the throne.

Augustus, unlike all his predecessors, never seemed to identify his interests with those of his Polish subjects; and though he gained their hearts by promising to reconquer for P. her lost provinces, yet this promise was chiefly made as an excuse for keeping his Saxon army in the country, in violation of the *pacta conventa* (the 'Magna Charta' of Poland). His war with the Turks restored to P. part of the Ukraine and the fortress of Kaminniec; but that with Charles XII. brought nothing but misfortune. The war with Sweden was unpopular in P.; in fact, the Poles of the eastern provinces received Charles with open arms; but his attempt to force upon them Stanislas Leszczynski as their king severely wounded their national pride. Augustus returned after the battle of Poltava (q. v.); his rival retired without a contest; a close alliance was formed with Russia, and the Russian troops which had campaigned in P. against the Swedes were, along with the Saxon army, retained. The Poles demanded their extradition, but in vain; and the Russian cabinet interfered (1717) between the king and his subjects, compelling both parties to sign a treaty of peace. This was the commencement of P.'s dependence on Russia, and her consequent decline. By the instigation of Peter the Great, the Polish army was reduced from 80,000 to 18,000; and the country was further weakened by the diffusion of effeminacy, immorality, and prodigality, through the evil example and influence of the court. Religious fanaticism also more fully developed its most odious features during his reign, and the massacre of the Protestants at Thorn (1724) and the legalized exclusion of them from all public offices was the result. The succeeding reign of Augustus III. (1733—1763) was of the same character; the government fell more and more under Russian influence, and its political relations with other countries gradually ceased. Towards the end of his reign, the more enlightened of the Poles, seeing the radical defects of the constitution, the want of a strong

central government, and the dangers of the *liberum veto*, entered into a league to promote the establishment of a well-organized hereditary monarchy. But the conservative or republican party was equally strong, and relied on Russian influence; and the conflict between these parties became more embittered from the fact, that the monarchists supported the Jesuits in disqualifying all dissenters from holding public offices, while the republican party supported the dissidents.

The dissidents dated their grievances from 1717, but the great conflict between them and their opponents did not break out till 1763. The cabinets of St. Petersburg and Berlin now (1764) presented to the Poles Stanislas Poniatowski as their king. This gross insult, intensified by the incapacity of Stanislas for such an office, could not be borne in quiet; the king and the Russian ambassador were compelled in the diet to listen to the most spirited protests against Russian interference; but the intense national spirit of the Poles only recoiled upon themselves, for the Russian ambassador craftily incited them to insurrection, and kept alive their mutual dissensions. The monarchic, of Czartoryski party (so called because it was headed by a Lithuanian prince of this name) had succeeded in abolishing the *liberum veto*, and effecting many other improvements; but they at the same time more severely oppressed the dissidents; and Russia, finding that the political policy of this party was speedily releasing P. from her grasp, joined the party of the dissidents as the champion of religious toleration! Her ambassador caused the chief leaders of the Catholic party to be secretly kidnapped, and sent to Siberia, and compelled the republicans to accept the protectorate of Russia. The 'Confederation of Bar' (so called from Bar in Podolia) was now formed by a few zealous patriots, an army was assembled, and war declared against Russia. The confederates were supported by Turkey, which also declared war against the czarina; and Russia, alarmed at the appearance of affairs, proposed to the king and diet an alliance, which both firmly refused. Frederic the Great of Prussia, who had formerly gained the consent of Austria to a partition of P., now, in 1770, made the same proposal to Russia, and in 1772, the first partition was effected; Stanislas and his diet claiming the mediation and assistance of the other powers of Europe without effect. He was forced in the following year to convoke a diet for the purpose of recognizing the claims of the three partitioning powers to the territories they had seized, but few members appeared, and these preserved perfect silence.

The territories seized by the three powers were as follows:

	Eng. sq. Miles.	Pop.
Russia	42,000	1,800,000
Prussia.....	13,000	416,000
Austria.....	27,000	2,700,000

The whole country was now aroused to a full sense of its danger; and the diet of the diminished kingdom labored to amend the constitution and strengthen the administration by a liberal code of laws and regulations, which gave political rights to the cities, civil rights to the peasantry, and rendered the kingly authority hereditary. In this they were encouraged by Prussia, whose king, Frederick William, swore to defend them against Russia; but in 1791, Catharine II., after great labor, obtained, by means of intrigues and bribery, the services of *fines* (out of 200,000) of the Polish nobility, who protested against the new constitution which had just (May 3, 1791) been established, and drew up a document at Targowitz (q. v.), which they forwarded to the Russian court. Catharine, thus armed with a pretext for interference, advanced her army, and Prussia proving traitorous, a second fruitless resistance to the united Prussians and Russians, headed by Joseph Poniatowski (q. v.) and Kosciusko (q. v.), was followed by a second partition (1793) between Russia and Prussia, as follows:

	Eng. sq. Miles.	Pop.
Russia.....	96,000	3,000,000
Prussia.....	22,000	1,100,000

which the diet were forced to sanction at the point of the bayonet. The Poles now became desperate; a general rising took place (1794); the Prussians were compelled to retreat to their own country, and the Russians several times routed; but then a new enemy appeared on the scene. Austria was chagrined at having taken no part in the second partition, and was determined not to be behindhand on this occasion; her army accordingly advanced, compelling the Poles to retreat; and fresh hordes of Russians arriving, Kosciusko, at the head of the last patriot army, was defeated; and the sack of Praga, followed by the capture of Warsaw, finally annihilated the Polish monarchy.

The third and last partition (1795) distributed the remainder of the country as follows:

	Eng. sq. Miles.	Pop.
Russia.....	43,000	1,200,000
Prussia.....	21,000	1,000,000
Austria.....	18,000	1,000,000

King Stanislas resigned his crown, and died broken-hearted at St. Petersburg in 1798. The subsequent success of the French against the Russians, and the tempting promises of the Emperor Napoleon to reconstitute P., rallied round him a faithful army of patriots, who distinguished themselves in the campaigns of the French against Russia and Austria; but all that Napoleon accomplished in fulfilment of his promise was the establishment, by the treaty of Tilsit (1807), of the *Duchy of Warsaw*, chiefly out of the Prussian share of P., with a liberal constitution, and the Elector of Saxony at its head. The duchy was an energetic little state, and under the guidance of Prince Joseph Poniatowski, wrenched Western Galicia from Austria (1809), at the same time furnishing a numerous and much-valued contingent to the French armies; but the advance of the grand allied army in 1813 put an end to its existence. After the cessions by Austria in 1809, the duchy contained 58,290 English square miles, with a population of about 4,000,000. Danzig was also declared a republic, but returned to Prussia (February 3, 1814).

The division of P. was re-arranged by the Congress of Vienna in 1815, the original shares of Prussia and Austria were diminished, and that part of the duchy of Warsaw, which was not restored to Prussia and Austria, was united as the *kingdom of P.* (see next article) to the Russian empire, but merely by the bond of a personal union (the same monarch being the sovereign of each), the two states being wholly independent of and unconnected with each other; and the other parts of P. were completely incorporated with the kingdoms which had seized them. The partition of P., as thus finally arranged, was as follows:

Extent in Eng. sq. Miles.	Pop. [in 1855].	Present Political Divisions.
Russia.... 220,500	16,000,000	Provinces of Courland, Witbesk, Kovno, Vilna, Grodno, Minsk, Mohilev, Volhynia, Kiev, Po-
Prussia.... 26,000	3,000,000	Poland, and the Kingdom of Poland (q. v.).
Austria.... 35,500	5,000,000	Posen, most of W. Prussia, and several districts in E. Prussia, Galicia, Bukovina, Zips, &c.

while, as if in mockery of its spirit of independence, the town of Cracow, with a small surrounding territory, was declared free and independent, under the guardianship of Austria. The czar at first gave a liberal constitution, including biennial diets, a responsible ministry, an independent judiciary, a separate standing army, and liberty of the press; and he seemed to take pride in his title of king of P.; but his brother Constantine, having been appointed military governor, speedily put an end to the harmony between the czar and the Poles, and drove the latter into insurrection. Their discontent at first found vent in secret societies; but on November 30, 1830, Constantine and his Russians were driven out of Warsaw, and a general insurrection of the people, headed by the aristocracy, took place. Prince Czartoryski was appointed president of the provisional government, and military leaders, as Radzivil, Dembinski, Bem, &c., were soon found; but a general want of energy in the administration, dilatoriness on the part of the military leaders, and the checking of the spread of the insurrection till fruitless negotiations had been entered into with Nicholas, were errors fatal to the success of the Poles.

From January 1831 till September 8th of the same year, a series of bloody conflicts were fought, in which the Prussians and Austrians, with pitiable subservience, aided the czar. At first, the Poles were successful; but the taking of the capital by Paskevitch (q. v.) soon ended the war, which was followed, as a matter of course, by imprisonment, banishment, confiscation, and enforced service in the Russian army. From this time, the independence of P. was suppressed, and in 1832 it was declared to be an integral part of the Russian empire, with a separate administration headed by a viceroy of the czar's choosing; the constitution and laws were abrogated; strict censorship of the press and the Russian spy police-system established in all its vigor; the country was robbed of its rich literary collections and works of art; and the most severe and arbitrary measures taken to Russianize the people.

The outbreaks of 1833 and 1846 were punished by the gallows. Simultaneous disturbances (1846) in the Prussian and Austrian portions of P. were summarily suppressed; their leaders in Prussia were imprisoned, and only saved from death by the revolution of March 1848 at Berlin; and those in Austria were butchered by the peasantry, who preferred the Austrian to a national government. On the 6th of November 1846 the republic of Cracow was incorporated with Austria. After the accession of the Czar Alexander II. in 1855, the condition of the Poles was considerably ameliorated; an act of amnesty brought back many of the expatriated Poles, and various other reforms were hoped for, when, in 1861, another insurrection broke out. Its origin is curious, and gives a thorough insight into the relations between the Poles and their Russian rulers.

A large multitude (30,000) had assembled in the neighborhood of the battle-field of Grochow (where two battles had been fought

in the spring of 1831), to pray for the souls of those who had fallen; they were engaged in prayer and in singing religious chants, when they were charged by the Russian cavalry and gens d'armes, several of them killed, and numerous arrests made. This event excited intense national feeling throughout the country, and other national demonstrations, attended with similar massacres on the part of the Russians, produced such an intense dislike to the latter, that most of the Poles in the Russian service either resigned or deserted. The Russians immediately had recourse to the most severely repressive measures, forbidding all assemblages even in the churches, punishing those who appeared to mourn the death of relatives killed in the previous massacres, or who wore garments of certain shapes or colors. The application of the Polish nation to the czar (February 28) for the re-establishment of the Polish nationality, was rejected, but certain necessary reforms were promised. These reforms were on the whole very liberal, and tended greatly to allay the general excitement; but the Russian government was very naturally not trusted by the Poles, and new disturbances broke out in October of the same year. P. was then declared in a state of siege, and General Luders appointed military commandant under the Grand Duke Constantine, the nephew of the Grand Duke Constantine above mentioned. The country continued in a state of commotion without any very decided outbreak; attempts were made to assassinate the Grand Duke and the other Russian officials; and on January 13, 1863, Lithuania and Volhynia were also put in a state of siege.

The Committee of the National Insurrection issued its first proclamation in February 1863; and a week afterwards, Mickolski raised the standard of insurrection in the north-west, on the Posen frontier. The Insurrection Committee continued to guide the revolt by issuing proclamations from time to time; and many districts of Augustovo, Radom, Lublin, Volhynia, and Lithuania, were speedily in insurrection. It was a mere guerrilla war, and no great or decisive conflicts took place; but the sympathy of Europe was largely enlisted on behalf of the Poles. Remonstrances from Spain, Sweden, Austria, France, and Britain conjointly and repeatedly, Italy, the Low Countries, Denmark, and Portugal, were wholly disregarded by the czar's ministers, and mutual reprisals continued; incendiaryism and murder reigned rampant; the wealthier Poles were ruined by fines and confiscations; and the whole populations of villages were put to the sword by the Russians; while murders and assassinations marked the reign of terror of the National Committee. At last, with the officious assistance of Prussia, and the secret sympathy and support of Austria, the czar's troops succeeded in tramping out (1864) the last embers of insurrection. Great numbers of men, women, and even children, concerned in, or supposed to have favored the revolt, were executed; crowds were transported to Siberia; and these vigorous measures seem to have restored 'tranquillity, but it is the tranquillity of the desert.' Contemporary with this last outbreak, symptoms of similar disaffection were distinctly noticeable in Prussian P., but a strong force of soldiery in the border districts towards Russia, prevented any outbreak. It deserves to be noticed, that with the exception of the single revolt of 1846 (which perished almost of itself), no rebellion has ever taken place in the portion of P. belonging to Austria.

POLAND, KINGDOM OF, a province of European Russia, which was united to that empire in 1815—though the title of kingdom was left, and a peculiar form of government long continued to distinguish it from the other provinces—is surrounded by Prussia, Austria, and Western Russia or Russian Poland, and contains 48,863 English square miles, with a population (1880) of 7,104,760. In 1867, there were 4,326,473 Roman Catholics, 783,079 Jews, 331,237 Protestants (Lutherans and Reformed), and 259,192 Greek Church (mostly united). The surface of the country is in general very level, with now and then a hill, or rather undulation, which relieves the uniformity of the scene. In Radom, however, there is a range of hills, some peaks of which attain a height of 2000 feet above sea-level. The chief river of P. is the Vistula, which enters the country by its southern boundary, and flows first north and then north-west, making its exit near Thorne; two of its tributaries, the Wieprz and the Pillica, belong wholly, and a third, the Bug, partially to Poland. The Warta, one of the tributaries of the Oder, drains the west, and the Niemen, the north-east districts. The Vistula and the Niemen are wholly navigable in P.; and the Bug, Narew, and Warta are so for a considerable portion of their course. By these means of communication, the exports of the country are collected at Danzig, Stettin, Memel, and Tilsit, on the Baltic, and the imports introduced into the country. The climate is severe, the summers being very hot, and the winters excessively cold. The soil very much resembles that of the other parts of the former kingdom of Poland, producing magnificent crops of wheat, rye, barley, oats, and buckwheat, the usual leguminous plants, hemp, tobacco, flax, and orchard-fruits. Up-

wards of 13,000 square miles are covered with forests, and fully 8000 square miles are waste.

Since 1867, Poland is divided for administrative purposes into 10 governments—viz.:

Governments.	Eng. sq. Miles.	Pop. in 1873.
Kalisch.....	4197	687,371
Kielce.....	3621	536,146
Lomza.....	4400	495,105
Lublin.....	6260	734,018
Piotrkov.....	4484	682,495
Plock.....	3995	490,143
Radom.....	4755	546,945
Siedlce.....	5295	550,108
Ssuwalki.....	4650	542,750
Warsaw.....	5433	1,090,973
Total.....	47,090	6,356,049

The population is about 128 to the square mile, being more than three times as dense as that of the rest of European Russia. A large proportion of the country population employ themselves in the rearing and breeding of horses, cattle, and pigs; sheep are not so common; but swarms of bees abound, and there is a large export trade in honey. The population of the town is largely employed in wool-spinning and the manufacture of woollen cloth, cotton and linen spinning and weaving, the production of liqueurs, oil, vinegar, glass and earthenware, paper, beer and porter, &c. The most of the commerce is in the hands of the Jews. P., which had a separate government till 1864, was in that year deprived of the last remnant of its administrative independence. After the suppression of the revolt (see preceding article), the country was placed under eight military governors; in 1867, the administration was committed to a commission sitting at St. Petersburg; and by an ukase, dated February 23, 1868, the government of P. was absolutely incorporated with that of Russia. The total value of Polish industries in 1873 was £12,000,000, a very large sum, considering that the population is chiefly agricultural. In the same year the commerce of P. reached £25,683,874. The Warsaw daily press has an issue of 24,000 copies; and there are 31 scientific and literary periodicals. Besides, newspapers are published in the other principal towns.

POLAR CIRCLE, or ARCTIC CIRCLE. See ARCTIC.

POLAR EXPEDITIONS. Under this head are classed all those voyages of discovery which have been made towards the north and south poles, and to the regions within the Arctic and Antarctic Circles. The north polar regions present a much greater land-surface than those around the south pole, and on this account possess a higher temperature, and offer a more valuable field for discovery, for which reasons, as well as by reason of their greater proximity, polar expeditions have been far more frequently directed to the north than to the south.

Arctic Expeditions.—Polar expeditions were commenced with a view to discover a shorter route to the golden realms of the East; but the first attempts were made by coasting along the north of Europe and America. See NORTH-EAST AND NORTH-WEST PASSAGES. It was not till 1603 that the first arctic exploring expedition, consisting of one vessel, the *Godspeed*, commanded by Stephen Bennett, started for a voyage of northern discovery; and this, as well as the succeeding expeditions of Bennett, were devoted to morse-hunting rather than to geographical investigation. In 1607, Henry Hudson (q. v.) was sent out by the Muscovy Company to penetrate to the north pole, but he was stopped about the north of Spitzbergen (in lat. 81° 30') by the ice. The succeeding voyages of Jonas Poole in 1610, 1611, and 1612, and of Baffin in 1613, were not primarily voyages of discovery, and they added nothing to the previous knowledge of the polar regions; but in the expedition of Fotherby and Baffin up Davis' Strait, in the following year, the latter discovered a northern outlet to the bay called by his own name, which was denominated Smith's Sound. Fotherby was sent out again in 1615, and attempted to pass through the sea which lies between Greenland and Spitzbergen, but was again baffled, and compelled to return, after correcting some erroneous observations of Hudson. These seven expeditions were all sent out by the Muscovy Company; and the cargoes of seal-skins, oil, teeth, &c., which they brought back helped to defray the expense of their outfit.

For the next century and a half, the attempts to reach the north pole were not resumed; but the extraordinary zeal in the cause of naval discovery which sprung up in the beginning of George III.'s reign, produced two renewed efforts. The first of these was made in the spring of 1773 by an expedition, consisting of two vessels, under Captain John Phipps (afterwards Lord Mulgrave), and fitted out by the Admiralty purely for scientific purposes. Phipps sailed along the shore of Spitzbergen till he was stopped

by the ice at Cloven Cliff; he then coasted backwards and forwards along the ice-field for nearly a month, trying the various narrow openings, some of which were two leagues in depth, till he found one which took him into open water. By a sudden change in the climate, he was frozen in, and only extricated his ships after severe labor. The highest point to which he reached was lat. $80^{\circ} 48' N.$, less by 49 miles than the most northerly latitude attained by Hudson; and though he had a more than usual amount of difficulties to encounter, yet his failure, along with that of Captain Cook, who attempted to reach the pole by Behring's Strait, but only penetrated to lat. $70^{\circ} 45' N.$, greatly disheartened other explorers. The offer of £5000 by the British parliament to the crew that should penetrate to within 1° of the pole, awaked no competition; but in 1806, Mr. Scoresby, then mate of a Greenland whaler from Hull, reach a point directly north of Spitzbergen, in lat. $81^{\circ} 30' N.$, and therefore only about 510 geographical miles from the pole. In following expeditions, the same enterprising navigator made many geographical explorations of Jan Mayen's land and the east coast of Greenland, largely adding to our knowledge of the character and products of the arctic regions.

The subsequent expeditions of Buchan and Franklin in 1818, of Clavering in 1823, of Graab (Danish) in 1828, of De Blosseville (French) in 1833, may be considered as failures, as far as geographical discovery is concerned; for, omitting the French expedition, the fate of which is still involved in mystery, none of them reached so high latitudes as the previous English expeditions. After the failure of Buchan and Franklin's expedition, the impossibility of ever reaching the pole was generally accepted in this country as fact; but Mr. Scoresby, in a Memoir which he communicated to the Wernerian Society, endeavored to prove that this supposed impossibility was by no means such; in fact, that a journey to the pole could be made without any enormous amount either of difficulty or danger. The principal obstacle to be encountered being the alternation of ice-fields and water, which prevented all advance either by ships or sledges, Mr. Scoresby proposed the use of a vehicle which could be used either as a sledge or boat, and recommended a team of dogs to draw it, they being lighter (for conveyance by water, and for traveling over thin ice) and more tractable than reindeer. After some time, this suggestion began to receive a considerable share of attention, and Captain Parry (celebrated for his discoveries in the polar seas north of America) was put in command of an expedition fitted out in accordance with Scoresby's plans. He sailed from England in the *Hecla*, on March 27, 1827; but it was the 22d of June before the exploring party quitted the ship, which was left on the north shore of Spitzbergen, in charge of a small crew, and betook themselves to the boats; and in spite of the advanced season of the year, they in the first two days advanced to $81^{\circ} 13'$. Here they began to encounter many difficulties; the ice-fields were small, and near each other, necessitating a constant conversion of the vehicle from a sledge to a boat, which could not be effected without unloading it, an operation which consumed much time.

This hardship, however, was endurable; but, to Parry's intense chagrin, he discovered, about the 22d of July, that the ice over which they were traveling was moving southward as rapidly as they were advancing north, so that on the 24th, after having traveled apparently 22 miles in the three previous days, they found themselves in the same latitude as on the 21st. Under these circumstances, Parry resolved to return, which he accordingly did, reaching his ship on the 21st of August. The highest point reached by him was $82^{\circ} 40'$. A new land, about 200 miles north of Nova Zembla, to which the name Franz Joseph Land has been assigned, was discovered by the Austro-Hungarian Polar Expedition of 1872–1874, under Lieutenants Weyprecht and Payer. Its south coast lies about the 80th parallel, and it was explored, by means of sledges, up to $82^{\circ} 5' N.$, while the land was seen extending as far as $83^{\circ} N.$ In 1854, two American explorers passed through Smith's Sound, and reached Cape Constitution in $82^{\circ} 27' N.$ lat., and saw, as they thought, a boundless open polar sea. The *Polaris* sailed in July 1871 from New London, U. S., and reached $82^{\circ} 16' N.$ The supposed polar sea being a sound entering Kennedy Channel, gave hopes of reaching the Pole through Smith's Sound. An English Arctic Expedition under Captain Nares sailed in 1875, and, through Smith's Sound, reached the highest latitude ever attained, $88^{\circ} 20'$. Unable to penetrate further, it returned in 1876. See N. E. and N. W. PASSAGES.

Antarctic Expeditions.—The attempts to penetrate to the south pole are of a very recent date, mainly because a knowledge of the southern polar regions is only valuable to Europeans from a scientific point of view. Cook and Furneaux are the first navigators who are known to have crossed the Antarctic Circle, but the former penetrated only to lat. $71^{\circ} 10' S.$ and neither made any discoveries of importance.

Bellinghousen, a Russian navigator, reached lat. $70' S.$ in 1819, and two years after, discovered Alexander's Land and Peter's

Land, then the most southerly islands known. In 1823, Captain Weddell reached lat. $74^{\circ} 15' S.$, long. $84^{\circ} 16' W.$, and saw beyond him an open sea to the south, but made no important additions to our geographical knowledge. In 1831, Captain John Biscoe discovered Enderby Land; and in 1839, the sealing-schooner, *Eliza Scott*, from New Zealand, discovered Sabrina Land (q. v.); and in the same year, the United States' expedition, under Captain Wilkes, set out on a career of exploration, which resulted in the discovery (January 1840) of what he with reason supposed to be a continuous coast-line, though an ice-line of from 8 to 12 miles in width prevented him from establishing its continuity beyond dispute. The (supposed continental) coast stretched from Ringold's Knoll on the east, to Enderby Land on the west, and was distinguished by the absence of currents to disturb the ice-barrier, and by a much less precipitous character than belongs to islands. In 1840, a French expedition, under D'Urville, discovered a line of coast lying directly south from Victoria (Australia) on the Antarctic Circle. But the most important discoveries of all were achieved by Captain (afterwards Sir James) Clarke Ross, who made three several voyages in 1841–1843, discovering Victoria Land (q. v.), and tracing its coast from lat. 71° to lat. $78^{\circ} 10'$ (the highest southern latitude ever attained). In his third voyage, Ross proved that the lands discovered by D'Urville were islands of inconsiderable magnitude; and his antarctic expedition has besides supplied much important information to the students of natural history, geology, and above all of Magnetism (q. v.). Ross's geographical discoveries have since been confirmed; but a large extent of surface within the Antarctic Circle still remains unexplored.

POLARIZATION OF LIGHT. A ray of light from the sun or a lamp, which has not been reflected or refracted in its course to the eye, possesses no properties by which one *side* of it can be distinguished from another; if, for instance, it be divided into two by a colorless doubly-refracting crystal, such as Iceland spar, these two rays will be of apparently equal intensity in whatever position the crystal be placed (**REFRACTION, DOUBLE**). But if the ray has been reflected from a surface of glass or water, it is found that in general the intensities of the two rays into which it is divided by the doubly-refracting crystal are not only unequal, but dependent upon the position of the crystal with reference to the plane in which the light was previously refracted or reflected. This is a conclusive proof that the light has undergone some change by reflection or refraction, so that it is no longer the same all round, but possesses *sides* (in the language of Newton), or (in modern phraseology) is *polarized*. Perhaps the most complete illustration of this very important fact is to be found by using two doubly-refracting bodies—two small crystals of Iceland spar, for instance—and pasting on a side of one of them a slip of paper with a pin-hole in it. On looking through this crystal, the covered side being turned towards a bright body, we see two images of the pin-hole, *equally* bright. Look at these through the second crystal, each is in general doubled; we see four images of the pin-hole, but these are generally *unequal* in brightness; and by turning either of the crystals round the line of sight as an axis, we find that there are positions, at right angles to each other, in which only *two* images are visible. If we turn further, the lost images appear faint at first, and gradually becoming brighter, while the others become fainter in proportion; till, when we have completed a quarter of a revolution, the new images alone remain, the others having disappeared. From this it follows that each of the rays into which a single beam of light is decomposed by double refraction possesses *sides*, or is polarized; and to such an extent as to be incapable of being again doubly refracted in certain positions of the second crystal.

By taking advantage of the difference of the refractive indices (**REFRACTION**) of the two rays produced by Iceland spar, and the close agreement of one of them with that of Canada balsam, Nicol constructed his 'prism,' which is one of the most useful pieces of polarizing apparatus. It consists of two pieces of Iceland spar cemented with Canada balsam, and allows only one of the two rays produced by double refraction to pass through. When we look at a flame through two Nicol's prisms in succession, we find that the amount of light transmitted depends on their relative position. If they are *similarly* placed, we have the maximum amount—viz., half the incident light; if they are *crossed*, that is, if one be made to rotate through a right angle from the position last mentioned, *no* light, not even the most powerful sunlight, can pass through the transparent combination. There are certain doubly-refracting bodies, such as tourmaline, iodosulphate of quinine, &c., which by absorption stifle one of the two rays into which they divide a beam of light; and which act therefore precisely as Nicol's prism does. But they have the great disadvantage of *coloring* the transmitted light very strongly; and this renders them unfit for the study of the gorgeous phenomena of color (perhaps the grandest displays in optics) which are produced by polarized light. But for the verification of the facts to

which we now proceed, a tourmaline or a Nicol's prism will do equally well, and will be called the analyzer. And first as to the reflection of light, a cause of polarization first detected by Malus.

If we examine by the analyzer light reflected from water, unsilvered glass, polished or varnished wood, jet, &c., we find that it is more or less completely polarized; but that there is a particular angle for each substance, at which if light be reflected (see REFLECTION) from its surface it is completely polarized; that is, can be completely stopped by the analyzer in certain positions, just as a ray which has passed through a Nicol's prism. It was discovered by Brewster that this angle, called the *polarizing angle*, has its tangent equal to the index of refraction of the reflecting body: or, in another form, the reflected light from a surface of glass, water, &c., is completely polarized when its direction is perpendicular to that of the corresponding refracted ray. The light reflected from the second surface of a glass plate is also completely polarized at the same angle; and one of the most useful polarizers which can be made is a pile of thin glass plates, from the surfaces of which light is reflected at the proper angle, which is for ordinary window-glass about 54° . The light which passes through the glass plates is partially polarized, and its polarization is more nearly complete the greater the number of plates employed. And it appears that these rays are polarized in planes perpendicular to each other—i. e., that the analyzer which extinguishes the reflected ray has to be turned through 90° to extinguish the refracted ray.

In order that we may arrive at some ideas as to the nature of polarization, we must consider on the basis of the Undulatory Theory of Light (q. v.) how a ray of light can have sides. If we take, for a comparison, waves of sound, as we know that in them (SOUND) the particles of air move back and forward in the line in which the sound travels, we see that a beam of sound cannot possibly have sides, since the motions of the particles of air in it are precisely the same from whatever side we consider them. Next take waves in water, where we see the water rising and falling as the undulation (not the water) travels uniformly onward in a horizontal direction; and this at once gives the required analogy.

So far as phenomena of Interference (q. v.; see also DIFFRACTION) are concerned, waves, whether in air or in water, present them, so that they merely show us that light depends on undulations, but not the kind of undulation. But when, from the facts of polarization, we find that a ray of light can have sides, we see that the vibrations of the luminiferous medium must be *transverse to the direction of the ray*. Common light, then, consists of vibrations which take place indifferently and in succession in all directions transverse to that of the ray; while light which is completely polarized has its vibrations limited to a *particular transverse direction*. A Nicol's prism allows no light to pass through it except that which vibrates in a particular transverse direction, depending upon the position of the axes of the pieces of Iceland spar of which it is made. Light which has passed through one Nicol's prism is sifted so as to contain none but such transverse vibrations, and will of course pass freely through a second prism; or be completely or partially stopped by it; according as the two prisms are similarly situated, or turned so that the directions of the vibrations they can transmit are inclined at right angles, or any other angle.

It is not yet settled what the direction of these vibrations is in any particular case; whether they take place *in*, or *perpendicular to*, the plane of polarization; and the point is extremely important in the theory of the subject, though not to the explanation of the ordinary experimental results. To explain the nature of this difficulty, we merely mention the simple case of polarization by reflection on a glass plate. Do the vibrations of the reflected ray take place *perpendicular to* the plane of reflection (i. e., parallel to the reflecting surface), or do they take place *in* the plane of reflection? Some high authorities are in favor of the latter hypothesis, but the general opinion of scientific men at present unquestionably leans to the former. Many delicate experiments have been made to decide the question, but their results have been irreconcilable with each other.

From the results which we have just arrived at, it is evident that the oscillations, or vibrations of the luminiferous medium, of which light consists, are similar to those of the bob of a Pendulum (q. v.), the ray in this case being supposed to proceed vertically downwards. Polarized light consists of vibrations analogous to those of the ordinary pendulum, backward and forward in a line. But we have seen that any motion of the pendulum may be compounded of two such motions in planes perpendicular to each other. This is analogous to the decomposition of common light by a doubly-refracting crystal into two rays polarized at right angles. But we find in nature, and can produce artificially, motions of the luminiferous medium resembling exactly the elliptic, and circular, motions of the (conical) pendulum. They occur in nature in all cases of reflection from metallic sur-

faces, and also from the surfaces of highly refractive bodies, such as diamond, &c. The easiest artificial method of procuring them is to allow polarized light to pass through a thin plate of a doubly-refracting crystal, such as a film of mica. Thus, if OA be the direction of vibration of the polarized light, the ray moving perpendicularly to the paper, Oa, Ob, the directions (at right angles to each other) of vibration of the two rays into which it is divided by the mica, we have only to let fall from A perpendiculars on Oa and Ob to determine the extent of the resolved vibrations in these directions. Now if the two rays moved equally rapidly through the mica, they would simply recombine on leaving it into a single plane polarized ray, whose vibrations would be represented by OA as before. But, in general, one of the rays is retarded more than the other, and the combination of two such oscillations is seen by geometrical considerations to give an ellipse whose center is at O, and which touches each side of the rectangle of which Aa and Ab are half sides. The limiting forms of these ellipses are, of course, the diagonals of the rectangle; so that there are two cases for the light remaining plane polarized after passing through the mica, for an infinite number in which it will be elliptically polarized. Also the difference of retardation of the two rays may be such as to correspond to a description of these ellipses either right-handedly or the opposite.

Fig. 1.

In particular cases the ellipse may be a circle; then it is obvious that the rectangle must become a square, that the directions of vibration of the two rays in the mica must be equally inclined to that of the original polarized ray, and that one ray must be retarded an odd number of quarter oscillations more than the other. If it be 1, 5, 9, &c., quarter oscillations, the rotation is in one direction; if 3, 7, 11, &c., it is in the opposite. Circularly polarized light cannot be distinguished by the eye, even with the help of a Nicol's prism, from common light; but by the interposition of a thin plate of a doubly-refracting crystal, phenomena are produced which common light cannot give. Before we leave this part of the subject, it may be remarked that the composition of two equal and opposite circular vibrations produces a plane vibration, whose plane depends upon the simultaneous positions of the revolving bodies in their circular orbits. Hence a plane polarized ray may always be considered as made up of two circularly polarized rays, and if these pass through a medium which retards one more than the other, the plane of polarization of their resultant, when they leave the medium, will in general not be the same as that of the incident ray. In other words, the plane of polarization will have been caused to rotate through a certain angle, which will be proportional to the difference of retardation of its circular components. This is the explanation of what Biot called *Rotatory Polarization* in quartz, turpentine, sugar, &c., and of the rotation of the plane of polarization discovered by Faraday when a polarized ray passes through a transparent body under the action of a magnet.

In the first of these cases the retardation is due to molecular heterogeneity; in the second, it depends upon molecular motions produced by the magnet. The effect is greater in each case the more refrangible the rays; and therefore, when the light which has passed through the medium is examined with an analyzer, the successive colors of the spectrum are cut off each at a different angle, and the observed tint is that compounded of those which remain. The Saccharometer (q. v.), for the determination of sugar in a liquid, is an application of the first case; the second has not as yet been applied to any practical purpose, but it has given most valuable information as to the ultimate nature of magnetism.

When polarized light passes through a slice of any uniaxial doubly-refracting crystal, nearly in the direction of its axis, it is obvious that the difference of retardation of the two rays into which it is divided will depend only upon (1) their refrangibility and (2) their inclination to the axis of the crystal. Hence, if we suppose the light to be homogeneous, the effects of interference, and subsequent application of the analyzer, must be to produce appearances of bright and dark spaces, symmetrically disposed round the axis; that is, a series of concentric circular rings. The superposition of the separate sets of rings, for each color of the spectrum, produces the appearance actually observed; a series of colored rings, like those known as Newton's Rings, due to Interference (q. v.). Besides these, however, there is a dark or bright cross, consisting of two black or white bands, intersecting each other in the common center of the rings. The dark bands are due to the absolute stoppage by polarizer or analyzer, when placed in positions 90° from symmetry, of all light whose vibrations are executed in the principal planes of the polarizer and analyzer. A similar explanation applies to any other case. The system of colored rings thus produced is one of the most splendid results of

optical combinations yet produced; and may be seen by any one by the help of such simple apparatus as two fragments of window-glass and a piece of clear ice from the surface of a pond. In undisturbed freezing, the axis of the ice crystal is perpendicular to the surface of the water, and the cake of ice is therefore, as it were, cut for our purpose. If light be reflected at an angle of about 54° from the first piece of glass, pass perpendicularly

Fig. 2.—Uniaxial Crystal; Black Cross. Fig. 3.—Uniaxial Crystal; White Cross.

through the ice, and be again reflected (at 54°) from the second piece of glass, the phenomena above described, and rudely represented in the annexed cuts, will be at once seen, the appearances varying with the relative position of the planes in which the reflections take place from the pieces of glass. If these planes be at right angles to each other, we have the black cross as in the first figure; if parallel, the white cross as in the second.

If, instead of an uniaxial crystal, a biaxial crystal, such as nitre or arragonite, be employed, the system of colored rings and dark brushes is more complex; symmetry now requiring their arrangement about the *two* optic axes. The general appearance of the rings and brushes depends now, not only on the relative position of the polarizer or analyzer, but also on the position of the crystal (which is no longer symmetrical about an axis) with reference to these planes. The two following figures illustrate the nature of the change due to an alteration of the position of the crystal, the polarizer and analyzer being fixed in planes at right angles to each other.

Fig. 4.—Biaxial Crystal; Black Cross.

Fig. 5.—Biaxial Crystal; Black Cross changed to hyperbolas by rotating the crystal.

By employing circularly or elliptically polarized light, these appearances may be still further varied, but we cannot enter into details.

Every doubly-refracting body produces a change upon polarized light which passes through it. Hence the application of the polarizer and analyzer (usually glass mirrors, or Nicol's prisms) to the microscope is often of very great use in detecting crystal-line, and other structural peculiarities. Solid bodies, such as glass, which are singly refractive, become doubly refractive when strained either by external forces or by unequal heating. A permanent state of strain is produced in glass when it is cooled quickly. All these phenomena are beautifully exhibited by polarized light. Again, the application of polarized light is sometimes of great importance in qualitative analysis, where only an exceedingly small quantity of a substance is procurable for examination, by enabling the chemist to determine whether a minute crystal is doubly refractive or not.

A practical application of a polarizing prism may be mentioned. In salmon spearing it is often exceedingly difficult to see the fish at the bottom of the stream, on account of the glare of light reflected from the surface. But as this light is always partially, sometimes wholly polarized, a great part of it may be arrested by the analyzer held in a proper azimuth; while the light escaping from the water will suffer little loss.

The light of the sky, being mainly reflected light, is of course partially polarized. The investigation of this subject has been most ably conducted by Brewster (*Trans. R.S.E.*, 1862—1863).

POLARITY. The north and south poles of the earth's axis are terms familiar to all; and so are the derived terms of the north and south poles of a Magnet (q. v.). A right-handed and a left-handed corkscrew, or helix, are also perfectly well known. The distinction between the members of any of these pairs leads us to the consideration of polarity, which it is difficult to define except by illustrations. In the case of the helix, it is the difference between right-handed and left-handed; not as in a magnet, the difference between the two ends. If we look closely into the question, we find that it is impossible to define the term 'right-handed rotation' in the abstract. We may define it as being the same as that of the hands of a watch, or that of the apparent motion of the celestial bodies about us *in this northern hemisphere*; but to a person at the equator, or to one who had never seen a watch, such comparisons would be without meaning. In fact, it is impossible to give a definition of even such a simple term as *right, down, east, &c.*, independent of reference to the motion or position of some external object. But there is, in many cases, an important scientific reality underlying, and perhaps causing these difficulties. To a spectator looking down upon the north pole of the earth, the axial rotation would appear to be left-handed, or opposite to that of the hands of a watch; while at the south pole the appearance is the reverse. In fact, as motion in a horizontal straight line appears to be from right to left, or from left to right, according to the side on which the spectator stands; so motion in a curve appears to be right-handed or left-handed, according to the side of its plane from which it is looked at. And this is now known to be the cause of the difference of poles in a magnet; the hypothesis of two magnetic fluids is dismissed, and Ampère's explanation, that in a magnet currents of electricity revolve round each particle in planes perpendicular to the direction of magnetization, at once accounts for the dissimilarity of the poles. Such a figure as this gives a clear idea of the subject.

A little electric current, such as that in the figure, in which positive electricity passes in the direction indicated by the arrow-head, acts upon external bodies exactly as a small magnet would whose axis, is, as in the cut, perpendicular to its plane, the arrow-head representing the north pole; that is, the pole which turns towards the south. Again, an electric current passing in a straight wire would at first sight appear to be altogether independent of polarity; yet it is found that such a current moving in the straight line in the cut, in the direction of the arrow-head, tends to make the north pole of a magnet rotate round it in the direction indicated by the arrow-head in the circle. Again, there are certain crystals, which when heated, become electric. One end of a prism tourmaline, for instance, takes positive, the other negative electricity. Also certain crystals of quartz cause a ray of Polarized Light, which passes along their axis, to rotate right-handedly; others left-handedly. The difference in these cases is due to molecular arrangement, other effects of which are easily seen in the tourmaline, in the dissymmetry of the two terminals of the prism, and, in quartz, in the position of certain small faces of the crystal, so that a preliminary inspection enables us to predict the direction of the effect to be obtained from any particular specimen. The term has various other applications, amongst the least defensible of which is that to light. See POLARIZATION OF LIGHT.

POLDER. a word used in the topography of the Netherlands, is the name given to land below the level of the sea or nearest river, which, originally a morass or lake has been drained and brought under cultivation. An embankment, forming a canal of sufficient height to command a run towards the sea or river, is made, and when carried quite round, as in the case of the Haarlem Lake, it is called the *Ringvaart*. At one or more points on the embankment apparatus for lifting water is placed, and worked by wind or steam-power. If the lake deepens towards the center, several embankments and canals are necessary, the one within the other, formed at different levels as the water-surface becomes lessened, a connection being maintained with the outer canal, which secures a run for the drainage-water. In the Schermer polder, N. Holland, are four canal levels, the land between forming long parallelograms. The water from the inner space is lifted into the first canal; that again, with the drainage of the second section, is thrown into the second, and so on until the outer canal is reached, and a fall obtained. The Netherlands polders are very numerous. The Beemster, a rich district of N. Holland, till 1612 water, is crossed at right angles by fine avenues, and dotted with farm-houses and orchards. In 1865, pop. 3938. The Zype, Schermer, and Purmer are fertile polders, but the most important is the drained Haarlem Lake (q. v.). The land reclaimed amounted to nearly 50,000 acres, and, in 1875, had a pop. of

12,570, with 2867 horses, 5897 head of horned cattle, 7923 sheep, &c. There were in cultivation—colza, 633 acres; madder, 318; flax, 2572; beans, 2353; potatoes, 737; wheat, 4562; rye, 2302; barley, 2145; oats, 12,734; beet, 400; peas, 737; mustard, 95; canary seed, 42; and other crops, 270. In 1874, in the Haarlemmeer were 644 births, 334 deaths, and 95 marriages. In connection with the new canal from the North Sea to Amsterdam, several extensive tracts of land have been reclaimed from the IJ, and formed into valuable polders, some of which are now bearing heavy crops.

POLE, CARDINAL REGINALD, born in Staffordshire in the year 1500, was the son of Sir Richard Pole, Lord Montacute, by Margaret, Countess of Salisbury, daughter of the Duke of Clarence, the brother of Edward IV. His early education was received from the Carthusians at Sheen, whence, being liberally provided for by the king his relative, he passed to Magdalen College, Oxford, and having received deacon's orders, was advanced to several valuable preferments, through the favor of the king, Henry VIII. For the further prosecution of his studies, he went to the university of Paris, and thence to Padua, where he formed the friendship of a distinguished group of scholars and friends, all of whom subsequently took a leading part in public affairs—Contareni, Bembo, Sadoleto, and others. In 1525, he returned to England, where the highest ecclesiastical dignities awaited his acceptance. But it was about this time that Henry had resolved upon the divorce from his queen Catherine, and P. not only withheld his assistance in carrying out the project, but provoked the undying resentment of the king by his well-known treatise, *De Unitate Ecclesiasticâ*. His preferments and pension were withdrawn, and preparations were made for his impeachment. This, and probably still more extreme measures, he evaded by withdrawing from England. The king's resentment fell instead upon his elder brother, and upon his aged mother, the Countess of Salisbury. During the rest of Henry's reign, P. remained in exile. The pope, for the maintenance of whose authority, in the cause of the injured Catherine, P. was regarded as a martyr, treated him with distinguished favor, and elevated him to the cardinalate. He was employed in many affairs of the highest importance, being sent as legate, in 1537, to France and the Low Countries, from both which states Henry VIII. in vain demanded his extradition. He also took an active part in the discussions on the Interim; and when the Council of Trent was opened, he was appointed one of the three legate-presidents who acted in the name of the pope, Paul III. (q. v.).

On this pontiff's death in 1549, P. was all but elected to succeed. For some time after Paul's death, he resided chiefly in a monastery near Verona, in comparative retirement, until the accession of Mary called him back to active life, as the main instrument of the reconciliation of England with the papacy. On November 24, 1554, P. solemnly entered London as legate and plenipotentiary of the Roman see, possessing in an equal degree the confidence of the queen. In the arduous charge thus intrusted to him, he acquitted himself with much prudence, and, considering the circumstances of the time, with singular moderation. In the religious or politico-religious severities which marked the later history of Mary's reign, it is all but certain that P. had no share. He was created Archbishop of Canterbury, and Chancellor of the universities of Oxford and Cambridge. On the difficult and critical question of the disposal of the church property confiscated in the former reign, P., who saw the necessity of moderation, was for a time at issue with the pope; but his representations were successful in producing a more moderate policy, and the work of reunion appeared to proceed with every prospect of a complete permanent issue, when it was interrupted by the death of the queen in 1558. P. died within less than twenty-four hours afterwards. Besides the treatise *De Unitate*, already mentioned, he is also the author of a book *De Concilio*, and of other treatises on the authority of the Roman pontiff and the Reformation of England, and of very many most important letters, full of interest for the history of the time.

POLEXAXE, a weapon consisting of an axe-head mounted on a long pole. There were many varieties of this arm, passing from a great hand-axe to an axe-headed spear or halbert, several of the longer sorts bearing but little resemblance to an axe. In the navy, a pole-axe or boarding-hatchet is a hatchet with a handle about fifteen inches long, and a sharp point bending downwards at the back opposite the blade. It is used for boarding or resisting boarders.

POLECAT, or **FITCHET** (*Mustela putorius*, or *Putorius fœtidus*), a quadruped of the Weasel family (*Mustelidæ*), and commonly referred to the same genus with the weasel, stoat or ermine, &c. It is the largest British species of that genus, the length of the head and body being about a foot and a half, the length of the tail more than five inches, the form stouter than that of the weasel or of the ermine. Its color is a deep blackish brown; the head, tail, and feet almost black, the under parts yellowish, the ears

edged with white, and a whitish space round the muzzle. The hair is of two kinds—a short woolly fur, which is pale yellow, or somewhat tawny; and long shining hairs of a rich black or brownish-black color, which are most numerous on the darkest parts. The nose is sharp, the ears short and round, the tail pretty equally covered with longish hair. There is a pouch of follicle under the tail, which exudes a yellowish, creamy substance of a very fetid odor; and this odor is particularly strong when the animal is irritated or alarmed. Hence, apparently, its name *Foumart* (*Foul Marten*), which, with various provincial modifications, as *Fulmart*, *Thoumart*, &c., is prevalent in most parts of Britain. The origin of the names P. and Fitchet is much more uncertain.

The P. was much more common in Britain in former times than now, and is almost extirpated in some districts, through the constant war waged against it by gamekeepers and others. It

Polecat (*Mustela putorius*).

eats everything the gamekeeper wishes to preserve. It is extremely destructive in the poultry-yard, the abundance present there inviting it to drink blood and eat brains, which seem to be its favorite luxuries. The rabbit is followed by the P. into its burrow, and its ravages among poultry are partly compensated by its destruction of rats.—The taming of the P. does not seem to have been attempted. The smell prevents it.—The skin is imported from the north of Europe under the name of *Fitch*, and is used as a kind of fur, similar but inferior to that of the Marten (q. v.). It is imported to some extent from the north of Europe. To artists, the hair of the *fitch* or *fitchet* is well known as that of which the best brushes are made; the hairs used for this purpose being the long hairs already noticed, which grow through the light-colored fur of the animal.—The Ferret (q. v.) is supposed by some to be a variety of the polecat.—A dark-colored kind of ferret is commonly regarded as a cross between the P. and the ferret, and is sometimes called the *Polecat-ferret*. The P. breeds in May or June, making its nest in an old rabbit burrow or similar hole, and producing four, five, or six young.—In North America, the Skunk (q. v.) is called polecat.

POLEMONIA'CEÆ, a natural order of exogenous plants, allied to *Convolvulaceæ*, and containing more than 100 known species, natives of temperate countries, and particularly abundant in the north-western parts of America. They are mostly herbaceous plants, with alternate and often pinnate leaves; regular hermaphrodite flowers; 5-cleft calyx; 5-lobed corolla; 5 stamens, springing from the tube of the corolla; the ovary free, surrounded with a fleshy disc; the style surmounted by a 3-cleft stigma; the fruit a capsule with 3 cells, and 3 valves; the seeds often enveloped in mucus, which contains spiral threads. Some of the species are favorite garden flowers, as *Polemonium cœruleum*, *Cobœa scandens*, and species of *Phlox*, *Ipomopsis*, *Gilia*, &c. None are of value otherwise. *Polemonium cœruleum*, the only British species, and a rare plant in Britain, is well known in gardens by the curious name of *Jacob's Ladder*. It is also called *Greek Valerian*. It is not supposed to be really the *Polemonium* of the ancients, to which great medicinal virtues were ascribed by them. It has a stem from one to two feet high, pinnate leaves, and a panicle of blue (or white) flowers.

POLE'NTA, a preparation of Semolina (q. v.) or of Indian corn or maize meal, which is used as food by all classes in Italy. By the poorer classes, maize is universally used. The material is mixed with milk or water, and boiled until it is just thick enough to pour out into a dish, in which it becomes as firm as a thick jelly. Cheese is grated over it, and other condiments are added according to taste, and it is cut out in slices, and either eaten at once, or sometimes the slices are lightly fried in oil or butter. Semolina being much more expensive, is only used by the wealthier people, and many ingredients are added to suit their tastes.

POLE-STAR, or **POLARIS**, the nearest conspicuous star to the north pole of the celestial equator. The star which at the present time goes under the name of the 'pole-star' is the star α in the constellation of Ursa Minor. By examining attentively the general movement of the stars throughout a clear winter's night, we

observe that they describe circles which are largest at the equator, and become smaller and smaller as we approach a certain point (the north pole of the celestial equator), close to which is the star above mentioned. This 'pole-star' is, however, a little less than $1\frac{1}{2}^\circ$ from the pole, and has a small but sensible motion round it. See **POLES**. Owing to the motion of the pole of the celestial equator round that of the ecliptic (see **PRECESSION OF THE EQUINOXES**), this star will in course of time (about 2100 A.D.) approach to within $28'$ from the north pole, and will then recede from it. At the time of Hipparchus (156 B.C.), it was 12° , and in 1785, $2^\circ 3'$ from the north pole. Its place can easily be found in the heavens, for a line drawn between the stars α and β (called the two *pointers*, from this peculiarity) of the constellation *Ursa Major*, or the Great-Bear, and produced northwards for about $4\frac{1}{2}$ times its own length, will almost touch the pole-star. Two thousand years ago, the star β of *Ursa Major* was the pole-star; and about 2800 years before the Christian era, the star α in the constellation of the Dragon was not more than $10'$ from the north pole; while 12,000 years after the present time, the bright star *Vega* in *Lyra* will be within 5° of it.

The south pole of the celestial equator is not similarly marked by the near neighborhood of a bright star, the only star deserving the name of the south pole-star being of the sixth or least visible magnitude.

POLES (Gr. *polos*, a turning-point), in *Geography*, are the two extremities of the axis round which the earth revolves; they are therefore situated the one on the north, and the other on the south side of the equator, and equidistant from all parts of it, or in lat. 90° N. and lat. 90° S. They are called the north and south poles of the earth.—In *Astronomy*, the poles, which, for distinction's sake, are frequently denominated 'celestial poles,' are those points in the heavens to which the earth's axis is directed, and round which the heavens seem to revolve. The celestial poles are valuable points of reference to astronomers and geographers, so that the determination of their position in the heavens is a matter of the utmost importance. Unfortunately, no stars mark their exact situation (see **POLE-STAR**)—though there is a minute telescopic star only a few seconds from the north pole, which may be employed instead of it in rough observations—and therefore it is necessary to adopt some means for discovering its precise position. This is effected in the following manner: A bright star (generally the pole-star) is selected, and its position in its upper and its lower *Culminations* (q. v.) is accurately noted; the point midway between these two positions of the star is the pole of the heavens. The observation of the star's two positions must be corrected for refraction, and it is for this reason that the pole-star is selected, since the effect of refraction is much the same in both positions of the star. The term 'poles' has, however, a wider application, as denoting the extremities of a line passing through the center of a great circle perpendicular to its plane; thus, we have the poles of the horizon (*viz.*, the zenith and nadir), the poles of the ecliptic, the poles of a meridian; and in the same sense, the terrestrial and celestial poles are spoken of as the poles of the equator and equinoctial respectively.—**Pole**, in *Geometry*, is used in a very indefinite sense; and in *Physics*, it denotes those points of a body at which its attractive or repulsive energy is concentrated. See **POLARITY** and **TERRESTRIAL MAGNETISM**.

POLIA'NTHESES. See **TUBEROSE**.

POLICE (Lat. *politia*, Gr. *politeia*, civil government; from *polis*, a city), are constables or peace-officers appointed in all parts of town and country for the purpose of watching property and detecting crime, and arresting offenders and maintaining public order. Though the word policeman is now, especially in towns, a household word, the legal denomination is that of constable; but he is a paid constable, to distinguish him from unpaid constables and special constables. In each parish in England, the justices of the peace have power to appoint constables to act gratuitously and compulsorily; but the vestry has power to resolve that one or more paid constables shall be appointed, in which case the justices are to make the appointment, and these paid constables supersede the unpaid constables. The salary of these parish constables is paid out of the poor-rates of the parish by the overseers. The justices also appoint a superintendent constable for each petty sessional division, to settle the fees and allowances which are to be paid to the constables for the service of summonses, and for the execution of warrants incidental to the office of justices of the peace. In all boroughs in England, the corporation is empowered, by the Municipal Corporation Acts, to appoint a watch committee, who appoint a sufficient number of men to act as constables. The treasurer of the borough pays their salaries, wages and allowances, as well as extraordinary expenses incurred by them. By an act of parliament applicable to counties, the justices are empowered to establish a sufficient police force for each county, and a chief constable is appointed to govern the whole.

The duties of constables or police-officers are exceedingly mul-

tifarious, and they receive printed regulations to guide them in the proper discharge of such duties. They have important duties in reference to the apprehension of offenders, and their powers are necessarily larger than those of private individuals. Whenever a person is seen in the act of committing a felony, it is the duty of every one, not merely of constables, to apprehend him or her without any warrant, for no warrant is needed. Persons found offending in many misdemeanors may also be apprehended by anybody without a warrant; but in other cases, a constable only can make an arrest. In case of a riot, any body may arrest the rioter. Constables are bound to arrest hawkers trading without a license; and vagrants who are offending against the Vagrant Acts, such as telling fortunes, loitering about premises, &c. The powers of constables are much greater than those of individuals with reference to crimes after they are committed. Thus, where the constable has not seen the offence committed, but is merely told of the fact, and he has reason to believe it, he is entitled to arrest the party charged without any warrant; he must, however, in such cases act only on reasonable suspicion. He is not justified, for example, in apprehending a person as a receiver of stolen goods on the mere assertion of the principal felon; nor is a constable justified in taking a person into custody for a mere assault without a warrant, unless he himself was present at the time the assault was committed, or reasonably apprehends a renewal of it. If a constable have a reasonable suspicion that a man has committed a felony, he may apprehend him; and so a private individual may do so. The difference between the authority of the constable and the private person in this respect is, that the latter is justified only in case it turn out that a felony was in fact committed; but the constable may justify the arrest and detention whether a felony was committed or not.

It is the duty of a constable to raise a hue and cry in search of a felon, and all private individuals are bound to join in it, otherwise they may be indicted and fined. An arrest by a constable is usually made by laying hands on the party, and detaining him; but it is enough for the constable to touch him and say: 'I arrest you, in the Queen's name.' If the party arrested be in a house in hiding, the constable may demand admittance, and if he is refused, may then break open the doors; this is so in all cases where the party has committed treason or felony, or has dangerously wounded another. In cases where the constable is not authorized at common law or by some statute to arrest a party without a warrant, then he must produce a warrant signed by a justice of the peace, and show it to the party if it is demanded; and if the constable happens not to have the warrant in his pocket at the time, even though it is not asked for, it is an illegal arrest. When a party is arrested, it is the duty of the constable to take him without any unreasonable delay before a justice of the peace, and meanwhile lodge him in safe custody. The party arrested must not be treated with harshness beyond what is necessary for safe custody, and therefore it has been held that a constable has no right to handcuff a person whom he has apprehended on suspicion of felony, unless such person has attempted to escape, or it be necessary to prevent an escape. Nor has a constable in general a right to search a person apprehended, unless the latter conduct himself violently.

The conduct of constables in reference to public-houses is of some importance. It is an offence in publicans and beer-house keepers, and indeed the keepers of all places of public resort, to refuse to admit the constable into such house or place at any time. Thus, in the case of these places being open on Sundays at the times prohibited by statute, the constable, if he suspect that the act is being violated, may demand admittance, and thus satisfy himself as to the fact. It is owing also to this power of a constable to enter at all times, that he is enabled to detect other offences in public-houses, such as harboring prostitutes and disorderly characters. Constables, when suspecting that a betting-house is kept, must first get a warrant from a justice of the peace, which can be obtained without notice to the parties, and can then break into the house. So as to gaming-houses. While constables have summary power of entering public-houses, still this is not to be abused; and it is a distinct offence in the keepers of all public places where wine, spirits, beer, cider, or any fermented or distilled liquors are sold on the premises, to knowingly harbor, or entertain, or suffer to remain there such constables during the time they are on duty, except when quelling disturbances or restoring order. It is an offence punishable with more than usual severity to assault constables when in the execution of their duty. Though constables are paid in great part by each county and borough, and thus by the public at large, it is often requisite for individuals to require the services of extra constables, in which case such individuals must pay for them at their own expense, as is usual in theaters and large establishments. Of late years, considerable complaint had been made as to constables interfering in the protection of game-preserves and fisheries, it being considered that the owners of those properties ought to bear the extra charge, if required, of the constables' giving more than the ordinary at-

tention to poachers. But by the recent Act, extended powers of detecting poachers of game were given to constables, who are now entitled, whenever they suspect people on the highway of being engaged in poaching, to stop and search them, and then summon the poachers, if necessary, before justices. See POACHING.

In 1880, the total police and constabulary in England and Wales amounted to 31,480 men. These are subdivided into chief constables of counties, 56; head constables of boroughs, 168; superintendents, 521; inspectors, 1311; sergeants, 3008; constables, 25,511; additional constables, 390; detectives, 520. The proportion of policemen to the population is about 1 to 811. In 1879–80, the total expenditure on the police force of England and Wales, including the city of London police, was £3,113,725, of which less than £600,000 was paid by Her Majesty's Treasury and the Superannuation Fund, the major part coming from local sources. The public revenue pays nothing towards the city of London police; it pays all the cost of the dock-yard police; it pays nearly one-fifth of the other branches of the police. In 1881, the metropolitan police numbered 1 chief superintendent, 24 superintendents, 605 inspectors, 941 sergeants, and 9634 constables; the city police comprising 124 officers and 737 constables.

In Ireland, the first regular police force was established in 1814, which was improved in 1836 and 1839. Originally, the expense was defrayed partly out of the Consolidated Fund; but in 1846, the whole expense was borne by the Consolidated Fund, with trifling exceptions. In 1880, the total cost of the constabulary of Ireland amounted to £1,095,121. The number of constables in 1880 was 11,473, besides 1111 Dublin Metropolitan Police. In Ireland the police carry firearms.

In Scotland, the public police force was, in 1880, 3702 (1331 for counties, 2371 for burghs), including 84 detectives; and their cost for the year was £316,413. In addition to this number, the Tweed Commissioners pay for about 30 constables; 12 more are paid by other fishery commissioners, 20 employed by companies or private persons, and 160 by harbor boards.

POLICE, MILITARY, has two significations—1st, the organized body employed within an army to preserve civil order, as distinct from military discipline; and 2d, a civil police with a military organization. The police of an army commonly consists of steady intelligent soldiers, who act under the orders of the provost-marshal, and arrest all persons out of bounds, civilians not authorized to pass the lines, disorderly soldiers, &c.; they also attend to sanitary arrangements. As in all military matters, the police of an army possess summary powers, and a sentence of the provost-marshal is carried out immediately after it is pronounced.

Of civil police with military organization may be instanced, as specimens, the Gendarmerie (q. v.) of France, the Sbirri of Italy, and, in an eminent degree, the Irish constabulary.

PO'LYCY (a corruption of the Latin *polyptycha* [analogous to *diptycha*, i. e., two-fold or a pair of tablets] applied in the middle ages to memoranda or registers, written on a set of several tablets), as a legal term, denotes the contract of insurance (Ital. *polizza d'assicurazione*). The usual contracts are for the insurance of life, or rather against the risk of death, against fire, against loss of a ship; but the same name is given to a similar instrument adapted to meet any other risk. See INSURANCE.

POLIGNAC, an ancient French family which takes its name from a castle said to have been built in the 5th c., on a rock of the Cevennes, near Puy-en-Velay, in the department of Haute-Loire, on the site of a Roman temple dedicated to Apollo, whence—according to rather credulous genealogists—the castle was originally called *Apollonique*, of which Polignac is affirmed to be only a later corruption. The first of the Polignacs who acquired celebrity was MELCHIOR DE P., younger son of ARMAND, 16th MARQUIS DE P., and born at Puy-en-Velay, 11th October, 1661. Destined by his parents for an ecclesiastical career, he received an excellent education at Paris in the colleges of Clermont and Harcourt.

In the negotiations of Cardinal de Bouillon with Pope Alexander VIII. at Rome in 1689, the young, but astute and insinuating abbé took a principal part. In 1695, he was sent to Poland as French ambassador, when John Sobieski was dying; and diplomatized and intrigued so cunningly in favor of Prince de Conti, that the latter was actually elected his successor. Events, however, frustrated this policy, and both Conti and P. had to leave Poland rather precipitately, in consequence of which the latter lost the royal favor. He now retired to his abbey at Bonport, where he spent the next four years, partly occupied in the composition of a Latin poem entitled *Anti-Lucretius*, which was intended as a refutation of the scepticism of Bayle. It appears to be a very respectable and even able performance. In 1702—after a stroke of his usual neat flattery—he was recalled to Versailles, and rose higher into favor than ever. Named *Auditeur de Rote* in 1706, he was sent to Rome, where he devoted himself to the study of canon and civil law, was associated in the negotiations of Cardinal de la Trémoille, and honored with the friend-

ship of Pope Clement XI. In 1712, he was appointed French plenipotentiary at the Congress of Utrecht; and after his return, obtained the abbey of Corbie and Anchin. When Louis XIV. died, P. was at the top of his reputation and influence. During the regency of the Duke of Orleans, he took part in the conspiracy of Cellamare, and was banished to his abbey of Anchin. In 1720, he was sent to Rome, charged with the conduct of French affairs, and remained here for about ten years, and signalized his mission by healing the quarrel that was dividing the Gallican Church on the subject of the famous bull *Unigenitus*. In 1726, he was raised, in his absence, to the archbishopric of Auch; and on his return to France, spent the remainder of his days in literary repose, and in the high esteem of courtiers, scholars, and the like. He died 3d April 1742. P. succeeded Bossuet at the *Académie Française* in 1704, and became an honorary member of the *Académie des Sciences* (1715) and of the *Académie des Belles-lettres* (1717). See C. Faucher's *Histoire du Cardinal de Polignac* (2 vols., Paris, 1772), St. Simon's *Memoires*, and D'Argenson's *Memoires*.

The other members of the Polignac family who have an historical name at all are more notorious than noteworthy. In the reign of Louis XVI., TOLANDE-MARTINE, GABRIELLE DE POLASTRON, DUCHESS DE P. (born 1749; died at Vienna, 9th December 1793), and her husband JULES, DUC DE P. (died at St. Petersburg, 1817), were among the worst, but unhappily most favored advisers of Marie Antoinette. They obtained vast sums of the public money from their royal master and mistress, and were largely, if not mainly responsible for the frightful pecuniary extravagance of the court. The discovery of the famous *Libre Rouge* occasioned the exulting cry of Mirabeau: *Mille Ecus à la Famille d'Assas pour avoir sauvé l'Etat; un Million à la Famille Polignac pour l'avoir perdu!* The Polignacs—knowing the deep hatred felt towards them by the French people—were the first of the noblesse to emigrate (16th July 1789). From the Empress Catharine of Russia, the duke received an estate in the Ukraine, and did not return to France at the Restoration. He left three sons and a daughter, of whom only one has become historical—AUGUSTE JULES ARMAND MARIE, PRINCE DE P. (born at Versailles, 14th May 1780). On the Restoration, he returned to France; became intimate with the Comte d'Artois, afterwards Charles X.; showed an ardent attachment to the Church of Rome—or at least to its policy—and, in consequence, received from His Holiness, in 1820, the title of Prince; was appointed ambassador at the English court in 1823; and finally, in 1829, became head of the last Bourbon ministry, in which capacity he promulgated the fatal ordinances that called France to arms, and drove Charles X. from the throne. He then attempted to flee from the country, but was captured at Granville on the 15th of August; was tried, and condemned to imprisonment for life in the castle of Ham, but was set at liberty by the amnesty of 29th November 1836. He took up his residence in England, but died at Paris, 2d March 1847.

POLISH LANGUAGE AND LITERATURE. The Polish language is one of the most widely-spread branches of the Slavic, forming (according to Dobrowsky), along with the Bohemian, the western branch. It surpasses almost all the other Slavonic tongues in euphony and flexibility, and is scarcely excelled by any language in point of brevity. It does not make use of the article, but has a most elaborate declensional system, comprising seven cases. The conjugation of the verb is equally elaborate, and enables a Pole to express transitions and delicate niceties in the conditions of time and gender quite unknown to the French, or German, or English verb. The Polish vocabulary is also uncommonly rich. The number of harsh consonants in the language, it must be admitted, is large, and this fact is a marked distinction between it and its eastern sister, the Russian, but in pronunciation, these are so much softened that its euphony is preserved. It alone of all the Slavic dialects, with exception of the old Slavic Church language, has two nasal sounds; one like the French *on*, the other like the French *in*. The letter *ł* has also a peculiarly broad snarling sound. After the introduction of Christianity, Latin, the language of the church, exercised a powerful influence on its structure and development, and subsequent to the 14th c., it adopted into its vocabulary numerous German words. In the 16th c., Polish, as a written language, rapidly attained so high a degree of perfection that it supplanted even Latin itself, until then the language of the state and of the learned. The best Polish grammars are those of Mrongovius (3d ed., Danz. 1837), Bandtke (Breslau, 1824), Muczkowski (Crac. 1845), and Boock-Arkossy (1866); the most comprehensive dictionary is that of Linde, after which rank those of Bandtke (2 vols., Breslau, 1806), Mrongovius (Königsb. 1835), Trojanski (4 vols., Posen, 1835–1846), and Liebkind (1855).

The history of Polish literature is divisible into five clearly marked periods. The first extends from a date antecedent to the introduction of Christianity down to the close of the 15th century.

Of pre-Christian Polish literature, nothing has survived but some popular songs and proverbs. Among the very oldest literary monuments is a hymn to the Virgin Mary, ascribed to St. Adalbert. The introduction of Christianity paved the way for a Latin literature more or less ecclesiastico-historical. Casimir III. (q. v.), surnamed the Great, did more than any other early Polish monarch for the encouragement of literature, and, among other things, founded the university of Cracow, which, from the beginning of the 15th c., long continued to be the center of intellectual life and culture in Poland. To the 15th c. belong Jan Długosz (Lat. *Longinus*), author of a most interesting and valuable *Historia Poloniae*, in 13 books, and otherwise worthy of remembrance as an able diplomatist and philanthropist; also Jan Laski, Archbishop of Gnesen (b. 1457, d. 1531), whose collection of the oldest Polish laws, *Commune Incoliti Poloniae Regni Privilegium*, is of great historical importance. In 1490, the first printing-press in Poland was established at Cracow.

The second period of Polish literature embraces the 16th and first quarter of the 17th c., and is marked by the use of the Polish as a written language. The reigns of Sigismund I. and Sigismund II. Augustus, are regarded as the golden era of Polish literature, properly so called. The series of poets begins with Nikol. Rej (b. 1515, d. 1568), commonly called the *Father of Polish Poetry*, a native of Zorawno, in 'Little Russia,' and educated at Lemberg and Cracow. He spent his life at the court of the Sigismunds. His principal works, *Wizerunek Żywota Oslowieka Poczewnego* (Crac. 1560) and *Apophthegmata* (Crac. 1568), are full of sharp wit and strong satire, and though the language is rough and unpolished, it is genuinely poetical.

After Rej, the brothers Jan and Piotr Kochanowski hold the highest rank. Szymonowicz or Simonides (d. 1629) acquired by his Latin odes the name of the 'Latin Pindar;' and his *Sielanki* ('Idylls,' new ed. Leip. 1837), modelled on those of Theocritus, exhibit a charming simplicity of style. Still more original, if scarcely so graceful, are the *Sielanki* (new ed., Leip. 1836) of his friend Zimorowicz (d. 1629). Sebastian Klonowicz, called *Aceruus* (d. 1608), is celebrated as a satirist and descriptive poet. The Reformation, which rapidly made way in Poland, being tacitly approved of by the rulers and magnates, gave a powerful stimulus to the intellectual and spiritual activity of the nation—visible in translations of the Bible, hymn-books, and an important pulpit or sermon literature. Among the historians of this period, the most celebrated are the brothers Bielski; Lukas Górnicki (d. 1591), author of a history of the Polish crown (*Deiue w Koronie Polskiej*, Crac. 1637, Wars. 1804); Strzikowski (d. 1582), whose *Chronicle of Lithuania* (Königsb. 1582) is an admirable work; and Paprocki (d. 1614).

The third period of Polish literature, extending from 1620 to 1750, is coincident with the rule of the Jesuits, who first obtained a footing in Poland about 1566, through the influence of Cardinal Hosius, soon possessed themselves of the schools, and, on the whole, seriously checked the literary and religious growth of the nation. The most conspicuous poet of this retrogressive period is the Jesuit Kazimierz Świebski (1595–1640), who wrote only in Latin; others more or less noteworthy are Kochowski (died about 1700); Twardowski (d. about 1660); Opalinski (d. 1655); Chłosciński, the translator of Lucan; Morsztyn, the translator of Corneille; and Elzbieta Drużbacka (d. 1760). Among the historians of this period, it may suffice to mention Strarowski (d. 1656), author of *Polonia, sive Status Regni Poloniae Descriptio* (Wölfenbützel, 1656), and other works; Kojalowicz, a Jesuit (d. 1677), and Kaspar Niesiecki, a Jesuit (d. 1745), whose *Korona Polska* (4 vols., Lemb. 1728–1743) is the most important work on Polish heraldry.

The fourth period, commencing with the middle of the 18th c., and extending into the first quarter of the 19th, owes its characteristics partly to the influence of the French literature of Louis XIV.'s time; partly also to the liberal patronage of literature and science by king Stanislas Augustus, the princess Czartoryski, Jablonowski, and other magnates, and the educational reforms of Stanislas Konarski (b. 1700, d. 1773). The good work begun by Konarski was carried on by Kopczynski (1735–1817), who was the first to thoroughly establish on a scientific basis the grammar of the Polish language in his *Grammatyka Narodowa*; by Piramowicz (d. 1801); by Bohomolec, the Jesuit, who translated a multitude of stage-plays from the French; but above all, by Adam Stanislas Naruszewicz, the accomplished translator of Tacitus; and Ignacy Krasicki (1735–1801), called the 'Polish Voltaire,' the center of the whole Polish literature of his age, whose satires and fables are reckoned the first in his native language. As poets of this Renaissance period, occur the names of Trembecki; Cajetan, Wegierski, Godebski, and Węzik. The most noted dramatist is Boguslawski (d. 1829), who wrote about 80 plays—the majority of which, under the title of *Dezela Dramatyczne*, were published at Warsaw (9 vols., 1820).

The political storms that swept over Europe at the close of the 18th and the first years of the 19th c., did not quite destroy the

new literary life that had burst into blossom under Stanislas Augustus.

In 1801, the historian Tadeusz Czacki, Franciszek Dmochowski, and Bishop Jan Albertrandy founded at Warsaw the 'Society of the Friends of Knowledge,' which, especially under the auspices of the state-councillor Staszcz, bore good fruit till it was dissolved in 1832, when its library of 50,000 vols. was carried off to St. Petersburg. At the same time, Jozef Maximilian Ossolinski, Hugo Kolontaj, and Stanislas Potocki, by word and writing exercised a mighty influence on the renovation of the national spirit. The transition of this *newest* or fifth period was made by Karpinski (1745–1825), whose *Songs and Idylls* (4 vols., Warsaw, 1804; new ed., Leip. 1836) live on the lips of the Polish people; by Chancellor Voroniez (1757–1829), a richly imaginative poet and a great orator; by Niemcewicz (1757–1841), a statesman, soldier, and author of celebrity in his own land; and by the poet Kasimierz Brodzinski (1791–1835). At Wilna, which, after 1815, became the center of Polish literary activity, and a rallying-point for all the enthusiastic spirits of the land, several young men united, with Adam Mickiewicz (b. 1798) at their head, in a crusade against the still dominant French style of literature. We can only name some of his numerous and brilliant associates, as Malczewski (1792–1826), whose best production is his epic-lyric narrative of Ukraine life, entitled *Maria*; Goszczynski (b. 1806; Poems, 3d ed., Breslau, 1852); Bohdan Zaleski (b. 1802; *Poezye*, Pos. 1841, and later); Tomasz Padura (*Pienia*, Lemb. 1842); Odyniec (*Poezye*, Pos. 1833); Korsak (*Poezye*, Pos. 1833); Chodzko (*Poezye*, Petersb. 1829); Groza (*Poezye*, Wilna, 1836); Lucyan Siemieniński (b. 1809), an excellent novelist and translator; Bielowski (b. 1806), a lyric poet and translator; Gorecki, renowned for his pungently sarcastic fables (*Bajki i Poezye nowe*, appeared at Paris in 1833); Garczynski (*Poezye*, Paris, 1833); and Slowacki, the most fertile of all the recent Polish poets.

Most of these writers became either 'banished men,' or men who, while living, were forced to expatriate themselves. They belonged to the 'Polish Emigration,' whose headquarters was Paris. The most many-sided and prolific of all the modern Polish novelists is Jozef Ignacy Kraszewski, who was born at Warsaw in 1812. The new national tendency of Polish literature, which naturally first showed itself in poetry, soon became visible in other departments also. Thus, Joachim Lelewel (born in 1786) rose to the first rank as a writer of Polish history, and a study of his works is absolutely indispensable to a knowledge of that subject; next to him (and later) in the same department stand Bandtke, Maciejowski, Count Raczyński, and Count Plater. Narbutt of Wilna wrote a very solid and comprehensive work on Lithuanian History (Wilna, 1837 *et. seq.*), and Lukaszewicz of Posen has furnished numerous important contributions to the history of the Reformation in Poland. A multitude of works more or less weighty have been devoted to a record of the revolution of 1830, chiefly, of course, by Polish emigrants. In philosophy, theology, and physical sciences, Poland has nothing of consequence to show.—The principal works on Polish literature are those of Muczkowski, Bentkowski, Ossolinski, Chłodyński, Lukaszewicz (Posen 1860), and the comprehensive *Historia Literatury Polskiej* (Crac. 1840, *et. seq.*) of Wisniewski.

POLISHING MATERIALS. See DIAMOND-GRINDING, EMERY, PASTES, and PUTTY-POWDER.

POLISHING OF METALS. This is effected by first removing any tarnish or oxidation by means of some material which will chemically act upon it; for this purpose, sulphuric, hydrochloric, oxalic, and acetic acids are used to different metals, and in various states of dilution. Usually, it is necessary to remove the acid with clean water, and dry rapidly, to prevent re-oxidation; and then either friction with various polishing materials, or rubbing with a smooth hard surface or burnisher, brings out the lustre of the metal.

POLISHING OF STONE. See STONE-CUTTING.

POLISHING SLATE, a mineral composed chiefly of silica, with a little alumina, lime, oxide of iron, and water; white, yellowish-white, or yellow; and of specific gravity about half that of water. It is found in Bohemia, Saxony, and Auvergne, and is supposed to be a volcanic product. It is used for polishing glass, marble, and metals.

POLISTENA, a town of South Italy, province of Reggio, Calabria. The village which occupied the site of the present town was totally destroyed by an earthquake in 1788. Pop. (1871) 7559.

POLITICAL ECONOMY. The word economy is derived from the Greek for house-law or house-regulation. It refers to the material portion of domestic regulation, and does not, for instance, embrace the observance of religion or the communication of instruction. The most important part of it is the adjustment of the expenditure of the household to the income at their command. Hence the word economy is sometimes applied, both in a public and a private sense, to the saving of money. The term

'Political' came to be used along with it as a convenient method of expressing the application to a state of a sound system of management in relation to its affairs. In later times, however, the word, as applied to a community, came to be something totally different from its application to a household. It was thought that one could regulate a people just as a house is regulated, by adjusting the spending and the getting of the national wealth. Hence arose several doctrines now discredited—such, for instance, as 'the balance of trade,' which taught that the trade with any nation is only profitable when you sell more to that nation than you buy from it; the system of bounties upon special trades, as being more profitable to others; and lastly, the system of protection to native industry—the last relic of what may be called the positive school of economists.

Political economy now means, not the art of regulating communities in this respect, but the science of those laws which Providence has established for their regulation. Hence the analogy with domestic economy ceases. Domestic economy is the positive regulation of a household—not the leaving of it to follow its own dictates; and, indeed, that there is a disposition, more or less in the head of every house, to limit its expenditure to its income, is one of the phenomena by which things right themselves, as it were, and make up those laws of nature which constitute political economy. A man knows that if he buys too much, he will become bankrupt; but we do not now order the wholesale merchant not to buy too much from this or that country, so as to place the balance of trade against us—we know that this naturally rights itself, because we must expect our own produce to pay for what we bring in. Even if we should have to pay for it in gold, that is a commodity produced by our people. The income and expenditure of the government, as apart from that of the people of the community, are of course under regulation like those of a household; but these form a separate field of operation, called Finance (q. v.). There are a few people who still hold that there is no natural system sufficient in itself to regulate the material affairs of mankind, and that these should be committed to the hands of special managers. Finding the approved doctrines of political economy going further from their direction, such persons, though few in number, have been very absolute in their views, and zealous in pushing them. One class of these are called Socialists; and another, who go further lengths, are called Communists. It has not yet been considered necessary here to go beyond the mere description or definition of the nature of political economy, because the various parts of which it consists are given each under its own head, as BOUNTY, CAPITAL, COLONY, COMMUNISM, COMPETITION, CORN LAWS, DEMAND AND SUPPLY, EXCHANGE, FREE TRADE, LABOR, MONOPOLY, NAVIGATION LAWS, RENT, VALUE, &c.

POLITICAL OFFENCES, crimes considered injurious to the safety of the state, or such crimes as involve a violation of the allegiance due by the subject to the supreme authority of the state.

By the Roman law, in the early times of the republic, every act injurious to the state was comprehended under the name *perduellio*, and visited with death. That term included conspiracy against the government, aiming at kingly power, aiding the enemies of Rome, and losing an army. The word *perduellio* afterwards fell into gradual disuse, and the chief state offences were known by the term *majestas* or *crimen lase majestatis*, somewhat akin to the treason of modern times. In the republican period, the crimes to which the epithet *lase majestas* was most frequently applied, were the betrayal or surrender of an army to the enemy, the excitement of sedition, and such a course of administration as impaired the dignity of the state. In imperial times, acts and words disrespectful to the reigning emperor were included, and an indignity to his statue was visited nearly as severely as an offence against his person. *Lase majestas* was generally punished with death, confiscation, and infamy. The criminal might even be tried after his death, to the effect of confiscating his property, and rendering his memory infamous—a practice which has been resorted to both in France and Scotland as late as the beginning of the 16th century.

In modern times, the acts brought under the category of political offences have varied much at different periods and in different countries. They have in general been more leniently dealt with under constitutional than under despotic governments. It is, however, a principle which has been generally recognized by the most constitutional of governments, that when the legislature thinks itself endangered by a secret conspiracy against the state, or an understanding with the enemies of the country, it permits the executive, for a limited time, to arrest suspected citizens, without the formalities which are required in ordinary circumstances.

In England, a large number of the graver political crimes are included under the denomination of Treason, and the treason law has sometimes been stretched so as to include offences which, by a fair construction, could hardly come within it, such

as the use of violence to reform religion or the laws, or to remove the councillors of the sovereign. Even riotous assemblies with the object of destroying all property of a particular class have been held treason. Political offences also include a number of crimes against government falling short of treason, and passing under the name of Sedition, which, though they have for their ultimate object the violation of the public peace, do not aim at direct and open violence against the laws or the sovereign, but rather the dissemination of a turbulent spirit tending to produce such violence. The British government does not permit the political offenders of other countries to be included in extradition treaties; and in modern times, generally speaking, extradition does not apply to political offenders; contrary to the doctrine laid down by Grotius. In some countries, conspiracy against the sovereign of any country in league with the state is a special offence; in Great Britain, however, this seems not to be the case. A bill introduced in 1858 to make it felony to conspire to commit a murder without as well as within her Majesty's dominions, was rejected by the House of Commons on the second reading, from the idea that it was dictated by France.

POLITICS (Gr. *polis*, city or state), that branch of ethics which has for its subject the proper mode of governing a state, so as to secure its prosperity, peace, and safety, and to attain, as perfectly as possible, the ends of civil society. Among the subjects which political science embraces are the principles on which government is founded, the hands in which the supreme power may be most advantageously placed, the duties and obligation of the governing and governed portions of society, the development and increase of the resources of the state, the protection of the rights and liberties of the citizens, the preservation of their morals, and the defence of the independence of the state against foreign control or conquest. While the philosophy of governing constitutes the science of politics, the art of politics consists in the application of that science to the individual circumstances of particular states. The ancient Greek writers treated politics with reference to an ideal perfect state, which each propounded according to his own speculative views, pointing out the variation of every existing government from his standard. The politics of a country, in common parlance, implies the course of its government, more especially in its relations with foreign powers.

POLIZIANO, ANGELO, whose name is perhaps better known under the Latin form of POLITIANUS, was the son of a doctor of civil law, and was born at Montepulciano in Tuscany, 14th July 1454. The family name was Ambrogini, but P. took his from his native town—in Latin, *Mons Politianus*. He studied Latin at Florence under Cristoforo Landia, Greek under Andronicus of Thessalonica, the Platonic philosophy under Marsilio Ficino, and the Aristotelian under Argyropoulos. He also devoted some attention to Hebrew. P.'s talent for poetry was early developed. When scarcely fifteen years of age, he took the Florentines with surprise by the publication of his famous *Stance* (a poem of 1400 lines) in honor of Giulio de' Medici, who had carried off the palm at a tournament. Lorenzo de' Medici took notice of the brilliant lad, and at once placed him in a condition to continue his studies without any pecuniary harassments, by appointing him tutor to his two sons, and subsequently gave him a residence in his charming villa near Fiesole, where P., who was passionately fond of country life, resumed his studies with fresh ardor.

In 1484, he accompanied the Florentine ambassadors to Rome, and was received in a flattering manner by the pope, at whose request he translated into Latin the Greek historian Herodianus, for which he received 200 golden crowns. He also made Latin versions of the *Enchiridion* of Epictetus, the *Charmides* of Plato, and other works, with such elegance, that Erasmus pronounced him a master in translation. After having filled for some years a chair of Latin literature, he commenced the teaching of Greek. His popularity as a professor was great. Pupils came to study under him from all the great cities of Italy, and even from distant parts of Europe; the principal were Francesco Pucci, Fortiguerra, Maffei de Volaterra, P. Crinitus, Guillaume Grocyon, Thomas Linacre, and Michael Angelo. His copies of Ovid, Statius, Pliny the Younger, Quintilian, &c., and other authors, are still preserved in the different libraries of Italy, and are covered with marginal notes. His copy of the famous *Digest* of Roman law, with an elaborate philological and grammatical commentary, is still preserved in the Laurentian Library at Florence. In 1489 appeared his *Miscellanea*, a collection of critical and other observations on the ancient authors. Towards the close of his life, he entered into orders, and was made canon of the cathedral of Florence. He died 24th September 1494. Among the brilliant scholars of the classical Renaissance, P. occupies a foremost place in virtue of his vigor and originality. His intellect was indeed penetrated by an admiration of the chaste and noble literature of antiquity; but there was nothing servile in his imitations; he reproduced without difficulty—because he was himself a kindred genius—the strength of Tacitus, the elegance of Livy, and the

conciseness of Sallust; his Latin poems, especially his elegies, display the beauty and ardor of his imagination. Among his vernacular pieces may be mentioned his *Canti Carnascialeschi* (Carnival or Merry Ballads), remarkable for their felicity of style, sweetness of pathos, and abundance of imagery. Another proof of his varied poetical power was his *Orfeo*, one of the earliest dramatic compositions produced in Italy. The editions of P.'s separate writings have been numberless. See Serazzi's *Vita di A. Politiano*; N. A. Bonafous *De A. Politiani Vita et Operibus* (Paris, 1845); Tiraboschi's *Storia della Letterat. Italiana*; Greswell's *Memoirs of Politiano*, and Roscoe's *Lives of Lorenzo de Medici and of Leo X.*

POLK, JAMES KNOX, eleventh President of the U. S. of America, was born in Mecklenburg County, North Carolina, November 2, 1795. His ancestors, who bore the name of Pollock, emigrated from the north of Ireland early in the 18th century. Though his father was a farmer in moderate circumstances, he was educated in the university of North Carolina, and studied law with Felix Grundy of Tennessee, an eminent lawyer and statesman. Admitted to the bar in 1820, he was three years after elected a member of the legislature of Tennessee, and soon after, to the Federal Congress, by the Democratic party. In 1836, he was chosen Speaker of the House of Representatives, a position he filled during five sessions with firmness and ability. After serving fourteen years in Congress, he was, in 1839, elected governor of Tennessee; and in 1844, unexpectedly nominated, as a compromise candidate, for the presidency, against Henry Clay, and elected. During his term, the Oregon boundary was settled by a compromise offered by England, though the party cry which helped to elect him was a claim for the entire territory to 54° 40' N. lat. The annexation of Texas caused, in 1846, a war with Mexico: 50,000 volunteers, added to the small regular force, sufficed to take the capital (September 14, 1847), and enabled the government to dictate terms of peace, by which it acquired California and New Mexico. Having pledged himself to a single term of office, Mr. P. refused a renomination, and retired to his home in Nashville, Tennessee, where he died three months afterwards, June 15, 1849. Mr. P. was a man of respectable abilities, and of a solid, firm, honest, and religious character. He was devoted to the principles of the Democratic party of Jefferson and Jackson to state rights, a revenue tariff, independent treasury, and strict construction of the constitution.

POL'KA, a species of dance, of Polish or Hungarian origin, the music to which is in $\frac{3}{4}$ time, and has the rhythmical peculiarity of being accented on the third quaver of the measure. It was introduced as a fashionable dance into Western Europe about 1841.

POLL-ACT, a sanguinary act, passed at Trim in Ireland, by the Junto of the Pale, in 1465, under the Earl of Desmond, deputy. It ordained 'that it shall be lawful to all manner of men that find any theeves robbing by day or night, or going or coming to rob or steal, or any persons going or coming, having no faithful man of good name and fame in their company in English apparel, that it shall be lawful to take and kill those, and to cut off their heads, without any impeachment, of our sovereign lord the king. And of any head so cut off in the county of Meath, that the cutter and his ayders there to him cause the saed head so cut off to be brought to the portreffe to put it upon a stake or spear, upon the Castle of Trim, and that the saed portreffe shall testify the bringing of the same to him. And that it shall be lawful for the saed bringer of the saed head to distrain and levy by his hand (as his reward) of every man having one ploughland in the barony, two pence; and of every man having half a ploughland, one penny; and of every man having an house and goods, value forty shillings, one penny; and of every cottier having one house and smoak, one half-penny.' Much slaughter is said to have been committed under this remarkable act.

POLL-TAX. See CAPITATION.

POLLACK (*Merlangus pollachius*), a fish of the family *Gadidae*, of the same genus with the Whiting and Coal-fish. It is common on the coasts of all parts of Britain; and in Scotland and some parts of Ireland, it is called *Lythe*. It is a very playful fish, often gambolling on the surface of the water. It attains about the same size as the coal-fish. It has three dorsal fins; the body is of a loughish shape; the lower jaw is much longer than the upper; the tail is slightly forked. The flesh is reckoned superior to that of the coal-fish. Young pollacks are sometimes sold as whittings, to which, however, they are not nearly equal. No fish more readily rises to the artificial fly, and in this way great numbers are caught on the British coasts. The fly is merely a bit of white feather tied to a common bait-hook. Worsted is sometimes used instead of the feather; and flies of different colors are sometimes used together, with great success. No reel is employed, and any stick is good enough for a rod; a few yards of string make a sufficient line.

PO'LLAN (*Coregonus Pollan*; see COREGONUS), a fresh-water fish of the family *Salmonidae*, a native of lakes in Ireland. It is particularly abundant in Lough Neagh, where it is often seen in large shoals, which issue from the deep waters, and haunt the shore from spring to autumn, when great numbers are taken by nets, and sold in the neighboring country. The P. is from 10 to 12 inches in length; it resembles the Gwyniad, but has not the snout produced like that fish; and there are differences in the size and position of the fins. It is very like *Coregonus albus*, a species found in the most northern parts of Norway. The spawn of the P. is deposited in November and December on the rocky or stony parts of the bottom of the lake which it inhabits. It is a well-flavored fish. The cry of 'Fresh Pollan' is even more common in Belfast during summer than that of 'Fresh Herring.'

PO'LLARDING (to poll, to cut off, or shave the head) is the cutting off of the whole crown of a tree, leaving it to send out new branches from the top of the stem. Trees thus treated are called *pollards*. The new branches are never equal in magnitude to the original branches of the tree, although often more numerous, and when pollarding is often repeated, the scars and stumps form a thick ring at the top of the stem, from which many small branches spring. Pollards are not beautiful; but pollarding is practised with advantage in districts where fuel is scarce, the

Pollard Oak.

branches being cut off in order to be used for fuel, and the operation repeated every third or fourth year. It is much more prevalent in many parts of Europe than in any part of Britain, and in Britain is almost confined to those districts of England which are furthest from coal. Willows, Poplars, Alders, Eims, Oaks, and Limes are the trees most frequently pollarded, and in some parts of Europe the White Mulberry. The trees of most rapid growth are preferred where fuel is the object; and willows, poplars, and alders are planted along water-courses, and in rows in moist meadows and bogs. Oaks are sometimes pollarded chiefly for the sake of the bark of their branches, and the whole treatment very much resembles that of copse-wood. In some parts of Germany, landscapes may be seen of open country with many scattered oak and elm pollards, presenting a very peculiar appearance.

PO'LLEN. See STAMEN and FECUNDATION.

POLLE'NZA, a well-built town in the northern part of the island of Majorca, about 2 miles west of the Bay of Pollenza, and 28 north-west of Palma. It has a Jesuits' college and some manufactures of blank woollen cloth. Pop. about 7500.

PO'LLIO, C. ASINIUS, a politician, soldier, and author of considerable merit, and still more considerable reputation, was born in Rome 76 B.C., but belonged to a family of Marrucian descent. His first ambition was to be an orator, and in his youth he seized every opportunity of hearing such men as Hortensius and Cicero. When civil war broke out between Cæsar and Pompey, P. sided with the former, was present at the crossing of the Rubicon, and accompanied the great general in his rapid triumphal march through Italy. He joined Cæsar in his expedition to Greece against Pompey, and took part in the decisive battle of Pharsalia, 48 B.C. At the time of Cæsar's assassination (15th March, 44 B.C.), P. was governor of Hispania Ulterior (Further Spain), and carrying on the war against Sextus Pompey. In the subsequent struggles, he sided with the triumvirate (Antony, Lepidus, and Octavian) against the oligarchic senate; and on the triumph of the former, was appointed administrator of Transpadane Gaul, in which capacity he saved the property of the poet Virgil at

Mantua from confiscation. After Antony and Octavian had quarrelled, it was P. who effected their temporary reconciliation at Brundisium, 40 B.C.; next year he conducted a successful campaign against the Parthini, a people of Illyria, and in consequence, obtained a triumph. After this event, however, he withdrew altogether from political life. He lived 18 years after the Emperor Augustus, dying at his Tusculan villa, 4 A.D., in the 80th year of his age. Besides having a reputation for oratory, P. was celebrated as a historian, poet, and critic; and there seems little reason to doubt that he was an author the loss of whose writings is to be regretted. His literary and political criticism of his contemporaries, in particular, appears to have been valuable. He also claims remembrance as a distinguished patron of men of letters, such as Catullus, Horace, Virgil, and as the founder of the first public library at Rome.

POLLNITZ, KARL LUDWIG VON, noted as a writer of memoirs of his time, was born near Cologne in 1692. He was equally remarkable for his talents and want of principle; and while his father's position as minister of state to the Elector of Brandenburg gave him access to court-circles, his extravagance and eccentricity, coupled with his vagabond habits, often reduced him to the greatest poverty. But after wandering all over Europe, taking service in the church in Austria, and in the army in Spain, he finally attracted the favorable notice of Frederick the Great, who appointed him his reader, and made him director of the theater at Berlin. After having twice changed from Catholicism, to Calvinism, he proclaimed himself a member of the church of Rome shortly before his death, which occurred in 1775. Among the numerous memoirs, either written by or ascribed to him, the following were the most popular in their day, and the most applauded for the powers of observation and the wit which they exhibited: *Lettres et Mém., et la Relation de ses premiers Voyages* (Amst. 1735); *Etat abrégé de Saxe sous Auguste III.* (Frankf. 1734); *Hist. secrète de la Duchesse d'Hanovre, épouse de George I.* (Lond. 1732). After his death, Brunn brought out P.'s *Mémoires pour servir à l'Histoire des quatre derniers Souverains de la Maison de Brandenburg* (2 tomes, Berl. 1792).

POLLOCKSHAW'S, a municipal borough in the county of Renfrew, Scotland, is situated on the banks of the White Cart, about 2½ miles south-west of Glasgow. The name is derived from the estate of Nether-Pollock, on which the town stands, and from the Scotch word 'shaw,' which means a 'grove' or 'plantation.' P. is entirely a manufacturing town; cotton-spinning, calico-printing, silk-weaving, bleaching, iron-founding, and fancy dyeing, are extensively carried on. Pop. (1881) 9333.

POLLOCK, ROBERT, a Scottish poet, was born in 1799 at Muirhouse, in the parish of Eaglesham, in the county of Renfrew. After receiving the ordinary course of instruction in country schools, he was sent to the university of Glasgow, and on the completion of his curriculum in arts, he entered the Divinity Hall of the Secession Church, where he studied five years. In 1827, he was licensed to preach. By this time he had written the *Course of Time*, and its composition, together with the ardor with which he pursued his studies brought on consumption. The poem was published by Mr. Blackwood in the same year in which the author received license. It was highly praised, but the voice of praise fell on a dying ear. In his critical state, his medical attendants recommended residence for a time in Italy, and in compliance with their advice, he set out, accompanied by his sister. On his arrival in London, his symptoms became suddenly worse, and unable to prosecute his journey, he went to reside at Shirley Common, near Southampton, where he died on the 17th September 1827. He was interred in the churchyard at Millbrook, and over his grave an obelisk has been erected.

The *Course of Time* has run through more than twenty editions, and is extremely popular in Scotland. It is a work of genius, but curiously unequal in merit. It contains eloquent and spirited passages, but considerable portions of it read like a dull sermon turned into blank verse. The writer drew his inspiration from nature, from Milton, and the Shorter Catechism—from the last, perhaps, most of all. His Memoir, written by a brother, was published in 1843. P. also wrote *Tales of the Covenanters*, which were published anonymously.

POLO, MARCO, the celebrated traveler, was born of a noble family of Dalmatian origin, at Venice, about 1250. His father, Nicolo Polo, and his uncle, Matteo Polo, both eminent merchants, had, previous to his birth, set out on a mercantile expedition visiting Constantinople, Soldaya or Sondach (on the Euxine), and Bulgar (on the Volga), the capital of Barkai, the Khan of Keptchak. Thence they traveled round the north side of the Caspian Sea to Bokhara, where they remained three years, studying the Mongol language and trading; but in 1261, some ambassadors from the Perso-Mogul khan to Kúblai (q. v.), the Grand Khan of the Mongols, happening to pass through Bokhara, the brothers Polo resolved to accompany them to Kementu, the summer residence of the Khagan. They were well received by Kúblai, who

was very inquisitive concerning the peoples and mode of government in Europe, and commissioned them to act as his envoys to the pope, bearing a written request for 100 Europeans, well learned in the sciences and arts, to act as instructors to the Mongols. They reached Venice in 1269; but finding it impossible to discharge the mission with which they had been intrusted, they set out on their return in 1271, taking with them young Marco, and arrived again at the court of Kúblai Khan in 1275. Their second reception was still more honorable than the first, and the Khagan took special notice of Marco, from the rapidity with which he learned the customs and language of the Mongols. His wisdom and the nobility of his demeanor also recommended him as a fit envoy to the various neighboring rulers; and during his residence at their several courts, P. was in the habit of closely observing the manners and customs of the country, and delivering on his return a detailed report to the Khagan. These reports were the groundwork of the book which informs us regarding the state of Central and Eastern Asia in the end of the 13th century.

P.'s first mission was to the court of Annam or Tonquin (1277), and during his residence there, he acquired much information, both from his own observation and from report, concerning Tibet, Yunnan, Bengal, Mien (or Pegu), and the south of China; he was next employed to aid in making an inventory of the archives belonging to the court of the Song dynasty; and soon afterwards was appointed governor of the town of Yang-tchow, in the province of Kiang-si, in Eastern China, a post he held for three years. He also accompanied a Mongol army to the attack of the kingdom of Pegu; and closed the list of services rendered to Kúblai by accepting the embassy to Tsiampa, the south part of Cochinchina. Having thus passed 17 years in the service of the Mongol khan, and visited the chief countries and cities of Eastern Asia, traveling through kingdoms (as China) which no European had ever seen before, and acquiring much knowledge of other kingdoms (as Japan, called by P. *Zipangu*), the existence of which was not even suspected, he succeeded in obtaining permission to join the escort of a Mongol princess, who was traveling to the court of Persia. The three Polos accordingly set out in 1291, traveling through China, and thence, by sailing through the Chinese Sea and Indian Ocean, finally arrived at Teheran, where they stayed for some time; but learning that Kúblai Khan was now dead, they continued their journey, and arrived at Venice in 1295, bringing with them much wealth and many precious objects, the fruits of their trading. Marco, in the following year, fought his own galley in the great battle off Curzola, in which the Venetians, under Dandolo, were defeated by the Genoese under Doria, and was taken prisoner and immured in a dungeon at Genoa. Here he dictated, with the aid of the memoranda he had made during his travels, an account of his journey through the East, which was subsequently revised with care.

After his liberation he returned to Venice, where he was appointed member of the Grand Council, and died in 1323, eleven years after his father. His work is variously entitled, but the best edition is *Il Milione di Messer Marco Polo Veneziano*, edited by Count Baldelli (Florence, 4 vols. 4to, 1827), and accompanied with a map, notes, and illustrations. P.'s narrative created an immense sensation among the learned public, and many did not hesitate to affirm that it was a pure fiction; but the Catholic missionaries and subsequent Venetian travelers into these remote regions, verified many of P.'s statements, and then came a reaction of public opinion; P.'s wonderful minuteness, extensive research, and accuracy, being the theme of universal admiration. His work was of inestimable value as a stimulant and guide in geographical research; it encouraged the Portuguese to find the way to Hindustan round the Cape of Good Hope; and it roused the passion for discovery in the breast of Columbus, thus leading to the two greatest of modern geographical discoveries. The first edition of P.'s 'Voyages' was published by Ramusio in his *Raccolta di Navigazioni e Viaggi* (Venice, 1550—1559). English translations have been published in Edinburgh (1844), and in London (1854 and 1871—1875). There is also a German one by Burck, with notes by Neumann (1846).

POLO, an equestrian game recently introduced from India into England, where not a few P. clubs have been founded. The game was first taken up by British cavalry officers when stationed at Lahore in the Punjab; and in England it is still practised chiefly by officers. P. may be familiarly described as hockey on horseback. The ground is three or four hundred yards long, and nearly as wide; the goals are each marked by two posts eight feet apart. Each player, mounted on his pony—for in England ponies are usually employed—holds in his hand a stout stick, having a curved hook at the lower end. The stick is not long enough to touch a ball on the ground without the rider's stooping somewhat; and he must be prepared to stoop to right or left with equal readiness, and to drive the ball backward, forward, or sidewise. The ball is dropped on the ground midway between the goals; then two sets of riders (generally about five on each

side) gallop forward, each endeavoring, by means of repeated strokes, to drive the ball through the enemy's goal. As a safeguard against kicks during the scrimmage, the legs of the ponies are thickly bandaged. P. is admittedly an exciting amusement, and is also splendid training for a horseman.

POLO'TSK, a town of West Russia, in the government of Vitebsk, on the banks of the Duna, where that river is joined by the Polota. It was founded in the 9th c., is the seat of a bishop of the Greek United Church, and has several churches, besides a convent and a school for the nobility. Here, in 1812, the Russian general, Wittgenstein, defeated the French under Oudinot and Sire. Pop. (1867) 11,418.

POLTA'VA, chief town of the government of the same name, is situated on the right bank of the Worskia, a tributary of the Dnieper, about 934 m. S.S.E. of St. Petersburg. Pop. (1867) 31,852. P. has few manufactures, and its trade displays activity only during the annual fairs, of which there are four. The most important is called the Illinsky, which lasts about a month. At these fairs, merchandize is exposed for sale worth £4,000,000. The principal articles of traffic are cloths, woollen tissues, colonial productions, fur, wool, horses, and agricultural produce and implements. P. is famous as the scene of Charles XII.'s defeat by Peter the Great in 1709, and a monument commemorating the victory of the czar stands in the principal square; while three miles from the town a mound surmounted by a cross, still known as the 'Swedish Tomb,' marks the battlefield. P. has a cathedral, numerous churches, and a school for cadets.

POLTAVA, a government of Little Russia, between the governments of Kiev on the west and Kharkov on the east. Area, 19,071 sq. m.; pop. (1870) 2,102,614. The surface is flat, with a gradual slope south-west to the banks of the Dnieper, which forms the southern boundary, and into which the chief rivers—the Sula, Psiol, and Worskia—flow. The government does not abound in wood, but possesses rich and extensive pastures. The soil is for the most part clay and fertile vegetable mould, and the climate is healthy. Agriculture and cattle-breeding are the staple occupations. Many of the peasantry are employed with their oxen in bringing salt from the lakes of the Crimea, and fish from the Don. The manufactures are not numerous nor important. Commerce is chiefly in the hands of Jews, and is mostly transacted at the fairs, the most important of which are those of Poltava and Romny.

PÖLTEN, Str. is a fortified town of Lower Austria, 35 m. W. of Vienna. It is the seat of a cathedral, and has manufactures of cotton, paper, glass, and stoneware goods. Pop. (1869) 7779.

POLYA'NDRY, or **POLYANDRIA**, that form of polygamy which permits a woman to have several husbands. See **MARRIAGE**. The hot-bed of polyandry is Tibet. There a wife commonly is the wife of a whole family of brothers—the elder brother being chief husband. In the Himalayan and sub-Himalayan regions adjoining and under the influence of Tibet, it is of frequent occurrence in the same form, as in the valley of Kashmir, in Ladak, among the Koech, among the Telingese. Further south in India, we find polyandry among the Todas of the Nilgherry Hills, the Coorgs of Mysore, and the Nayars of Malabar. We find it again off the Indian coast in Ceylon; and going eastward, strike on it as an ancient though now almost superseded custom in New Zealand, and in one or two of the Pacific islands. Going northward, we meet it again in the Aleutian Islands; and taking the continent to the west and north of the Aleutians, it is found among the Koryaks, to the north of the Okhotsk Sea. Crossing the Russian empire to the west side, we meet it among the Saporogian Cossacks; and thus have traced it at points half round the globe. This is not all, however. It is found in several parts of Africa; and it occurs again in many parts of America among the red men. We have the authority of Humboldt for its prevalence among the tribes on the Orinoco, and in the same form as in Tibet. 'Among the Avaroes and the Maypures,' he says, 'brothers have often but one wife.' Humboldt also vouches for its former prevalence in Lancerota, one of the Canary Islands.

Thus, polyandry is a phenomenon of human life independent of race and country.—See Latham's *Descriptive Ethnology* (1859), vol. i. pp. 24, 28; vol. ii. pp. 398, 406, and 462; Humboldt's *Personal Narrative*, William's translation, 1819, vol. v. part 2, p. 549; and chap. i. vol. i. p. 84; Hamilton's *New Account of the East Indies* (Edin. 1727), vol. i. pp. 274 and 308; Reade's *Savage Africa*, p. 43; Erman's *Travels in Siberia*, vol. ii. p. 531; *Marriage Ceremonies*, by Seigneur Gaya (translation), 2d edition (Lond. 1698) pp. 70 and 96; Emerson-Tennent's *Ceylon*, 3d edition (1859), vol. ii. p. 429; Grey's *Polynesian Mythology*, 1855, p. 81; *A Summer Ramble in the Himalayas* (1860); Vigne's *Kashmir*; *Journ. Asi. Soc. Bengal*, vol. ix.; *Asiat. Resch.*, vol. v.; also McLennan's *Primitive Marriage* 1865; and Herbert Spencer's *Principles of Sociology* (1876).

From ancient history we learn that the area over which poly-

andry at one time existed was even more extended; while in certain cantons of Media, according to Strabo (lib. ii. p. 798, and see Goguet, vol. iii. book vi. c. i.) polygyny was authorized by express law, which ordained every inhabitant to maintain at least seven wives; in other cantons, precisely the opposite rule prevailed; a woman was allowed to have many husbands, and they looked with contempt on those who had less than five. Caesar informs us that in his time polyandry of the Tibetan type prevailed among the Britons (*De Bello Gallico*, lib. v. c. xiv.). We find direct evidence of its existence among the Picts in the Irish Nennius App. ii., not to mention the traces of it remaining in the Pictish laws of succession. Indeed, to pass over communities in which something like promiscuity of intercourse between the sexes is said to have prevailed—such as the Massageteæ, Agathyrst, and the ancient Spartans—we find several among which polyandry, or a modified promiscuity, must have been the rule.

Assuming that the legal obligation laid on younger brothers in their turn to marry the wives of their deceased elder brother, is a relic of polyandry of the Tibetan type, then we must hold that polyandry prevailed at one time throughout India (*Institutes of Menu*, chap. iii. s. 173, and chap. ix. ss. 57, 58), among the ancient Hebrews (Deut. xxv. verses 5–11); in Siam, Burmah, in Syria among the Ostiaks, the But (Bodo), the Kasia, and the Puharies of Gurlwal. Traces of it indeed remained in the time of Tacitus among the Germans (Tac. *Germ.*, xx., Latham's edition, p. 67 and seq.). In short, polyandry may be regarded as one of the transitional forms in the advance from a state of promiscuity, on the assumption that pure promiscuity ever existed. Of the origin of this peculiar institution, our space forbids us to write; but we believe it to be connected with the want of balance between the numbers of the sexes, due to the practice of female infanticide, which is its almost invariable accompaniment. Tribes of warriors, wholly devoted to a military life, find women an incumbrance rather than a solace; and from this cause, and probably from the difficulties of subsistence, formed the practice of killing their female children, sparing them only when they were the first-born. The disparity of the sexes would lead to polyandry, and once instituted, the custom would in many cases continue to exist after the habits and necessities which produced it disappeared. In several places, as in Ladak, where polyandry prevails, the sexes are now either equally balanced, or the female sex predominates. In these cases, polygyny and polyandry are commonly found existing side by side. The subject is one which demands, and as yet has not received full investigation.

POLYA'NTHUS (Gr. many-flowered), a kind of Primrose (q. v.), much prized and cultivated by florists. It is generally believed to be a variety of the Common Primrose (*Primula vulgaris*),

Polyanthus.

produced by cultivation, in which an umbel of numerous flowers is supported on a common scape (leafless flower-stem), instead of each flower rising on its own stalk from the crown of the root; a modification to which a tendency often appears in the wild plant itself. Thus, in its habit it somewhat resembles the cowslip and oxlip, whilst in the size of its flowers it is more like the common primrose; but instead of the pale uniformity of the wild plant, it exhibits great variety of delicate and beautiful colors. The sub-varieties are innumerable, new ones being continually produced from seed, and of short duration. The seed is sown about mid-summer, and flowers may be expected in abundance next year, if the young plants are properly planted out. A rich free soil is most suitable. The P. loves shade and moisture more than its congener, the auricula. It is very hardy, and seldom suffers from the most severe winters. Fine kinds are preserved for a time by dividing the root. The cultivation of the P. is prosecuted with particular assiduity and success in England.

POLYA'NTHUS NARCI'SSUS. See **NARCISSUS**.

POLYATO'MIC ALCOHOLS. The term *Alcohol*, originally limited to one substance—viz., spirit of wine, or hydrated oxide of ethyl, has begun to be applied to a considerable number of organic compounds, many of which, in their external characters, bear little resemblance to common alcohol. Most of them are fluid and volatile, some of them are combustible, and all of them are composed of carbon, hydrogen, and oxygen, behave in a precisely similar manner towards the same decomposing agents, and are perfectly neutral to test-paper.

Every alcohol, when acted on by oxidizing agents, loses two equivalents of hydrogen, and is converted into an *Aldehyde*; and by the prolonged action of the oxidizing agent, the aldehyde takes up two equivalents of oxygen, and is converted into a *special acid*. Moreover, all alcohols, by the abstraction of the elements of water, yield ethers. Hence, every alcohol has its own ether, aldehyde, and special acid; the aldehydes of the alcohols termed polyatomic have, however, not been formed.

According to the theory of organic radicals, the alcohols are hydrated oxides of an alcohol radical. Thus, common alcohol, or spirit of wine, is the hydrated oxide of the radical ethyl (C_2H_5), and is represented by the formula $C_2H_5O.HO$; similarly, wood-spirit is the hydrated oxide of the radical methyl (C_2H_3), and is represented by the formula $C_2H_3O.HO$. According to the theory of chemical types (see TYPES, CHEMICAL), the alcohols are divided into *monatomic* and *polyatomic*. A molecule of water consists of two atoms of that substance, and is therefore represented

by the formula H_2O_2 , which may be arranged in the form $\begin{matrix} H \\ | \\ H \end{matrix} \{ O_2$.

If half the hydrogen in this typical formula be replaced by an organic radical, such, for example, as C_2H_5 , C_2H_3 , C_2H_2 , C_2H , or C_2H_{n-1} (n being even in all these cases), we obtain what is termed a *monatomic alcohol*, one equivalent of hydrogen being here replaced. Besides the primary water-type represented by one molecule of water, there are derived or secondary and tertiary types, represented by two and by three molecules of water,

and expressed in the forms $\begin{matrix} H_2 \\ | \\ H_2 \end{matrix} \{ O_2$ and $\begin{matrix} H_3 \\ | \\ H_3 \end{matrix} \{ O_2$. If half the hy-

drogen in $\begin{matrix} H_2 \\ | \\ H_2 \end{matrix} \{ O_2$ be replaced by an organic radical, we obtain

an alcohol said to be *diatomic*, in consequence of its being formed by the replacement of two equivalents of hydrogen. Similarly,

if half the hydrogen in $\begin{matrix} H_3 \\ | \\ H_3 \end{matrix} \{ O_2$ be replaced by an organic radical,

we obtain a *triatomic alcohol*. The term *polyatomic* is applied to all alcohols which are not monatomic.

POLYBASIC ACIDS. Most of the inorganic acids combine with bases in such a manner that one atom of the acid is united with one atom of a metallic oxide to form a neutral salt. Nitric acid may be taken as an illustration of the acids possessing this property, and which may therefore be called *monobasic*. In other cases, as, for example, that of pyrophosphoric acid (see PHOSPHORUS), one atom of acid possesses the property of combining with two atoms of base; such acids are termed *dibasic* or *dibasic*. There are strong grounds for believing that sulphuric acid is *dibasic*, in which case its formula would require to be doubled, and to be written $2HO.S_2O_6$. Common phosphoric and arsenic acids are examples of a third class of acids in which one atom combines with three atoms of base, and which are therefore termed *tribasic*. Whether any polybasic acids beyond tribasic acids exist, is uncertain, but it is probable that silicic acid is a *tetrabasic acid*.

Amongst the organic acids, a similar relation takes place, acetic, succinic, and citric acids affording examples of the *monobasic*, *dibasic*, and *tribasic* class.

The following are the most important general differences shown by acids of different degrees of basicity.

1. Each *monobasic acid* can form but one ether, which is neutral.
2. A *Monobasic acid* cannot form a stable, well-defined acid salt, or a salt with two or more metallic bases.

1. Each *dibasic acid* can form two ethers, one neutral, and the other acid. 2. *Dibasic acid* can form with each metallic base a neutral salt, and an acid salt. They can also form double salts containing two metallic bases.

1. Each *tribasic acid* can form three ethers, one neutral, and two acid. 2. *Tribasic acids* can form three salts with the same metallic base, two of them acid, and one neutral.

Many attempts have been made to account for the polybasic or monobasic character of an acid, from its composition. According to the Kekulé (*Lehrbuch der organisch. Chemie*, vol. 1, p. 210—219), the basicity depends not, as was formerly supposed, on the molecular constitution of the acid, but upon the amount of oxygen contained in its radical. For further details on this subject, the reader is referred to the article ACIDS in Watt's *Dictionary of Chemistry*, vol. 1, 1863.

POLYBIUS, the Greek historian, was born about 204 B.C. in Megalopolis, a town of Arcadia. From Lycortas, his father, who was among the leading men of the Achæan League, he received valuable instruction in the science of politics and in the art of war. In 181, he would have visited Egypt in the capacity of ambassador, but the project of sending an embassy to that country was given up. His engaging in public affairs probably dates from this period; and he rapidly gained the confidence of his countrymen. He was one of the 1000 noble and influential Achæans, who, after the conquest of Macedonia in 168, were sent to Rome on the summons of the commissioners from that city to answer the charge of having failed to assist the Romans against King Perseus. On their arrival in Italy in 167, they were not put upon their trial, but were distributed among the towns of Epirus. Owing, perhaps, to his having formed the friendship of Emilius Paulus, or of his sons Fabius and Scipio, he was more fortunately allocated than others of his countrymen. His residence was fixed at Rome and in the house of Paulus. Scipio, then about 18 years of age, became strongly attached to P., made him his companion in all his military expeditions, and profited greatly by his knowledge and experience. P. in his turn derived much advantage from the protection and friendship of Scipio, who gave him access to public documents, and aided him in the collection of materials for his great historical work. In 151, the surviving Achæan exiles were permitted by the Roman senate to return to Greece, and among them was P., who arrived in Peloponnesus after a residence of 17 years in Italy. He soon, however, rejoined Scipio, followed him in his African campaign, and was present at the destruction of Carthage in 146. But the outbreak of war between the Achæans and Romans summoned him again to Greece, where he arrived soon after the taking of Corinth.

All his influence was now exerted to procure from the conquerors favorable terms for the vanquished, and so grateful were his countrymen for his services in their behalf, that they erected statues in his honor at Megalopolis (his native town), Mantinea, Pallantium, Tegea, and other places. It must have been about this time that P. undertook the writing of his great historical work, the materials of which he had so long been collecting. We cannot now fix with accuracy at what period of his life he visited in foreign countries the places which he had to describe in his history. We know from himself that at one time, probably while accompanying Scipio, he undertook long and laborious journeys into Africa, Spain, Gaul, and even as far as the shores of the Atlantic, in order to add to the scanty knowledge previously existing with regard to these regions. In the latter period of his life, he traveled in Egypt; and about twelve years before his death, he probably accompanied Scipio to Spain, where he witnessed the fall of Numantia. He died about 122 B.C., in his 82d year, in consequence of a fall from his horse.

As a historian, P. occupies a high rank. His work, which began where that of Aratus broke off, includes the period between 220 and 146 B.C., the year when Corinth fell, and, with it, the independence of Greece. Of the two parts into which it was divided, the first embraced a period of 53 years, commencing with the Second Punic War and the Social War in Greece, and concluding with the subjugation of the kingdom of Macedonia in 168. This, the chief portion of his history, was designed to show how, in the short space of 53 years, the greater part of the world had been conquered by the Romans; and in order that his countrymen might have a better knowledge than they possessed of the rise of that people, he gives a sketch of the history of Rome from its capture by the Gauls to the outbreak of the Second Punic War. This occupies the first two books, and may be regarded as an introduction to the work.

The second part embraces the period from the fall of the Macedonian kingdom, in 168, to the taking of Corinth in 146. This part is to be viewed as supplementary to the first, and seems to have brought down the history of the conquest of Greece to its completion in the 39th book, while the 40th and last probably contained a chronological summary of the entire work. The style of P. is not his most striking feature, and he incurred the censure of later Greek critics for his negligence in the choice of words and in the structure of his sentences. His great merits are the care with which he collected his materials, his strong love of truth, and the sound judgment, which was materially assisted by his familiarity with political and military life. His tone is too didactic in general, and although his readers are prepared for this by his calling his work not a *Historia*, but a *Pragmateia*, still the continuity of the narrative is too often interrupted by digressions, sometimes interesting and valuable in themselves, but fatal to artistic effect. Much the greater part of his work has perished. Of the 40 books, we possess only five entire; and of the rest, merely fragments or extracts. Some of these latter, however—such as the account of the Roman army—are of considerable length and value, and four separate collections of them have been added from time to time to the remains of the work. The first of these, discovered soon after the revival of learning, in a

MS. of Corfu, gives us the greater part of the 6th book, and portions of the remaining 11. The second consists of extracts made in the 10th c., entitled *Excerpta de Legationibus*, and published at Antwerp by Ursinus in 1582. The third, entitled *Excerpta de Virtutibus et Vitiis*, was published in 1634 by Valesius. The fourth, entitled *Excerpta de Sententiis*, was discovered by Cardinal Mai in the Vatican, and published by him at Rome in 1827. The history of P. was very closely followed by Livy after the period of the Second Punic War, and by Cicero in his account of the Roman constitution in his treatise *De Republica*.—The best annotated edition of P. is Schweighäuser's (Leip. 1789). The best editions of the text, including that of the Vatican fragments, are those of Bekker (Ber. 1844) and L. Dindorf (1866).

POLYCARP, Bishop of Smyrna, and one of the most illustrious of the early Christian martyrs, was born in the latter part of the 1st c. A.D., but neither the date nor the place of his birth is known. He was, however (according to a legendary fragment ascribed to an unknown Pionius), brought up at Smyrna, where his pupil, Irenæus, states that P. was taught the doctrines of Christianity by the apostles, particularly by John, with whom he had 'familiar intercourse.' The testimony of Irenæus on this point is of immense value, as it furnishes the chief historical link uniting the apostolic age—that age which is reflected in the later parts of the New Testament—with the rising church of the 2d century. The passage occurs in an expository epistle to a Roman heretic, Florinus, and is preserved by Eusebius (*Hist. Eccl.* chap. xx.). 'I can tell also the very place where the blessed Polycarp was accustomed to sit and discourse; and also his entrances, his walks, the complexion of his life, and the form of his body, and his conversations with the people, and his familiar intercourse with John, as he was accustomed to tell, as also his familiarity with those that had seen the Lord. Also concerning his miracles, his doctrine, all these were told by Polycarp, in consistency with the Holy Scriptures, as he had received them from the eye-witnesses of the doctrine of salvation.' The fragment of Pionius (to which reference has already been made) informs us that P., when only a little child, was adopted by a rich Christian lady named Callisto, who left him heir to all her wealth; in consequence of which he was enabled to gratify his love of works of beneficence and charity. We are, however, utterly without the means of determining what truth (if any) there is in the narrative of Pionius, and can only feel certain that in some way or other he had distinguished himself at a comparatively early period, for before the death of the Apostle John (i. e., at the latest, before 104 A.D.), he was ordained Bishop of Smyrna (according to Tertullian and Jerome) by John himself; according to Irenæus, by 'the apostles;' and according to Pionius by 'the bishops of the neighboring churches'—statements which are quite reconcilable with each other. P. was in the exercise of his episcopal functions when Ignatius of Antioch passed through Smyrna on his road to Rome (107—116 A.D.); and we are told that the two pupils of St. John, who had probably known one another in earlier years, had much delightful Christian converse.

Almost half a century afterwards, P. himself visited Rome, when Anicetus was bishop there (157—168 A.D.), and had a friendly conference with his brother on the subject of the proper time to hold Easter. They could not agree—but they agreed to differ. His martyrdom, which is related at great length and in a touching manner by Eusebius (*Hist. Eccl.* chap. xiv.), took place probably in 166 A.D., during the persecution under the emperors Marcus Aurelius and Lucius Verus. When asked, or rather entreated 'to revile Christ' by the proconsul Statius Quadratus, who, being deeply impressed with the venerable appearance of the aged bishop, wished if possible to save his life, P. replied: 'Eighty-and six years have I served him, and He never did me wrong; and how can I now blaspheme my King that has saved me.' P. was burned alive. In such profound reverence was he held by his fellow-Christians, for his almost perfect graces of character, that the Jews (who had been conspicuously zealous in collecting 'wood and straw from the shops and baths' to burn him) instigated the proconsul not to give up the corpse of the martyr to his co-religionists, 'lest, abandoning him that was crucified, they should begin to worship this one.' More convincing evidence of a saintly character has never been adduced.

P. wrote several *Epistolæ*, of which only one has been preserved, the *Epistola ad Philippenses*, valuable for its numerous quotations from the New Testament—especially from the writings of Paul and Peter. It is, however, doubtful whether this epistle is really by P. In the most recent edition of the Apostolic Fathers (*Patrum Apostolicorum Opera*, Leipsig, 1877), Prof. Zahn defends its genuineness. There are English versions by Cave, Clementson, and Wake.

POLYCHROME PRINTING, the art of printing in one or more colors at the same time. Although several attempts had been previously made to carry out this process, Congreve, in 1820, was the first to do it successfully with metal plates. Sir William Congreve had seen Applegath's poly-chromatic block-

printing press, by which very rude-colored pictures were produced, and he conceived the idea of improving upon it, and doing it with metal. His plan is extremely simple, though requiring great nicety in carrying it out. First, the picture is outlined upon a metal-plate; and supposing it intended to have two colors, then the details of only the chief color are completed upon it, and all the parts for the other color are cut out; and into those parts other plates are fitted, like the portions of a child's puzzle-map, but with very great exactness; and upon these the engraving for the parts of the second color are completed. When these are done, a thickness of type-metal is attached to the back of these interior pieces, so that they can be held separately, and pushed forwards or drawn backwards at pleasure. Then they are so adjusted to the machinery of the press, that they are withdrawn when the first color-roller passes over the surface of the main plate, and are pushed forward beyond the face of the main plate, so as to receive the color of the second roller, which then passes over them without touching the first or main plate. Having received their colored ink, the secondary plates are again moved back to a perfect level with the other, so as to form an entire plate, carrying two colors, which are thus, in the ordinary way, imprinted on the paper. Since Sir William Congreve's patent, very many improvements have been made, the principle, however, remaining the same, and it has now a very wide application.

POLYCOTYLE/DONOUS PLANTS, those plants of which the embryo has more than two seed-lobes or cotyledons. See COTYLEDON and DICOTYLEDONOUS PLANTS. In some of the *Conifera* in particular, there are numerous cotyledons; the genus *Pinus* has from three to twelve. These cotyledons are placed in a whorl, and have the gemmule of the embryo in the midst of them. Polycotyledonous plants do not form a separate division of the vegetable kingdom, but are ranked with dicotyledonous plants; for plants with two, and plants with more cotyledons, are found not only in the same natural order, but in the same genus.

POLYCRATÉS, 'tyrant' of Samos, is a well-known name in ancient Greek history. He was born in the first part of the 6th c. B.C., but nothing is known of him until the time when, with the assistance of his brothers Pantagnôtus and Sylosôn, he obtained possession of the island. The three brothers at first ruled conjointly, but after a short time, P. put Pantagnôtus to death, banished Sylosôn, and made himself sole despot. His energetic, unscrupulous, and ambitious character now showed itself more conspicuously than ever. He conquered several islands of the Archipelago, and even some towns on the Asiatic mainland, waged war successfully against the inhabitants of Miletus, and defeated their allies, the Lesbians, in a great sea-fight. His fleet amounted to 100 ships, and was probably at that time the most powerful in all Greece. P. seems to have aspired to the sovereignty of the Ægean, if not also of the cities of Ionia. His intimate alliance with Amasis, king of Egypt, proves the importance in which this daring island-prince was held even by great monarchs. According to Herodotus, Amasis drew off from his alliance through alarm at the uninterrupted good fortune of Polycratés. He dreaded, we are told, the misfortunes that the envious gods must be preparing for so lucky a mortal, and to which his friends would also be exposed. The particular incident that is said to have finally ruptured the alliance is doubtless mythical, but is so well known that we cannot afford to overlook it.

Amasis is reported to have written a letter to P., earnestly advising him to throw away the possession that he deemed most valuable, and thereby avert the stroke of the spiteful gods. P., in compliance with this friendly advice, cast a signet-ring of marvelously beautiful workmanship into the sea, but next day a fisherman presented the 'tyrant' with an unusually big fish that he had caught, and in its belly was found the identical ring. It was quite clear to Amasis now that P. was a doomed man, and he immediately broke off the alliance. So, at least, Herodotus tells the story, but Grote (*History of Greece*, vol. iv. p. 323) suggests—and the suggestion is far more probable—that P., with characteristic perfidy, abandoned the Egyptian for a Persian alliance, when he found the latter likely to be of more value to him in his ambitious designs. When Cambyses invaded Egypt (525 B.C.), P. sent him a contingent of forty ships, in which he placed all the Samians disaffected towards his 'tyranny,' and told the Persian king privately not to let them come back! However, they escaped in some way or other the fate which P. had designed for them, returned to Samos, and made war against the 'tyrant,' but without success. Hereupon, they went to Sparta, and succeeded in enlisting the sympathies of, or, at any rate, in securing the help of both the Spartans and Corinthians. A triple force of Samians, Spartans, and Corinthians embarked for Samos, and attacked the city. After vainly besieging it for forty days, they sailed away, and P. now became more powerful than ever; but Nemesis had her victim after all.

A certain Orotes, the Persian satrap of Sardis, had, for unknown reasons, conceived a deadly hatred against P., and having enticed the latter to visit him, by appealing to his cupidity, he seized and crucified him. Thus perished ignominiously, in the midst of his power and splendor, one of the most famous *thalassocrats*, or sea-kings, of Greek antiquity. He was a patron of literature and the fine arts, and had many poets and artists about his court. His intimacy with Anacreon, in particular, is quite a celebrated thing, and in his praise that joyous bard wrote many songs. To P. also, in all probability, belongs the construction, or at least the enlargement, of those great buildings which Herodotus saw at Samos.

POLYDIPSIA (Gr. *great thirst*) is the term now commonly applied to the disease formerly known as *Diabetes insipidus*. It is characterized, as its name implies, by extreme thirst, and by an enormous discharge of pale watery urine. The affection is one of rare occurrence, and the persons most liable to it are dyspeptics who have passed the period of middle life, and whose bodily powers are failing, although (as the case we shall immediately notice, and one recorded by Dr. Watson, show) it may begin in childhood. The two prominent features of this disease usually lead to the suspicion that true diabetes is present; but the low specific gravity of the urine, and the absence of sugar in it in Polydipsia, and the reverse condition in diabetes, seem to make the distinction easy. Dr. Willis, in his work *On Urinary Diseases*, records the case of a man, aged forty-five, who was admitted for an accident into the Hôtel-Dieu at Paris, and who passed, daily, on an average, thirty-four pounds of urine, and drank thirty-three pounds of water, the normal daily excretion of urine being a little less than two pounds. This person reported that he had been affected in a similar manner ever since his fifth year, and that from the age of sixteen upwards, he had daily consumed not less than two bucketfuls of water, and discharged a commensurate quantity of urine.

Little good can be effected by treatment, further than stimulating the action of the skin by the use of Dover's powder, Turkish baths, &c., and by inducing the patient to take as little drink as may be at all consistent with his comfort.

POLYGALÆÆ, or **POLYGALACEÆ**, a natural order of exogenous plants, herbaceous or shrubby, sometimes twining; the leaves without stipules, and generally simple; the flowers resembling papilionaceous flowers, but the odd petal inferior, and the odd sepal superior; the flower-stalks with three bracts; the calyx of five very irregular sepals; of which the two interior are usually petal-like; the corolla of three, or sometimes five petals, the anterior petal the largest, and often crested; stamens eight, monadelphous or diadelphous, or four and distinct; the ovary superior, generally 2-celled, one ovule in each cell; style and stigma simple; fruit generally a capsule opening by valves, sometimes a drupe. There are about 500 species, diffused throughout all parts of the world.—The genus *Polygala* has a persistent calyx, eight stamens, the lateral sepals large and petal-like, and hairy or wrinkled seeds. The species are very numerous, annual and perenni-

Common Milkwort (*Polygala vulgaris*).

al herbaceous plants, and small shrubs, natives chiefly of warm and temperate climates. One is found plentifully in Britain; the **COMMON MILKWORT** (*P. vulgaris*), a small perennial plant, growing in dry hilly pastures; with an ascending stem, linear-lanceolate leaves, and a terminal raceme of small but very beautiful

flowers, having a finely crested keel. It varies considerably in size, in the size and even shape of the leaves, and in the size and color of the flowers, which are sometimes of a most brilliant blue, sometimes purple, pink, or white.—Several species are natives of the south of Europe.—North America produces a greater number.

The Cape of Good Hope and other subtropical countries produce many beautiful species, some of which have become common ornaments of greenhouses.—*P. Senega* is a North American species, with erect simple tufted stems, about one foot high, and terminal racemes of small white flowers. The root, which is woody, branched, contorted, and about half an inch in diameter, is the **SENEGA ROOT**, **SENEKA ROOT**, or **SNAKE ROOT** of the United States, famous as an imaginary cure for snake-bites, but really possessing important medicinal virtues—stimulating, diuretic, diaphoretic, emmenagogue, and in large doses emetic and purgative—employed in catarrhs, pulmonary affections, rheumatism, low fevers, &c. Its chief active principle is *Polygalic Acid*, $C_{22}H_{18}O_{11}$. The root of *P. Senega* has been employed as a cure for snake-bites by the American Indians from time immemorial, and it is a curious fact, that *P. crotalarisoides* is employed in the same way in the Himalaya. *P. vulgaris* is tonic, stimulant, and diaphoretic; and *P. amara*, a very similar European species, possesses the same properties in a higher degree, as does *P. rubella*, a small North American species. The root of *P. poeyi*, a Brazilian species, with leathery leaves, is an active emetic, and in a fresh state is employed in bilious fevers. Similar properties seem to pervade the whole genus. Another medicinal plant of the order is *Rattany* (q. v.) root. Species of several genera are used as tonics. The bark of the roots of *Morinda polytachia* and *M. salicifolia* is used in Peru as a substitute for soap. *Mundia spinosa*, a South African shrub, produces an eatable fruit.

POLYGAMOUS (Gr. *polys*, many, *gamé*, marriage), in Botany, a term employed to designate those plants which produce both unisexual and hermaphrodite flowers either on the same or different plants. In the Linnean sexual system, these plants formed a class, **POLYGAMIA**, the genera included in which were perhaps more completely disjoined from their natural allies than those of any other class of that system, forming by themselves a very heterogeneous assemblage.

POLYGAMY. See **MARRIAGE**.

POLYGASTRICA. See **INFUSORIA**.

POLYGLOT (Gr. *polys*, many; and *glotta*, tongue) means, in general, an assemblage of versions in different languages of the same work, but is almost exclusively applied to manifold versions of the Bible. The Hexapla (q. v.) of Origen contained besides the Hebrew text, several other versions. All these, however, were in the Greek language; and the Hexapla is not commonly reckoned among the polyglots. They are divided into two classes, the greater and the lesser polyglots. To the former belong four works, known as the Complutensian Polyglot; the Antwerp or king of Spain's Polyglot; the Parisian Polyglot; and the London or Walton's Polyglot.—The Complutensian Polyglot derives its title from Complutum, the Latin name of Alcalá de Henares, where it was printed in 6 vols., folio 1502—1517. It was published at the cost, and under the direction of the celebrated Cardinal Ximenes, who spared no expense, whether in collecting the most ancient and authentic MSS., or in bringing together the most distinguished scholars of all countries for the carrying out of his design. The Complutensian Polyglot contains, besides the Hebrew text, the Septuagint Greek and the Chaldee (each with a literal Latin version), and the Latin Vulgate—the Antwerp Polyglot, so called from its being there printed (1569—1572), at the celebrated press of Plantin, was published at the cost of Philip II. of Spain, under the direction of the distinguished scholar, Benedict Arias Montanus. It is in eight vols. folio, and contains, in the Old Testament, the Hebrew, the Greek, the Targum of Onkelos, and the other Chaldee paraphrases, and the Latin Vulgate. In the New Testament, besides the Greek and Latin, it contains a Syriac version, printed both in Syriac and in Hebrew characters. Arias Montanus was assisted by many scholars of eminence, chiefly of Spain and the Low Countries.—The Parisian Polyglot was printed at Paris in 1645, at the cost and under the editorship of Guy Michel le Jay. It is in ten splendid volumes, and contains, in addition to the contents of the Antwerp Polyglot, another Syriac version, and an Arabic version, together with the Samaritan version and the Samaritan text of the Pentateuch, each of these being accompanied by a literal Latin translation.

The London Polyglot was edited by Brian Walton, afterwards Bishop of Chester, and it engaged for many years a number of the most eminent linguists of the period. The number of its languages is not the same in all parts of the Bible; but it may be said to contain the Bible, or portions of it, in nine languages—Hebrew, Samaritan, Chaldee, Syriac, Arabic, Ethiopic, Persic, Greek (each of these accompanied by literal Latin version), and Latin. It is in six vols. folio, and was published in 1654—1657;

and was followed, in 1669, by the *Lexicon Heptaglotton* of Edmund Castell, two vols. folio, containing dictionaries of all the languages of the polyglot, except the Greek and Latin. Of the minor polyglots, the chief are (1) the Heidelberg Polyglot (1586), Hebrew, Greek, and Latin; (2) Wolder's Polyglot (Hamburg, 1596), Hebrew, Greek, Latin, and German; (3) Hutter's Polyglot (Nürnberg, 1599), Hebrew, Chaldee, Greek, Latin, German, and French; (4) Reineccius's Polyglot, in Syriac, Greek, Latin, and German (Leipzig, New Testament, 1712; Old Testament, 1750, 1751); (5) Bagster's Polyglot, a very valuable collection of modern versions, folio (London, 1831). It contains eight versions in the Old Testament, viz., Hebrew, Greek, English, Latin, French, Italian, Spanish, and German; and nine in the new, Syriac being added to those already named. (6) A useful 'Hand Polyglot,' containing in the Old Testament, Hebrew, Greek, Latin, Vulgate, and Luther's German version; and in the New, Greek, Latin, Luther's German, and in the fourth column, in which are presented the chief differences between this and other German versions.

Besides the Bible, many other works, or small pieces, have been published in polyglot. Of smaller pieces, the Lord's Prayer has been the favorite, of which many collections, containing a greater or less number of languages, have been published from the 16th c. downwards. Of these, the most comprehensive, and, for philological purposes, by far the most valuable, is the well-known *Mithridates* of Adelung, which contains the Lord's Prayer in nearly 500 languages, with vocabularies and grammatical explanations of most of the specimens.

POLYGNOTUS, a distinguished Greek painter of antiquity, was born towards the beginning of the 5th c. B.C. He was a native of the isle of Thasos, and belonged to a family of painters, who came to Athens to practice their profession probably after the subjugation of Thasos by Cimon. P. and his brother, Aristophon, were instructed in the principles of art by their father, Aglaophon. We know almost nothing of their lives, except that P. was a friend of the Athenian general above mentioned, and is said to have been attached to his sister, Elpinice. He died about 436 B.C. P. was a contemporary of the great sculptor, Pheidias (q. v.) and flourished during the supremacy both of Cimon and Pericles; but we hear little or nothing of him under the latter ruler; and although the first painter of his day, it does not appear that he was engaged in the decoration of any of those splendid buildings with which that statesman adorned Athens. It is not at all unlikely that Pericles was averse to patronizing a friend of Cimon, and, at all events, P. was absent from Athens for 14 years (449–435 B.C.) of Pericles's rule, painting at Delphi and elsewhere. His principal works (following a chronological arrangement as far as it can be ascertained) were: 1. Paintings in the Temple of Theseus at Athens. 2. In the Stoa Poecile (or Painted Portico) at Athens, representing the Greek princes after the taking of Troy, assembled to judge of the violation of Cassandra by Ajax. 3. In the Anakeion, or Temple of the Dioscuri, a painting of the marriage of the daughters of Leukippos. 4. In the Temple of Athena Areia at Platea, a picture of Ulysses after having slain the suitors of Penelope. 5. In the Lesché (or 'Conversazione Saloon'), a famous quadrangular court, or peristyle, surrounded by colonnades, built at Delphi by the Cnidians. The walls of this edifice were covered by P. with a series of paintings representing the wars of Troy, and the return of the Greek chiefs, and considered P.'s masterpiece. 6. In the chamber adjoining the Propylæa of the Acropolis. From the criticism of the ancients, it seems quite clear that P. was a great advance on any of his predecessors. He was the first who gave life, character, expression to painting. According to Pliny, he opened the mouth and showed the teeth of his figures; he was the first to paint women with transparent drapery, and with rich head-dresses. Lucian also speaks of his exquisite skill in painting eyebrows and the blush on the cheek; while Aristotle extols the ethical or ideal beauty of his conceptions, saying that P. 'represented men as better than they were,' and finding a parallel for his style in the epic poetry of Homer.

POLYGON (Gr. *polys*, many; *gonia*, a corner), a plane figure, bounded by a number of straight lines; the name is conventionally limited to those plane figures whose bounding straight lines are more than four in number. Polygons of 5, 6, 7, 8, &c. sides are denominated pentagons, hexagons, heptagons, octagons, &c.; and when the number of sides exceeds twelve, the figure is merely mentioned as a polygon of so many sides. The quindecagon, or figure of 15 sides, is the only common exception to this rule. Polygons have many general properties; such as, that the sum of the angles of a polygon, when increased by four right angles, or 360°, is equal to twice as many right angles as there are sides in the polygon, and that (supposing the number of sides of the polygon to be expressed by n) the number of its diagonals is $\frac{n(n-3)}{2}$; also if a polygon of an even number of sides be circumscribed about a circle, the sums of its even and odd sides are

equal; and if a polygon of an even number of sides be inscribed in a circle, the sums of its even and odd angles are equal. A polygon which has all its sides and angles equal is called a *regular* polygon. All polygons of this class are capable of being inscribed in, or circumscribed about, a circle; but though the problem is merely to divide the circumference of a circle into a number of equal parts corresponding to the number of sides in the polygon, geometry was till lately only able to perform it in those cases where the number of sides of the polygon belongs to one or other of the series 2, 4, 8, 16, &c.; 3, 6, 12, 24, &c.; or 5, 10, 20, 40, &c. Gauss (q. v.), however, in the beginning of the present century, showed how it could be done in the case of all polygons the number of whose sides was of the form $2^n + 1$ (provided it be a prime number), or a multiple of this prime number by any power of 2. This discovery supplies us with innumerable series representative of the numbers of the sides of polygons which can be described around or inscribed in a circle, such as 17, 34, 68, &c.; 257, 514, 1028, &c.

POLYGO'NEÆ, or POLYGONA'CEÆ, a natural order of exogenous plants, mostly herbaceous plants, but including a few shrubs, and even trees. The leaves are alternate, sometimes without stipules, but more generally with stipules cohering around the stem. The flowers are not unfrequently unisexual. They have an inferior, often colored perianth, generally in four, five, or six segments; three to nine stamens, inserted into the bottom of the perianth; a one-celled ovary, usually formed of three carpels, but containing only one ovule; styles and stigmas as many as the carpels of the ovary; the fruit generally a nut, often triangular, the seed with farinaceous albumen, which has an economic importance in buckwheat. A few species produce a succulent edible fruit. The order contains nearly 500 known species, natives of almost all parts of the world, but particularly abundant in the temperate regions of the northern hemisphere. Many of the species are common weeds in Britain, as different species of Dock (q. v.) and *Polygonum*. Bistort (q. v.), Buckwheat (q. v.), and Sorrel (q. v.) belong to this order.—The genus *Polygonum* has a colored perianth of five segments, stamens in two rows, styles more or less united at the base, and two or more in number; the fruit invested by the persistent perianth. The species are very numerous. A number are natives of Britain.—KNOT-GRASS (*P. aviculare*), a very common British weed, is one of the plants remarkable for most extensive distribution over the world. It is an annual of very humble growth, but very variable, with much branched trailing stems, small lanceolate leaves, and very small flowers, two or three together, in the axils of the leaves. Thunberg says that in Japan a blue dye is prepared from this plant.

P. amphibium, one of the species often called *Persicaria*, is abundant about margins of ponds and ditches in Britain and throughout Europe, and is remarkable for the difference between the leaves which float on the water, as is often the case, and those on stems growing erect, those of the former being broad and smooth, those of the latter narrow and rough; the spikes of flowers being also of somewhat different form, and the stamens in the flowers of the floating stems shorter than the perianth, in the upright stems about as long as the perianth; differences which might be held to indicate different species, yet both may be found growing from one root. The stems have been used on the continent of Europe as a substitute for sarsaparilla. Some other species are occasionally used for medicinal purposes. *P. hydropiper*, often called WATER PEPPER, a plant common by sides of lakes and ditches in Britain, is acrid enough to be used as a vesicant. Several species are occasionally used for dyeing, as the SPOTTED PERSICARIA (*P. persicaria*), a very common weed on dunghills and in waste places in Britain; but the only species really important on this account is that called DYERS' BUCKWHEAT (*P. tinctorium*), a native of China, biennial, with ovate leaves and slender spikes of reddish flowers, the cultivation of which has been successfully introduced in France and Flanders. It yields a blue dye scarcely inferior to indigo.—*P. orientale* has long been occasionally cultivated in flower-gardens in Britain, and is quite hardy, although a native of the West Indies.—*Fagopyrum cymosum*, a species of buckwheat abundant on the mountains of the north of India, affords an excellent substitute for spinach.—*Muhlenbeckia adpressa* is the Macquarrie Harbor Vine of Tasmania, an evergreen climbing or trailing shrub of most rapid growth, sometimes 60 feet in length. It produces racemes of fruit somewhat resembling grapes or currants, the nut being invested with the large and fleshy segments of the calyx. The fruit is sweetish and subacid, and is used for tarts. *Coccoloba uvifera* is the SEASIDE GRAPE (q. v.) of the West Indies. See also CALLIGONUM.

POLYHY'MNIA, or POLYMNIA ('the Many-hymned One'), one of the nine Muses (q. v.). She was reputed by the ancients to be the inventress of the lyre, and to preside over lyric poetry and eloquence. In works of art, she is usually represented in a

pensive attitude, with the forefinger of the right hand upon the mouth.

POLYMERISM, a form of ISOMERISM (q. v.).

POLYNE'MUS and POLYNEMIDÆ. See MANGO FISH.

POLYNE'SIA, or the region of many islands (*Gr. poly*, much or many, and *nesos*, an island), is the name usually given, with more or less of limitation, to the numerous groups of islands, and some few single islands, scattered throughout the great Pacific Ocean, between the eastern shores of Asia and the western shores of America. In its widest signification, the term P. might be understood as embracing, besides the groups hereafter to be mentioned, the various islands, large and small, of the Indian Archipelago, in one direction; and the vast island of New Holland or Australia, with its dependency of Van Diemen's Land, in another. Including these, the whole region has sometimes been called Oceania, and sometimes Australasia—generally, however, in modern times, to the exclusion of the islands in the Indian Archipelago, to which certain writers have given the name of Malaysia. In proportion, also, as the area of maritime discovery has become enlarged, it has been thought convenient by some geographers to narrow still further the limits of P., to the exclusion of Australia and Van Diemen's Land; while others, again, exclude Papua or New Guinea, New Ireland, Solomon's Isles, the Louisiade group, the New Hebrides, New Caledonia, and certain other groups and single islands, together with New Zealand, from the area of P., and give to these, in union with Australia, the collective designation of Australasia. To all these, with the exception of New Zealand, French writers have given the name of *Melanesia* or the *Black Islands*; while a similar name, *Kelenonesia*, has been given to them by Prichard and Latham—purely, however, on ethnological grounds, as we shall presently notice.

Thus, we have the three geographical divisions of Malaysia, Australasia, and P., the last mentioned of which embraces all the groups and single islands not included under the other two. Accepting this arrangement, still the limits between Australasia and P. have not been very accurately defined; indeed, scarcely any two geographers appear to be quite agreed upon the subject; neither shall we pretend to decide in the matter. The following list, however, comprises all the principal groups and single islands not previously named as coming under the division of Australasia: viz., 1. North of the equator—The Ladrone or Marian Islands, the Pelew Islands, the Caroline Islands, the Radack and Ralik chains, the Sandwich Islands, Gilbert's or Kingsmill's Archipelago, and the Galapagos. 2. South of the equator—The Ellice group, the Phoenix and Union groups, the Fiji Islands, the Friendly Islands, the Navigator's Islands, Cook's or Harvey Islands, the Society Islands, the Dangerous Archipelago, the Marquesas Islands, Pitcairn Island, and Easter Island.

These islands, which extend from about 20° north of the equator to about 80° south of it, are some of them volcanic in their origin, and some of them coralline. The volcanic islands generally rise to a considerable height above the level of the ocean, and are therefore called the high islands, in contradistinction to the coralline or low islands. They consist of basalt and other igneous formations. Of these, the principal are the Friendly Islands, one of which, Otaheite or Tahiti, has a mountain rising to the height of 10,000 feet; the Marquesas Islands, also very high; the Samoan or Navigator's Islands; and the Sandwich Islands, of which Owyhee or Hawaii possesses several both active and extinct craters, 13,000, 14,000, and even 16,000 feet high. The Galapagos group, nearest of all to South America, are likewise of igneous origin, and have several still active craters. The remaining islands are for the most part of coralline formation.

The coral islands (q. v.) may be distinguished into three classes—namely, atolls or lagoon islands, barrier reefs, and fringing reefs. The atolls are rings of coral reefs, surrounding a basin of sea-water of considerable depth, which is enclosed within this area. Examples of these are found in the Caroline Islands, the Dangerous Archipelago, and several other groups. Barrier reefs differ from the atolls chiefly in the fact of their containing an island in their center, the island being separated from the reef by a body of deep water; while the reef is in some instances entirely converted into land, and in others the sea washes over it, except in certain portions, which project above the level of the ocean. Barrier reefs occur among the Society Islands, the Gambier Islands, and many other groups. Fringing reefs are collections of coralline formation, which are found skirting the coasts of an island in the same manner as the barrier reefs, but without any interior deep water channel. They are found in almost all the groups. From the fact of some of these islands being undoubtedly volcanic, it has been argued that all were originally of the same character; those of coralline formation being based upon the crests of submarine volcanoes, over which the coral insects have for an indefinite series of years been engaged in rearing their limestone structures. In opposition to the volcanic theory, Dr. Darwin has propounded one of his own—namely, the theory

of subsidence, which, after mature consideration, he believes to be the only one capable of explaining the various phenomena observable in the coral atolls, barrier reefs, and fringing reefs of the Pacific. All these he considers as being the production of saxigenous insects, working upwards from the foundations of what were originally so many islands, erect above the surface of the ocean, but which during long ages have been in a state of gradual subsidence. With respect to the atolls, he states it as his belief, that the lagoon is precisely in the place which the top of a shoal, and, in other cases, the highest part of an island, once occupied.

So soon as these have sunk to a depth of from 120 to 180 feet below the surface, the coral insects (which it is agreed are never found at a lower depth) commence their operations, and these working on in countless myriads, the sunken island, or a portion of it, is in process of time again reared to the level of the surrounding sea. It would take too long to specify all the phenomena upon which Dr. Darwin has based his ingenious theory, especially those connected with what are called the fringing reefs. It must be mentioned, however, that paradoxical as such a theory may seem, it has received the hearty support of no less distinguished a geologist than Sir Charles Lyell, who, in the early editions of his *Principles of Geology*, having held to the volcanic theory, has since abandoned it for that propounded by Dr. Darwin. Nor is this all; for, in the last edition of Sir C. Lyell's work, we find him mentioning with approval Dr. Darwin's 'important generalization that the Pacific and Indian Seas, and some of the lands which border them, might be divided into areas of elevation and areas of subsidence, which occur alternately.'

Of the islands generally, we need only further observe that, although situated within the tropics, the heat of the atmosphere is delightfully tempered by a succession of land and sea breezes. The soil is exceedingly fertile, and besides the vegetable productions found growing when the islands were first discovered by Europeans, it has given a welcome home to the orange, lemon, sugar-cane, guava, cotton, potato, melon, and other fruits and plants introduced by foreign visitants. The only native quadrupeds on any of the islands when first visited were pigs, dogs, and rats; but the ox, the sheep, the goat, and even the horse, have since been successfully introduced into many of the groups. The feathered tribes are numerous, likewise the insects, and the coasts everywhere abound with a vast variety of fish and crustacean, highly important as a matter of food to the inhabitants of those islands in which quadrupeds, whether native or introduced, are found in only a small number.

For a more particular description of the several groups, we refer to the distinct articles of FIJIS, FRIENDLY ISLANDS, SANDWICH ISLANDS, &c.; and shall now proceed to speak of the inhabitants generally under the head

POLYNESIANS.—This race of people, supposed at one time by certain writers to be of American origin, is now almost universally admitted to have a close affinity with the Malays of the peninsular and Indian Archipelago, and hence is classified with them by Dr. Latham under his subdivision of *Oceanic Mongolids*. In physical structure and appearance, the Polynesiens in general more nearly resemble the Malays than they do any other race, although differing from them in some respects, as, indeed, the natives of several of the groups also do from each other. In stature, they are generally taller than the Malays, and have a greater tendency to corpulence. In color, also, they more nearly approach that of the Europeans. The hair is often waved or curling, instead of long and straight, and the nose is frequently aquiline. These differences, however, which may all have been produced by lapse of time and different conditions of existence, offer no barrier to the strong presumption, that at some long antecedent period these islands were colonized by Malay adventurers. The Malays are known at the present time to be expert and daring sailors, and in the 16th c. were so powerful at sea, that they had frequent naval combats with European fleets in the Indian Archipelago. In 1573, the king of Acheen, with a powerful armament, attacked and destroyed three Portuguese frigates; and in 1582, the same king attacked Malacca with a fleet of 150 sail. At a later period—namely, in 1615, one of his successors attacked the same settlement with a fleet of 500 vessels of various sizes and 60,000 men. If this was their strength and enterprise at a comparatively modern period, may they not have been as enterprising, if not quite so powerful, in far more remote times?

The distance between the more western groups of P. and the eastern islands of the Indian Archipelago is not so great but that it could have been easily overcome by a hardy race of sailors, even although their vessels may have not been so well constructed as in modern times; and the same reasoning holds good with respect to the other groups extending still further east, or still more to the north or south. Each island or group, as it was attained, would only form a convenient point of departure in process of time for some other island or group more remotely situated. It is true that the affinities of language are not great be-

tween the Malays and the Polynesians; still, some affinity has been recognized by philologists; while in their manners and customs a strong resemblance has been shown to exist, as in the institution of caste, the practice of circumcision, the chewing of the betel-nut, and other things. Many other facts might be mentioned in favor of the theory of a Malay settlement, not only of P., but of the islands called Melanesia or Kelenonesia as well; the last mentioned being inhabited by a race almost identical with the Negritos or Pelagian Negroes of the Eastern Archipelago. Dr. Latham, in treating of the Polynesians, divides them into two branches—viz., 1. The Micronesian branch, and 2. The Proper Polynesian branch. His theory as to the probable line of migration is as follows: 'The reason for taking the Micronesian branch before the Proper Polynesian, involves the following question: What was the line of population by which the innumerable islands of the Pacific, from the Pelews to Easter Island, and from the Sandwich Islands to New Zealand, became inhabited by tribes different from, but still allied to, the Protoneesian Malays? That line, whichever it be, where the continuity of successive islands is the greatest, and whereon the fewest considerable interspaces of ocean are to be found. This is the general answer *à priori*, subject to modifications from the counterbalancing phenomena of winds or currents unfavorable to the supposed migration. Now, this answer, when applied to the geographical details regarding the distribution of land and sea in the great oceanic area, indicates the following line: New Guinea, New Ireland, the New Hebrides, the Fijis, and the Tonga group, &c.

From hence, the Navigator's Islands, the isles of the Dangerous Archipelago, the Kingsmill and other groups, carry the frequently diverging streams of population over the Caroline Islands, the Ladrões, the Pelews, Easter Island, &c. This view, however, so natural an inference from a mere land and sea survey, is complicated by the ethnological position of the New Guinea, New Ireland, and New Hebrides population. These are *not* Protoneesian, and they are *not* Polynesian. Lastly, they are not intermediate to the two. They *break*, rather than propagate the continuity of the human stream—a continuity which exists geographically but fails ethnographically. The recognition of this conflict between the two probabilities has determined me to consider the Micronesian Archipelago as that part of Polynesia which is most likely to have been first peopled, and hence a reason for taking it first in order.' The islands comprised in the Micronesian branch are the Pelew Islands, the Caroline Islands, the Marian Islands, and the Tarawan or Kingsmill group. In physical appearance, the inhabitants of these groups more nearly resemble the Malays than is the case with the Polynesians Proper. In person, they are not so tall as the latter. Their language has numerous dialects, most of which would perhaps be unintelligible to the groups further south and east. In religion, they are pagans; but their mythology and traditions differ from those of the Polynesians Proper. Neither is the custom of the taboo and the use of kava so prevalent as they are found to be among the latter. The Proper Polynesians, so called, are found in the Fiji Islands, but not to the same extent as in the following—viz., the Navigator's or Samoan Islands, the Society Islands, and Friendly Islands; also in the Sandwich Islands, the Marquesas, the Dangerous Archipelago, &c. In physical appearance, they are the handsomest and tallest of all the natives of the Pacific Islands, with the exception, perhaps, of the New Zealanders or Maoris.

The aquiline nose is commonly seen among them, and there are many varieties both of hair and complexion. Their face is generally oval, with largish ears and wide nostrils. In the islands nearest to the equator, the skin is said to be the fairest, and it is darker in the coral islands than in the volcanic. Their language is said to bear some affinity to the Tagala, and is split up into numerous dialects, all, however, to a great extent mutually intelligible among the several groups. Paganism, originally prevalent among all the groups, is becoming gradually extirpated through the efforts of the missionaries, principally English and American, as in the Samoan, Sandwich, and Society groups, where but few absolute pagans now remain. The superstition of the taboo, the use of kava as an intoxicating drink, cannibalism, infanticide, tattooing, and circumcision, which were also formerly prevalent in all the groups, are now fast disappearing, under the influence of Christianity. Unfortunately, however, the contact of these islanders with civilization has not been always productive of unmixed good; the introduction among them of the use of ardent spirits, and of the vices and diseases of Europeans, having thinned the population to a lamentable extent. Further particulars with respect to the natives of P. will be found in some of our articles on the groups regarded as being the most important.

POLYPHEMUS, in the Homeric mythology, the son of Poseidon and the nymph Thoosa, the most celebrated of the fab-

ulous Cyclops (q. v.), who inhabited the island of Sicily. He was of immense size and had only one eye. When Ulysses landed on that island, he entered the cave of P. with twelve companions, of which number this tremendous cannibal ate six. The others stood expecting the same fate, but their cunning leader made P. drunk, then burned out his single eye with a blazing torch, and so escaped, leaving the blinded monster to grope about in the darkness.

POLYPHEMUS, a genus of *Branchiopoda* (q. v.), of the order *Cladocera*, remarkable for the extraordinary size of the solitary eye, which occupies almost the whole head. One species, *P. stagnorum*, is common in stagnant pools and ditches in some parts of Britain and of the continent of Europe. It is about the size of a flea, and moves rapidly in the water, executing all kinds of evolutions, employing both its legs and antennæ as organs of swimming. The shell, consisting of two pieces, is so transparent that all the viscera may be seen through it. The abdomen is terminated by a long tail suddenly folded back.

POLYPHONIC (Gr. *polys*, many, and *phoné*, voice). When a musical composition consists of two or more parts, each of which has an independent melody of its own, it is said to be polyphonic, in opposition to a homophonic composition, consisting of a principal part with a leading idea, and accessory parts employed to strengthen it. Each part of a polyphonic composition aims at melodic perfection, and while supporting the other, has an equal share in the entire effect, as in the following example:

A fugue (q. v.) is the most perfect example of polyphonic composition. The difference between homophonic and polyphonic compositions is not always so marked as to leave it free of doubt whether a part is subordinate or independent; and many compositions consist of an alternation of homophonic and polyphonic passages. The construction of polyphonic phrases is called Counterpoint.

POLYPI, or POLYPES, a class of animals which were, till the last few years, included in the *RADIATA* of Cuvier, but which, since the *Radiata* have ceased to be regarded as a sub-kingdom, have found a place in the sub-kingdom *CELENERATA*. See *SUB-KINGDOMS, ANIMAL*. The name *Polypi*, or *Polypes*, was given by Reaumur about the middle of the last century to these animals, on account of their external resemblance to the many-armed cuttle-fishes, which were so denominated by Aristotle; and our knowledge of these organisms, as members of the animal kingdom, hardly dates back much more than a century. All polypes are aquatic in their mode of life, and almost all of them are inhabitants of the sea, two genera only (*Hydra* and *Cordylophora*) of fresh-water polypes being as yet known. Most of them live in societies of considerable extent, supported on a common stock, to which the term *polypidom* (polyp-home) is usually given, and which is sometimes horny and sometimes calcareous. The polypes are either embedded in cavities in the substance of the calcareous polypidom, or enclosed in minute cups or tubes, from which the body can be protruded, and into which it can be retracted at pleasure, in the horny polypidoms. The solitary species often attain a considerable size (as, for instance, many of the *Actinias*); but the social polypes are always minute, although the combined power of some of the species in modifying the earth's crust is neither slight nor limited in extent. 'They have built up a barrier reef along the shores of New Caledonia for a length of 400 miles; and another, which runs along the north-east coast of Australia, 1000 miles in extent. To take a small example: a single atoll (or coral island) may be 50 miles in length by 20 in breadth; so that if the ledge of coral rock forming the ring were extended in one line, it would be 120 miles in length. Assuming it to be a quarter of a mile in breadth, and 150 feet deep, here is a mound, compared with which the walls of Babylon, the great wall of China, and the pyramids of Egypt are but children's toys; and built, too, amidst the waves of the ocean, and in defiance of the storms.'—Owen, *Lectures on the Invertebrate Animals*, 2d edit., p. 143.

The bodies of these animals are generally soft, and cylindrical or oval in shape; and the mouth, which is the only aperture of the digestive canal, and is quite destitute of any masticating apparatus, lies in the center of the anterior or free extremity of the body, and is surrounded by a fringe or circle of tentacles or arms. The skin in the social polypes is exceedingly soft and delicate; but in the solitary species, it is often of a leathery consistence. It almost always contains peculiar urticating organs, or thread-like cells, which may be regarded as one of the distinctive charac-

ters of the Cœlenterata. Various arrangements of the polypes have been proposed, but it is sufficient for all practical purposes if we admit two orders—namely, the *Hydrozoa* and the *Anthozoa* (or *Actinozoa*), which differ essentially in the following points: in the *Hydrozoa*, the wall of the digestive sac is not separated from that of the somatic (or bodily) cavity, and the reproductive organs are external; while in the *Anthozoa*, the wall of the digestive sac is separated from that of the somatic cavity by an intervening space, subdivided into chambers by a series of vertical partitions, on the faces of which the reproductive organs are developed. The *HYDRA* (q. v.), or Fresh-water Polype, is the type of the *Hydrozoa*. A few of these polypes are simple animals, as, for example, *Hydra*, *Corymorpha*, *Vorticella*, and *Myriothela*; but the greater number are compound or composite, exhibiting a numerous colony, connected with one another by a common trunk or *cœnosarc* (from the Gr. *κοινος*, common, and *σαρξ*, flesh), which usually presents an erect tree-like form.

A sufficient idea of the form and structure of the simple polypes of the class will be obtained by a reference to the article *HYDRA*, and by a glance at the accompanying figure of *Corymorpha nutans*, which attains a length of between four and five inches, and was discovered by Forbes and Goodsir when dredging in the north of Scotland. They observe, that when it was placed in a vessel of sea-water, it presented the appearance of a beautiful pink flower, its head gracefully nodding (whence the specific name given to it by Sars, who had previously discovered it on the Norwegian coast), and bending the upper part of the stem; it waved its long white tentacles to and fro at pleasure, but seemed to have no power of contracting them. The compound *Hydrozoa* include, *inter alia*, the orders *Sertulariida* (embracing the various species of *Sertularia*, *Campanularia*, *Laomedea*, &c.) and *Tubulariida* (embracing the various species of *Tubularia*, *Eudendrium*, *Bimeria*, &c.). A good idea of the nature of the compound *Hydrozoa* may be formed from the consideration of the *Campanularia dichotoma*, a common organism on our shores. The compound polype-animal, or association of polypes, resembles a miniature tree. It consists

to the respiratory process. 'At certain points of these ramified polypes,' says Professor Owen, 'which points are constant in and characteristic of each species, there are developed little elegant vase-shaped or pod-shaped sacs, which are called the ovigerous vesicles, or *ovicapsules*. These are sometimes appended to the branches, sometimes to the axillæ, as at *h*, *i*, *k* (in fig. 2). They are at first soft, and have a still softer lining membrane, which is thicker and more condensed at the bottom of the vesicle. It is at this part that the ova or germs are developed, and for some time these are kept in connection with the vital tissue of the polype by a kind of umbilical cord. In all the compound *Hydrozoa*, the *ovicapsules* are deciduous; and having performed their functions in relation to the development of the new progeny, drop off like the seed-capsules of plants.' On other individuals of the same species, sperm-capsules are developed, which, in form, resemble the *ovicapsules*, but in place of ova, contain spermatozoa. The act of fertilization in most cases occurs by diffusion of the spermatozoa in the surrounding water. There is much that still requires elucidation in reference to the various modes of reproduction of this class. Many of the *Hydrozoa* have been shown to be merely larval forms of Medusæ. See GENERATIONS, ALTERATION OF.

The leading anatomical distinction between the *Anthozoa*, or *Actinozoa*, and the *Hydrozoa*, has been already noticed. The common *Actinia* (q. v.) may be regarded as the type of this class, all of which are marine, and principally inhabit the warmer or tropical seas. Many of the larger tropical polypes of this class combine with the structure similar to that of the *Actinia* an internal calcareous axis or skeleton, which, penetrating into the interior of the organism, presents the lamellated and radiated structure recognizable in the *Fungia*, and in the skeletons of *Caryophyllæ*, *Madreporeæ*, &c. Such *Anthozoa* are termed coralligenous; and every hard structure deposited in or by the tissues of this class, and forming a uniform framework, is recognized by zoologists as a coral. Like the members of the preceding class, many of the *Anthozoa* multiply freely by gemmation, complex or compound animals or colonies of animals being formed, in

Fig. 1.—*Corymorpha nutans*.

Fig. 2.—*Campanularia dichotoma*, magnified.

essentially of a ramified tube of irritable matter, *f*, defended by an external flexible, and frequently jointed horny skeleton, *a*; and is fed by the activity of the tentacula, *d*, and by the digestive powers of the alimentary sacs (*g*) of a hundred polypi, the common produce of which circulates through the tubular cavities for the benefit of the whole community. The soft integument of the nutrient polyges (*d*, *e*, *g*) contains the thread-cells, to which alulion has previously been made. These are protruded when the skin is irritated, and give the tentacles the appearance of being beset by minute bristles. The digestive sac of each polype is lined by a ciliated epithelium; but there is a perforation at the base communicating with the central tube, *f*. This outlet admits only of the passage of the fluid contents of the stomach, undigested matters being ejected by the mouth.

There is reason to believe that sea-water enters the branches of the tube *f*, and circulates, by means of the ciliated epithelium, through the compound organism; and by this means contributes

Fig. 3.—Diagram illustrating the Morphology of *Anthozoa*. *a*, polype of *Alcyonium*; *b*, ideal section of the same; 1, 1, 1, &c., the somatic cavity, divided by the mesenteries, 2, 2, 2, &c., into eight chambers; 3, the digestive cavity.

which individual polypes are united by a *cœnosarc* or polypidom. For a description of the mode in which communication takes place between the common body or mass and the individual polypes, we must refer to the article *ALCYONIUM*. Various arrangements of this class have been proposed by zoologists. If we exclude the consideration of fossil genera, we may divide the *Anthozoa* into two orders—the *Alcyonaria* and the *Zoantharia*.

The *Alcyonaria* may be characterized as *Anthozoa* in which each polype is furnished with eight tentacles, not simple, as in *Actinia*, but furnished with pinnate margins, with eight somatic chambers, and eight mesenteries. With the exception of one genus, they are all composite in structure; their polypes being connected with one another by a *cœnosarc*, which is traversed by prolongations of the somatic cavity of each polype, a system of canals being thus formed whose parts freely communicate and are readily distensible. Carus, in the *Handbuch der Zoologie*, 1868, vol. 2 (of which he is joint author with Peters and Gerstaecker), mainly adopting Milne-Edwards's arrangement, divides the *Alcyonaria* into the three following families: 1. *Alcyonidae*; 2. *Gorgonidae*; 3. *Pennatulidae*. In the *Alcyonidae*, he includes the beautiful organ-pipe corals, of which Green and others make a separate family. The polypidom constructed by *Tubipora musica* consists of successive stages of cylindrical tubes of a rich crimson color, united at various heights by means of horizontal connecting

plates. The tubes placed upon the upper stage are alone inhabited by living polypes, of a violet or green color, the occu-

Fig. 4.—*Tubipora musica*.

plants of those below having successively perished as fresh generations appeared above them. As an example of the *Gorgonidae*, we may take *Isis hippuris*, in which the skeleton is made up of alternate joints of calcareous and horny matter, with the view

Fig. 5.—*Isis hippuris*.

of giving the necessary flexibility. In the *Pennatulida*, the polypidom is free, and no polypes are attached to its basal portion. The *Sea-pens* (*Pennatula*) of our own coast afford a good example of this family. See PENNATULA for description and figure.

The *Zoantharia* may be characterized as Anthozoa in which the tentacles are either simple or branched, in general numerous, and together with the mesenteries, disposed in multiples of five or six. They may be arranged in the three following sub-orders—1. *Z. Malacodermata*; 2. *Z. Sclerobasica* or *Antipatharia* (Milne-Edwards); and 3. *Z. Sclerodermata* or *Madrepores*. The first sub-order has been variously subdivided into families and sub-families, which it is unnecessary to notice. It contains all the sea-anemones and animals allied to them, including the genera *Actinia*, *Anthea*, *Corynactis*, *Capnea*, *Adamsia*, *Ilyanthis*, *Sagartia*, *Bunodes*, *Edwardsia*, *Peachia*, &c.; and the *Zoanthida*, which are aggregated polypes arising from a common creeping root-like fleshy band, and of which at least one species, *Zoanthus Couchii*, is an inhabitant of the British seas. All the members of the second sub-order are composite structures. *Antipathes*, the type of the group, presents a stem-like, simple, or branching cenosarc, which in one species tapers to a length of more than nine feet, with a diameter, at the base, not exceeding three-tenths of an inch. The third sub-order (the *Madrepores*) is a very extensive one. It is divided into the *Madrepora aporosa* and *M. perforata*, according as the coral exhibits a solid or a porous structure. *M. aporosa* may be arranged in the following families—1. *Turbinolida* (including the sub-families *Caryophyllina* and *Turbinolina*); 2. *Oculinida*; 3. *Astræida*; 4. *Echinoporina*; 5. *Merulinacea*; 6. *Fungida*; while the *M. perforata* are divided into (1) *Madreporida* and (2) *Poritida*. A few

of the commoner forms of *Madrepora* are delineated in the articles CORAL and MADREPORE. Amongst the most important works on this department of zoology may be mentioned Dana's *Structure and Classification of Zoophytes* (Philadelphia, 1846), and his *Report on Zoophytes*, and *Atlas of Zoophytes* (U. S. exploring Expedition), 1849; Johnston's *British Zoophytes*, in 2 vols., to which we are indebted for many of our illustrations; Milne-Edwards and Haime, *Histoire Naturelle des Coralliaires ou Polypes proprement dits* (3 vols., 1857—1860); and Lacaze-Duthiers, *Histoire Naturelle du Corail, Organization, Reproduction, &c.* (1864).

POLYPO'DIUM, a genus of Ferns, with spore-cases on the back of the frond, distinct, ring-shaped, in roundish *sori*, destitute of *indusium*. Several species, differing very considerably in appearance, are natives of Britain, where no fern is more com-

Polypodium :
1, *P. dryopteris*; 2, *P. vulgare*.

mon than *P. vulgare*. It grows on rocks, trees, dry banks, &c., and has fronds 2—18 inches long, deeply pinnatifid, with large *sori*.—*P. Dryopteris*, with delicate ternate bipinnate fronds, is a fine ornament of many dry stony places in Scotland.—*P. Calaguala*, a native of Peru, is said to possess important medicinal properties—solvent, deobstruent, sudorific, &c.

POLYPO'RUS. See AMADOU and DRY ROT.

POLYPTERUS, a genus of fishes, ranked by Cuvier among malacopterous fishes and in the family *Clupeidae*, notwithstanding very important differences of structure; but now constituted by Müller and others into a family, *Polypteridae*, of the order of Ganoid Fishes. The shape is round and elongated; the head defended by large bony plates, the body covered with large and strong ganoid scales, which are very closely affixed to the skin. These curious fishes, existing remains of a type which was prevalent in former geologic periods, inhabit the rivers of Africa, and lodge in the soft mud. Their flesh is very pleasant. The *P.* of the Nile, called *Bichir* by the Egyptians, is said to be one of the finest fishes of that river. It is about 18 inches long.

PO'LYPUS, in Surgery, is an antiquated term employed to signify any sort of pedunculated tumor attached to a surface to which it was supposed to adhere like a many-footed animal, as its name indicates. The most common seat of polypus is the mucous membrane, especially that of the nostrils and uterus; but these tumors are also found in the rectum, the larynx, and the external auditory passage of the ear. The only satisfactory mode of treatment consists in their removal, which must be effected in various ways, according to their position, as by the forceps, the ecraseur, the ligature, &c.

PO'LYSTYLE, a term applied to a building with a number of columns, but not the strict number of any of the classic arrangements.

POLYTECHNIQUE (*École Polytechnique*), or POLYTECHNIC SCHOOL (Gr. *polys*, many; *techné*, art), was first established in Paris (1794) by the National Convention, under the name of *École des Travaux publics* (School of Public Works). No students were admitted but those who intended to enter the public service; and though the general object of the institution was the supplying of well-educated youths to all branches, it was more particularly devoted to the thorough instruction of recruits for the corps of civil and military engineers. The institution received the name of 'École Polytechnique' in 1795. The pupils were at first 349 in number, and each received, during his stay of two years in the institution, an annual stipend of 1200 francs (£48 nearly); the teachers were in most cases the most eminent savans

of France. In 1799, some modifications were introduced into the working of the school; the number of pupils was at the same time limited to 200, and they were put into uniform. The advantages of an institution of this sort, when ably conducted, soon made themselves evident, and the P., in consequence, rose into high estimation, not only in France, but throughout Europe, so much so, that it became common for foreign nations, when entering into a treaty with France, to stipulate for the admission of a certain number of their subjects into the institution, after passing the prescribed entrance examination. In 1804, the Emperor Napoleon introduced various modifications into its working, and gave it a military organization; it was also removed from the Palais-Bourbon (where it had existed from its first establishment) to the old college of Navarre. The institution became more and more, as the end of the Napoleonic empire drew near, a training-school for young artillerymen and engineers; and such was the enthusiasm of the pupils in the emperor's cause, that, after the disasters of 1814, they demanded to be enrolled *en masse* in the ranks of the French army. However, Napoleon was (to use his own words) not inclined 'to kill the hen for the golden eggs;' but he allowed them to form three out of the twelve companies of which the artillery corps of the national guard was composed. These three companies rendered important service in manning the walls of Paris, and behaved heroically in the battle of March 30, 1814.

After the first Restoration, the P., being considered to be evil-disposed to the government, suffered considerable reductions; but was restored to its former importance for the brief period of the 'Hundred Days.' After the second Restoration (July 1815), the staff of Professors was remodelled; Lacroix and some others were dismissed, and replaced by Poisson, Arago, Cauchy, &c. Notwithstanding these changes, the government still had its doubts as to the loyalty of the establishment, and took advantage of an outbreak, April 3, 1816, to break it up. It was reconstituted in September of the same year, under a revised code of regulations, and in 1822 the old severity of military discipline was restored. During the war of 1870—1871, the government of national defence ordered the pupils to meet at Bordeaux, and classes were opened there under distinguished pupils of the school brought from all parts of France. However, the attempt had to be abandoned and the pupils having sought permission to take part in the war, were divided among the different sections of the army in which their services were highly appreciated. The constitution of the school, which has so frequently suffered change, was in the end of 1873 regulated by *décret* of 30th November 1863, and ministerial rules issued on 5th March 1857. 1. No pupil can be admitted unless he has been successful in the public competitive examination which is held each year. 2. The conditions of admission to the competitive examination are, that the candidate shall be a Frenchman; that he shall be more than 16, and less than 20 years of age, on the 1st of January of that year; and that he shall be either a Bachelor of Letters or a Bachelor of Sciences of the University of France. If he holds both degrees he is allowed 50 marks in the examination for admission. 3. Regular soldiers are admitted up to the age of 25 years, provided they have been on real and effective service for two years. 4. The charge for board is 1000 francs (£40) per annum, and the cost of outfit (to be also paid by the pupil) about 600 francs. 5. The duration of the course of instruction is two years: the pupils, after finishing their course, must pass a final examination; the successful candidates, if found to be physically qualified, are arranged in order of merit, and choose in order what branch of the public service they wish to enter. 6. The branches of the public service which are recruited from the P. are, the corps of land and naval artillery, military and naval engineers, the imperial marine, the corps of hydrographic engineers, that of engineers of roads, bridges, and mines, the corps of staff-officers, the superintendence of telegraphs and gunpowder and tobacco manufactories; and generally every department which, requiring special scientific knowledge, may be added by *décrets* to these.

The following branches of study were embraced in the curriculum in 1873: Mathematics, physics, chemistry and chemical manipulation, history and literature, German, written exercises, drawing, geodesy, mechanics, architecture, art militaire. Lessons in fencing, music, and dancing, are given out as optional, and must be separately paid for. The number of pupils varies with the requirements of the public service. In 1794, there were 396 pupils; in 1820, only 66. During the first empire, the numbers increased from 110 in 1808, to 227 in 1813; under Louis Philippe the average number was 130. During the second empire, it had risen to 140 and 150. After the war with Germany in 1870-71, the number rose to 260. The numerous and admirably equipped technical schools of Germany (see TECHNICAL EDUCATION), often called *Polytechnica*, have received no military restriction, and are available for all interested in the industrial arts; they are in many cases scientific centers comparable to the universities.

POLYTRICHUM (Gr. many-haired), a genus of mosses, having the capsule supported on a stalk (*seta*) which is terminal, and thus appears as an elongation of the stem; the peristome single, of 32 of 64 short equidistant teeth, which are curved inwards, and their summits united by a horizontal membrane closing the mouth of the capsule. A number of species are found in Britain, of which the most abundant is *P. commune*, sometimes called *Hair-moss*, *Golden Maidenhair*, and provincially *Goldilocks*; growing in heaths and woods, particularly where the soil is sandy; the stems not at all branched, or only at the base, several inches long; the narrow slender leaves sometimes nearly half an inch long. This beautiful moss is very common in the most northern parts of Europe and Asia.

POLYZO'A, known as a BRYOZOA (from the Greek *bryon*, moss, and *zoon*, an animal; because many of these organisms in-crust other animals or bodies like moss), and CILIOBRACHIATA (from the circumstance that their tentacles are ciliated), are so called from many individuals being united into a colony or polyzoary. Although Dr. Grant, in his *Observations on the Structure and Nature of Flustra*, in 1827, and Milne-Edwards and Audouin, in their *Résumé des Recherches sur les Animaux sans Vertèbres faites aux Îles Chaussey* in 1828, indubitably showed that these animals more closely resembled, in the details of their organization, the molluscs than the radiate sub-kingdom, with which they were formerly confounded, some of our most esteemed English writers (including Professor Owen) persist in retaining them among the Polypes, instead of placing them in their true position amongst the molluscoid animals.

Most of the P. are microscopic, but as they occur in colonies, they often collectively form sufficiently conspicuous masses, and although there is little diversity in the form or structure of the animals themselves, there is much difference in the form, arrangement, and composition of the cells or chambers in which the individual animals reside. 'In general,' says Mr. Gosse, 'the form of the cell is ovate or oblong; but the general shape is variously modified, being tubular, club-shaped, horn-shaped, cradle-shaped, square, &c.'

The arrangement is often shrub-like, or the cells may be arranged in close series, either adhering in irregular patches, as the *Lepralia*, or rising into broad, flexible leaves, as the *Flustra*, or common sea-mats, or in solid strong walls, or coral-like masses, as the *Escharella*, or calcareous sea-mats. Each animal lives freely

Escharella Cervicornis :

A, portion of its coralline fabric, of the natural size; B, portion of a young branch, enlarged, to show the arrangement of the superficial apertures; C, an individual withdrawn from its cell and highly magnified; a, mouth; b, pharyngeal cavity; c, secreting tubes; d, the digestive stomach; e, the intestinal canal; f, the anus; g, retractor muscles.

in its cell, with whose walls it is connected only by means of muscular bands and threads at certain points, and by the covering of the mouth of the cell. The animal may either expand itself to a considerable extent out of the mouth of the cell, or it may be altogether restricted within the latter; their movements being due partly to pressure upon the outer walls, and partly to the muscular bands, which act chiefly as retractors. On examining one of these organisms in the expanded state, the mouth is seen to be surrounded by a crown of tentacles, which are most commonly ten or twelve in number, and are clothed with vibratile cilia, which lash the water towards the mouth, and thus create numberless little whirlpools, by which nutritious matter is conducted into the oral aperture of the polyzoa. These ciliated tentacles, which are seen in C, a, in the figure, constitute one of the essential points of difference between these animals and the hydriform polypes, with which they were formerly associated. The mouth leads to a funnel-shaped cavity or pharynx b, which is suc-

ceeded by an œsophagus *c*, and a true digestive stomach *d* (between which a muscular gizzard intervenes in certain genera), after which the intestine, *e*, turns back upon itself, and terminates in an anus, *f*, near the mouth. In the separate intestine and anal orifice, we have another characteristic distinguishing these animals from the polypes. At the base of the tentacular circle, just above the anal orifice, is a nervous ganglion, which in all the *P.* lies on the re-entering angle, between the two extremities of the intestinal canal. No heart has as yet been discovered, the matters, which result from digestion, percolating through the intestinal walls, and becoming mixed with the fluid in which the viscera floats. According to Professor Allman, three distinct modes of reproduction occur in the *P.*, viz., by buds or gemmæ, by true ova, and by free locomotive embryos. This subject, however, requires further investigation.

Minute appendages, of a very remarkable character, are fixed to the cells of many of the genera. They are termed *Avicularia*, or 'Birds'-head Processes,' and *Vibracula*, or whip-like spines. The *Avicularia* were described by Ellis, who first noticed them (in his *Essay towards a Natural History of the Corallines*, 1758), as resembling 'a bird's head with a crooked beak, opening very wide;' they consist of a fixed and a movable nipper, like a crab's claw, the latter being worked by special muscles. These moving beaks have been often observed to seize minute animals; but as these organs have no power of passing their prey to the mouth, the *P.* cannot receive nourishment from this source. Mr. Gosse ingeniously suggests that 'the seizure of a passing animal, and the holding of it in the tenacious grasp until it dies, may be a means of attracting the proper prey to the vicinity of the mouth.' The *vibracula* consists of a long, slender movable *seta* or bristle, which, according to Gosse, serves 'to rid the animal of intruding vagrants, and to cleanse away accidental defilement, by sweeping across the orifice of the cell.' Both these kinds of organs are of service in determining genera. Excellent magnified representations of the *Avicularia* and *Vibracula* may be seen on referring to figs. 13 and 11, in Mr. Busk's excellent article, POLYZOA, in *The English Cyclopædia*, to which, as also to that gentleman's *Catalogue of Marine Polyzoa in the British Museum*, and to Professor Allman's 'Report on the Freshwater Polyzoa,' published in the *Reports of the British Association* for 1850, the reader is referred for further information regarding this remarkable class of animals.

POMA'CEÆ, or POME'Æ, according to some botanists, a natural order of plants, but more generally regarded as a suborder of ROSACEÆ (q. v.). The plants of this order are all trees or shrubs, abundant in Europe, and chiefly belong to the temperate and colder regions of the Northern Hemisphere; they are rare in very warm climates, and are not found at all in the southern hemisphere. They have the botanical characters described in the article ROSACEÆ (q. v.), and in addition are distinguished by having the tube of the calyx more or less globose, the ovary fleshy and juicy, lined with a thin disc, its carpels adhering more or less to the sides of the calyx and to each other; the fruit a *Pome* (q. v.), 1—5-celled, in a few instances spuriously 10-celled; the ovules in pairs, collateral. Many of the species are prized for the beauty and fragrance of their flowers, some produce valuable timber; but the order is chiefly remarkable as producing a number of the very finest fruits of temperate climates. See APPLE, PEAR, QUINCE, MEDLAR, LOQUAT, HAWTHORN, CRATÆGUS, AMELANCHIER, ROWAN, SERVICE.—There are about 200 known species.

POMA'DE, or POMATUM, is a preparation used instead of liquid oil for the hair. It consists of a fine inodorous fat, such as lard or suet; but neither of these are quite free from smell, and the most careful perfumers render them so by a peculiar process. They melt them in a steam-bath, and to every $\frac{1}{2}$ of cwt. add 1 oz. of alum and 2 ozs. of salt, continuing the action of the heat till any scum ceases to rise; the scum is carefully removed, and the fat allowed to cool, after which it is levigated with cold water with great care and patience until every particle has been acted upon, and the salt, alum, and albuminous matters are perfectly washed out, after which it is remelted in the steam-bath, and any remaining water falls to the bottom: when cold, it is fit for use. The perfumer then takes portions of this prepared fat, and remelting each separately, adds a little wax or spermaceti to give it consistency, and perfumes it with some essence. The varieties of pomades are as numerous as the perfumed essences. Anciently, they were made by boiling over-ripe apples in fat, by which the peculiar smell of the fruit was communicated, and this originated the name, which is derived from *pomum*, an apple.

POMBAL, DOM SEBASTIAO JOSE DE CARVALHO, MARQUIS OF, the greatest of all Portuguese statesmen, and one of the ablest men of his time, was born 13th May 1699, at the castle of Soura, near Coimbra. His father, Manuel de Carvalho, was a captain of cavalry, and belonged to the second grade of nobility. After studying law at Coimbra, and serving a short time in the

army, P. was banished from Lisbon on account of his youthful turbulence of disposition, and retired to his birthplace, where he devoted himself for a while to study. Subsequently, he married a rich widow, Donna Teresa da Noronha Almada, and repaired to court. In 1739, he was appointed envoy-extraordinary to the court of London through the influence of his uncle, Paulo Carvalho, a position which he held for six years, after which he was sent to Vienna in a similar capacity. Here P. (whose first wife was now dead) espoused, in 1749, Leonora Ernestina, Countess Daun, niece of the famous Austrian marshal of that name. This marriage had a most felicitous influence on his future career. When P. returned to Portugal, the Portuguese queen, who was an Austrian princess, conceived a great attachment to his wife; and when her son, Joseph I., ascended the throne in 1750, she induced him to appoint P. state secretary for foreign affairs. Immediately, his splendid administrative genius burst forth like a sudden blaze of sunshine. He found his country almost without an army, without a fleet, without commerce or agriculture, and all power in the hands of unscrupulous Jesuits and grasping nobles. Among his first acts was to re-attach to the crown a great number of domains that had been unjustly alienated. Then followed the re-organization of the army, the introduction of fresh colonists into the Portuguese settlements, the establishment of an East Indian Company, and another for Brazil, where he introduced the cultivation of coffee, sugar, cotton, rice, indigo, and cocoa.

In virtue of a treaty with Spain, signed in 1753, Paraguay became an appanage of the Portuguese crown, and it was in this remote region that P. first came into collision with the Jesuits—the founders of the Paraguay missions. He got his brother, Francisco-Xavier de Mendonça, appointed captain-general of Paraguay, and is said to have given him secret instructions to ruin the Jesuits in his reports to the king. When the great earthquake happened at Lisbon in 1755, P. displayed an almost superhuman courage and energy, in consequence of which the king raised him to the rank of Count of Eyras, and in the following year appointed him prime minister. He crushed a revolt instigated by the great nobles and the Jesuits, the latter of whom he now removed from the person of the sovereign, deprived of the power of the confessional, and in 1757 confined to their colleges. A conspiracy against the life of the king, which broke out 3d September 1758, but failed, placed his enemies completely in his power. The leaders were punished with appalling severity. The Duke of Aveiro and the Marquis of Tavora were broken alive on the wheel, the sons and the son-in-law of the former were strangled, and the wife of the marquis was beheaded. The Jesuits were suspected of complicity in the plot, and P. accused them to the pope; and when the latter would not allow the minister to proceed against them in the civil courts, he daringly caused some to be executed in prison. Father Malagrida, who had prophesied the death of the king, was delivered over to the Inquisition as a heretic, and condemned to be burned alive; and this *auto da fé* actually took place in 1761! But P. was not satisfied. He had made up his mind that the very presence of the Jesuits in Portugal was incompatible with the security of the government and the welfare of the nation, and by a royal decree of 3d September 1759, they were banished from the kingdom as rebels and enemies to the king. When they refused to leave, P. had them violently removed by soldiers, carried on board ships, and transported to the States of the Church.

The pope, Clement XIII., vehemently protested, whereupon P. caused the papal nuncio to be shown across the frontier. Shortly after, Clement XIII. died, and was succeeded in the papal see by Clement XIV.—no friend of the Jesuits, in consequence of which the differences between Portugal and the Vatican were soon made up. All this time P. was laboring energetically to improve the cultivation of the land and the system of education. In 1770, he was created Marquis of P., and from this period to the death of the king in 1777, he was at the very height of his greatness. The accession of Joseph's daughter, Maria I.—an enemy of the minister—was immediately marked by his downfall. He was deprived of his offices; the conspirators whom he kept in prison were released; many of his institutions were abolished; and he himself was only saved from the scaffold because he held in his possession documentary proofs of the former treason of his now triumphant enemies. Maria ordered him to retire to his castle of Pombal, where he died, 8th May 1782. The peasantry always spoke of him as 'The Great Marquis,' and history has stamped the rustic verdict with its approval. When he was turned out of office, he left the queen a public purse containing 78,000,000 cruzados, and a well-ordered and flourishing state.

POME (Lat. *pomum*, an apple), a form of fruit of which examples are found in the apple, pear, and other fruits of the *Pomaceæ*; and in which the *epicarp* and *mesocarp* (see FRUIT) form a thick fleshy mass; whilst the *endocarp* is scaly, horny, or stony, and divided into separate cells, in which the seeds are enclosed.

The fruit is crowned with remains of the calycine segments. Pomes have 1—5 cells, or spuriously 10 cells.

POMEGRANATE (*Punica granatum*), a fruit much cultivated in warm countries, and apparently a native of the warmer temperate parts of Asia, perhaps also of the north of Africa. It has been cultivated in Asia from the most ancient times, and is frequently mentioned in the Old Testament. It has long been naturalized in the south of Europe. In a wild state, the plant is a thorny bush, in cultivation it is a low tree, with twiggy branches, flowers at the extremities of the branches, the calyx red, the petals scarlet. It is generally referred to the natural order *Myrtaceæ*. The calyx is leathery, tubular, 5—7-cleft; there are 5—7

Section of a Pomegranate.

crumpled petals; the fruit is as large as a large orange, with a thick leathery rind of a fine golden yellow, with a rosy tinge on one side, not bursting when ripe; the cells filled with numerous seeds, each of which is surrounded with pulp, and separately enclosed in a thin membrane, so that the P. appears to be formed of a great number of reddish berries packed together and compressed into irregular angular forms. The pulp is sweet, sometimes subacid, and of a pleasant delicate flavor, very cooling, and particularly grateful in warm climates. It is often used for the preparation of cooling drinks. A kind of P. without seeds is cultivated and much prized in India and Persia. Pomegranates have long been imported in small quantities into Britain from Portugal and the north of Africa; but have never become an article of general demand and commercial importance like oranges. There is an ornamental variety of the P. with double flowers. The rind of the fruit is very astringent, and a decoction is used as a gargle in relaxed sore throat, and as a medicine in diarrhoea, dysentery, &c. Deriving its astringency from tannin, it is used to tan leather. The finest Morocco leather is said to be tanned with it, and small quantities are imported into Britain from the north of Africa for the preparation of the finest kinds of leather, under the name of *Pomegranate Bark*.—The bark of the roots is used as an anthelmintic, and is often successfully administered in cases of tape-worm. Its value was known to the ancients, and it has long been in use in India.—The P. tree is occasionally cultivated in hothouses or greenhouses in Britain. It bears the winters of the south of England in the open air, and is very ornamental, but the fruit is worthless. In some parts of the south of Europe it is used as a hedge-plant.

POMEL, a boss or ball used as an ornament on the top of pointed roof, turret, &c.

POMERANIA (Ger. *Pommern*), a province of Prussia, bounded N. by the Baltic, E. by West Prussia, S. by Brandenburg, and W. by the Mecklenburg duchies. Area, 11,600 square miles. Pop. (at the close of 1880) 1,540,034. P. is divided into the three governmental districts of Stettin, Stralsund and Köslin.

This province, which is one of the lowest and flattest in Germany, and has few hills of even moderate height, is intersected by the Oder (q. v.), which forms numerous lakes and ponds, the largest of which is the Dammer Lake. The waters of this lake and of the Oder are then carried into the Stettiner Haff, from which three outlets—those of the Peene, Swine, and Dievenow—lead into the Baltic. Between these three outlets are the two islands of Usedom and Wollin. After the Oder, the chief rivers of P. are the Ihna, Rega, Persante, Wipper, and Stolpe. The shores in some parts are protected by dikes and sand-banks. The soil is generally sandy, and in many districts even stony, although near Pyritz and Stargard, on the Ploen and Maduc Lakes, and at some points of the sea-coast, it presents a tolerably fruitful character, yielding good crops of wheat, and affording rich pasture. About half of the whole area is cultivated; about a sixth is uncultivated, or under water; and the remainder is in pastures, heath, and wood. The chief vegetable products, most of which are grown in sufficient quantities to be largely exported, are—rye, wheat and other grain, flax, hemp, tobacco, and timber. Among the other exports of P. are horses, cattle, sheep, swine, geese of superior quality, feathers, butter, wool, hams, sausages,

smoked poultry, &c. The sturgeon and salmon fisheries are very productive, and P. is noted for its admirable lampreys, eels, and crayfish, which are largely exported in a pickled state. The mineral products, which are inconsiderable, include bog-iron, lime, marl, alum, salt, amber found on the coast near Stolpe, and peat—which latter substance is obtained in enormous quantities, and extensively used for fuel, notwithstanding the abundant supply of wood yielded by the extensive and productive forests.

Linen and wollen fabrics, and leather, rank among the best of the industrial products; but the manufactures of P. are not of much importance. The principal branches of industry are agriculture, and the rearing of horses and cattle, while the active transport-trade between the neighboring Prussian states and the Baltic ports constitutes a very important source of wealth to the province. The main seat of Pomeranian trade is at Stettin (q. v.), which ranks as one of the most important commercial cities of Prussia.

P., like every other part of the Prussian dominions, is well provided with educational institutions, and, besides the university at Greifswald, it has 13 gymnasia, several normal and training schools, and numerous classical and other schools.

P. formed, in the earliest periods of its history, a part of the ancient kingdom of the Wends or Vandals. From the year 1062 it had its own ducal rulers, and from the beginning of the 12th c. it adopted Christianity in consequence of the preaching of Bishop Otto of Bamberg. Bogislaus XIV., who died in 1637, was the last male representative of the Wendish ducal line; and, on his death, the House of Brandenburg laid claim to the whole of the Pomeranian territories, in conformity with a compact which the latter family asserted to have been made between them and the Wendish dukes; but the country having been occupied by the Swedes during the Thirty Years' War, Prussia was obliged to content itself with the possession of Further P., or *Hinterpommern*, which was assigned to it at the Peace of Westphalia, while Sweden retained the remainder of P., with the island of Rugen (q. v.). After the death of Charles XII., and the subsequent decline of the Swedish power, Prussia was able to make good her asserted claims on the territory of P. at the Peace of Stockholm; and in 1720 Sweden was compelled to cede Southern P. and the island of Rugen, retaining only a narrow strip of land between Mecklenburg and the Baltic, which was also incorporated with Prussia in 1815, after having been first transferred by Sweden to Denmark as part indemnification for the separation from the latter kingdom of Norway, and subsequently ceded to Prussia by the Danes in exchange for the duchy of Lauenburg, and on the payment of 2½ million thalers to the latter, and of 3½ million thalers to the Swedish government.

POMMETTÉE, or **POMEL CROSS** in Heraldry, a cross whose extremities terminate in single knobs or pomels, like the *Bourdon* or pilgrim's staff.

Pommettée Cross.

POMO'LOGY (Lat. *pomum*, a fruit of any kind, an apple), a term much employed in France and Germany, and to a smaller extent in Britain, to designate the study of fruits and of their cultivation, particularly those of the natural order *Pomaceæ* (q. v.). See **FRUIT**, **FRUIT-GARDEN**, **APPLE**, **PEAR**, &c.

POMONA (whose name is obviously connected with *pomum*, 'a fruit') was, among the Latins, the patron divinity of garden-produce. The poets, not, perhaps, without some allegorical design, represent several of the rural gods as her lovers—Sylvanus, Picus, Vertumnus, &c. Of Vertumnus, in particular, it is related that after he had vainly tried to approach her under a thousand different forms, he at last succeeded by assuming the figure of an old woman. In this guise, he recounted to her the lamentable histories of women who had despised love, and having touched her heart, suddenly transformed himself into a blooming youth and married her. But Vertumnus (connected with *verto*, 'to turn,' or 'to transform') is probably nothing more than a personification of those changes by which plants advance from blossom to fruit. The worship of P., as was natural among a homely race of farmers and shepherds like the ancient Latins was of considerable importance. Varro tells us that at Rome her services were under the care of a special priest, the *flamen Pomonalis*. In works of art she was generally represented with fruits in her lap, or in a basket, with a garland of fruits in her hair, and a pruning-knife in her right hand.

POMONA, or **MAINLAND**, much the largest and most populous of the Orkney Islands (q. v.), in which group it occupies a central position. It is open to the Atlantic on the west, and to the German Ocean on the east, while on the north Ennallow and Shapinsha Sounds separate it from the islands of Ronsay and Shapinsha, and on the south, Scapa Flow separates it from Hoy and South Ronaldsha. Area, 150 square miles; pop. (1881) 17,165. It is 25 miles in length, and 15 miles in extreme breadth, but is very irregular in shape. At the town of Kirkwall, the breadth of

the island is only about two miles. In the west, the shores are bold and elevated, but there is a general slope towards the east. The surface is diversified with hill and lake, and consists in great part of moor and heath. Good pastures are found, however, and in the valleys there is a fertile, loamy soil. Oats, beans, and cereals are produced, and sheep and swine are extensively reared. The chief towns are Kirkwall (q. v.) and Stromness (q. v.).

POMPADOUR (JEANNE ANTOINETTE Poisson), MARQUISE DE, a notable mistress of Louis XV., was born in Paris in 1720 or 1722. Her reputed father was a certain François Poisson, who held a humble office in the army-commissariat; but M. le Normand de Tournheim, a rich *fermier-général*, claimed for himself the honors of a dubious paternity, and brought up the little Jeanne as his daughter. She turned out a wonderfully clever child, and M. le Normand spared no pains to give her the best, or, at least, the most stylish education possible. She excelled in such accomplishments as music, elocution, and drawing; but what charmed the brilliant society that frequented the *salons* of the rich financier, was the perfect grace and beauty of her figure, and the exquisite art with which she dressed. A crowd of suitors constantly besieged her, but the one who obtained her hand was her cousin, Le Normay l'Étioles. They were married in 1741. But Madame l'Étioles, who was constantly told by her infamous mother that she was 'a morsel for a king,' was careless of her husband's honor and peace. Though he loved her to distraction—and he was a man with whose love any woman might have been content—she, cold, heartless, and ambitious, was scheming day and night to attract the notice of the monarch. Her efforts were after a time crowned with success, and Madame l'Étioles was installed in the palace of Versailles; she was soon afterwards ennobled by the title of Marquise de P., and long ruled the king, first as mistress, and afterwards as *amie nécessaire*.

One reads with some astonishment of the incessant artifices she had recourse to in order to preserve her influence—the everlasting huntings, concerts, private theatricals, little suppers, and what not—anything to distract the royal mind (surely sufficiently distracted already by nature), and to make it think only of the clever purveyor of gaities! The private theatricals in particular were a great success, and were 'got up' every winter from 1747 to 1753—the marquise herself proving a charming actress. The king thought the marquise extremely clever, and, when he ceased to 'love' her, was glad to avail himself of her services as his political adviser. In fact, she became premier of France; the council of ministers assembled in her boudoir, where the most important affairs of state were settled. The choice of ministers, of ambassadors, of generals, depended on the caprice of a female; the Abbé de Bernis, the favorite of a favorite, entered the council. Foreign diplomacy turned the circumstance to account. The Austrian prime-minister induced Maria Theresa, to sacrifice pride to the exigencies of her position, and the empress-queen wrote the courtesan a letter in which she addressed her as *ma cousine*. That word turned the head of the marquise, and changed for a time the foreign policy of France. She died (15th April 1764) with the reins of government in her hands. During her lifetime, immense sums from the national treasury were paid away to the marquise, and to her brother, created Marquis de Marigny. In the years 1762—1763 alone, they amounted to 3,456,000 livres. She had numerous houses and lands also given her. In 1853, M. le Roi, keeper of the town-library of Versailles, published in the *Journal de l'Instruction Publique*, a list of the expenses of the Marquise de P. during the years in which she had enjoyed the royal favor, which he had found in MS. in the archives of the department of Seine-et-Oise. They amounted to 86,000,000 livres. She was imperious and vindictive beyond measure, and with relentless cruelty doomed to perpetual imprisonment, in the dungeons of the Bastille and elsewhere, multitudes who had dared to speak about her ill-gotten gains and power. After facts like these it is but a poor apology for the marquise to say that she encouraged savans, poets, and philosophers, patronized and protected the *Encyclopédie*, and aided in the expulsion of the Jesuits. The *Lettres* in her name are mostly spurious. See the *Life* by Goncourt (new ed. 1878).

POMPEII, a city of Campania, was built at the mouth of the river Sarnus (*Sarno*), looking out on the Bay of Naples. It stood at the base of Mount Vesuvius, between Herculaneum and Stabiae. Of its early history little is known (legend ascribed its foundation to Hercules); but in more recent times it became a favorite resort for wealthy Romans, many of whom, including Cicero, had villas in the suburbs. It must have been at one time a place of considerable trade, since it was the port-town of Nola and other inland cities which studied the fertile valley of the Sarnus. The city was much damaged by an earthquake which happened on the 5th February 63 A.D., and not many years had revolved when the great and final calamity overtook it. In 79 A.D. occurred that terrific eruption of Vesuvius which, in one day, overwhelmed in irremediable ruin the towns of P., Herculaneum, and Stabiae. In

course of time a small village rose at or near the spot; but by and by the memory of P. was forgotten, and for centuries its very site was unknown. The difficulty of discovering its true position was increased in consequence of the changes produced by this fearful convulsion, which had hurled back the Sarnus from his ancient course, and raised the sea-beach to a considerable height, so that the rediscovered city, to which merchantmen resorted of old, is now a mile from the coast, and a considerable distance from the stream that in ancient times was wont to skirt its walls. For more than sixteen hundred years, P. lay undisturbed beneath heaps of ashes and cinders. At length, in 1689, some ruins were noticed, but it was not till 1755 that any excavations were made. These operations, begun by the Neapolitan government, have been continued till the present time (and recently with increased energy), and have been exceedingly productive of objects which interest the antiquarian and the classical scholar. The remains found are in a remarkably good state of preservation, owing to the fact that the city was destroyed not by lava, but by showers of sand, ashes, and cinders (*lapilli*), forming a light covering, which found its way into every nook, and, as it were, hermetically sealed up the town.

It would appear that in some parts at least the matter was deposited in a state of liquid mud, and so flowed into the remotest cellars of the doomed habitations. This is proved by the discovery of the skeleton of a woman 'enclosed in a mould of volcanic paste, which retained a perfect impression of her form.' It suggested to Signor Fiorelli, the director of the excavations, the idea of filling up the moulds with liquid plaster, and obtaining casts of the forms they contained. Many interesting objects recently discovered have thus been preserved. Among recent excavations are several paintings of classical subjects, one of which, the Laocöon, excavated in 1875, is a most valuable specimen of ancient art. That the superincumbent rubbish, in most places about 15 feet deep, is the accumulation of several eruptions is proved by the facts: that as many as eight or nine different layers have been distinctly counted; and that, while the upper layers are undisturbed, the lower one has evidently been moved. The comparatively few skeletons found, and the almost entire absence of objects of great value, as gold and silver plate, show that most of the inhabitants (estimated at 20,000) escaped and returned to bury their dead, and recover their treasures. In the autumn of 1864, upwards of two hundred skeletons were found in a temple of Juno, the victims having evidently gone thither to seek the protection of the goddess. Only about one-third of the city has as yet been excavated. The plan of P. seems to have been regular, the narrow streets crossing one another at right angles. The houses were plain and seldom more than two stories high, and had all their good apartments on the ground-floor. The walls are about two miles in circumference. It would be impossible in our brief space to attempt even an enumeration of the objects discovered in this now famous city.

Suffice it to say that in all the departments of social life—in the affairs of domestic and public life, of the worship of the gods, and the shows of the arena—in architecture, painting, and sculpture—in fine, in all the appliances of comfort and of luxury in a wealthy community, we have, as it were, a living picture of a city 1800 years ago. The reader who wishes fuller information should consult Mazois' work, *Les Ruines de Pompeii* (Paris, 1812—1838); Breton's *Pompeia* (Paris, 1855); Overbeck's *Pompeii* (3d ed. 1875); Gell's *Pompeiana* (4 vols. 1824—1830); *Something of Italy*, by W. Chambers (1862); and *Pompeii*, by T. H. Dyer (1875). In connection with the celebration of the 18th centenary of the destruction of the city, a volume was issued in 1879 by the directorate of the Museum of Naples, treating of every aspect of the public and private life of the people of Pompeii.

POMPELMOOSE, or **POMELO** (*Citrus pomelo*), a fruit nearly resembling the Shaddock (q. v.), of which, perhaps, it ought to be esteemed a variety, although it is now distinguished by some botanists as a separate species. It is large and pale yellow. It has long been cultivated in the East Indies, and has recently been introduced into many warm countries. It has become an article of importation into Britain, and is frequently to be seen in fruit-shops. In pleasantness of taste, it resembles the best oranges. It is often preserved with wine and sugar, when it is very agreeable and refreshing in a hot climate. The rind is often candied.

POMPEY THE GREAT. Cneius Pompeius Magnus, son of Cn. Pompeius Strabo, was born in 106 B.C. At the early age of 17 he began to learn the military art under his father by service in the field against the Italians in the Social War. Though so young, he gave proof of extraordinary valor, and of remarkable energy of character. On the death of his father in 87 B.C., when he was only 19 years of age, he was left without a protector, and during the temporary triumph of the Marian party, he was for some time in considerable danger.

When Sulla, to whose side he was attached, returned from

Greece to Italy to oppose Marius, P. hastened into Picenum, where he had considerable estates and influence, and there raised an army of three legions, with which he successfully opposed the forces of the Marian party, compelling them to quit the district, and effecting a junction with Sulla. During the rest of the war he behaved with great prudence and valor, and with such remarkable success, that, on the restoration of peace in Italy, the conduct of the war against the remains of the Marian faction in Africa and Sicily was intrusted to him. He speedily performed his commission, and on his return to Rome was honored with the name of MAGNUS (i. e., 'The Great'), and with a triumph, which, for one who had not yet held any public office, and was merely an *eques*, was an unprecedented distinction. His next exploits were the reduction of the followers of Lepidus, whom he drove out of Italy, and the extinction of the Marian party in Spain, led on by the brave Sertorius. This latter work was one of no small difficulty. P. suffered some severe defeats at the hands of Sertorius, and it was only after Sertorius had been assassinated that he was able to put an end to the war. In returning to Italy after an absence of five or six years in Spain, he fell in with and defeated the remnants of the army of Spartacus, and thus claimed the credit of concluding the Servile War. He was now the idol of the people, and though legally ineligible to the consulship, was elected to that important office, for the year 70, the senate relieving him of his disabilities rather than provoke him to extremities. Hitherto P. had belonged to the aristocratic party, but as he had of late years been looked upon with suspicion by some of the leading men, he publicly espoused the people's cause. He carried a law restoring the tribunician power to the people; and aided largely in introducing the bill of Aurelius Cotta (*Lex Aurelia*), that the *judices* should for the future be taken from the *senate*, the *equites*, and the *tribuni aerarii*, instead of from the senate alone.

In 67—66 B.C., P. performed a noble service to the republic in clearing the Mediterranean of the pirates who infested it in immense numbers, and during the next four years, 65—62, he conquered Mithridates, king of Pontus, Tigranes, king of Armenia, and Antiochus, king of Syria. At the same time he subdued the Jewish nation, and captured Jerusalem. On his return to Italy he disbanded his army, and entered Rome in triumph for the third time in 61 B.C. And now his star began to dim. Henceforward we find him distrusted by the aristocracy, and second to Cæsar in popular favor. After his return, he was anxious that his acts in Asia should be ratified by the senate, and certain lands apportioned among his veteran soldiers. But the senate declined to accede to his wish, and he therefore formed a close intimacy with Cæsar, who promised to secure for him the accomplishment of his objects, if he in turn would assist Cæsar in the attainment of his aims. Crassus, who possessed enormous wealth, and who in consequence exercised a wide influence at Rome, was induced to forego his grudge to P., and thus these three men formed among themselves that coalition which is commonly called 'the First Triumvirate,' and which for a time frustrated all the efforts of the aristocratic party. This small oligarchy carried all before them; P.'s acts in Asia were ratified; Cæsar's designs were all gained; his agrarian law, distributing land in Campania among the poorer citizens was passed, and thus, too, P.'s promises to his troops were fulfilled. Cæsar's daughter, Julia, was given in marriage to P., and private relationship was thus made to bind tighter the tie of political interest.

And now, for some years following, Cæsar was reaping laurels in Gaul, and rising higher in popular esteem as a warrior and statesman, while P. was idly wasting his time and his energies at Rome. But P. could not bear a rival. Jealousies sprang up; Julia died in 54 B.C., and thus father-in-law and son-in-law were sundered by a yet wider gulf, which no bridge could span. P. now returned to his former friends, the aristocracy, whose great desire was to check Cæsar's views, and strip him of his command. Cæsar was ordered to lay down his office and return to Rome, which he consented to do, provided P., who had an army near Rome, would do the same. The senate insisted on an unconditional resignation, and ordered him to disband his army by a certain day, otherwise he would be declared a public enemy. To this resolution two of the tribunes in vain objected; they therefore left the city and cast themselves on Cæsar for protection. It was on this memorable occasion that he crossed the Rubicon, and thus defied the senate and its armies, which were under P.'s command. The events of the civil war which followed have been recorded in the life of Cæsar (q. v.). It remains only to mention, that after being finally defeated at Pharsalia in 48 B.C., P. escaped to Egypt, where according to the order of the king's ministers, he was treacherously murdered by a former centurion of his own, as he was landing from the boat. His head was cut off, and afterwards presented to Cæsar on his arrival in Egypt. But Cæsar was too magnanimous to delight in such a sight. The murderer of P. was, by his orders, put to death. The body lay on the beach for some time, but was at length buried by a

freedman, Philippus, who had accompanied his master to the shore.

POMPEY'S PILLAR. The name of a celebrated column standing in the neighborhood of Alexandria. It stands upon an eminence about 1800 feet south of the walls. It is a monolith of red granite, and of the Corinthian order, and stands upon a pedestal. Its total height is 98 feet 9 inches; shaft, 73 feet; 29 feet 8 inches in circumference. The shaft is well executed. On the summit is a circular depression for the base of a statue, which in some old drawings is represented standing on it. The name popularly applied to it of Pompey's pillar is an erroneous appellation given by ancient travelers, who confess they do not know whence it was derived, and still retained. The inscription, on the base, however, shows that it was erected by Publius, prefect of Egypt, in honor of the Emperor Diocletian, who is styled upon it 'the invincible;' and it is supposed to record the conquest of Alexandria by Diocletian, 296 A.D., and the suppression of the rebellion of the pretender Achilleus. It appears to have been in the vicinity of a circus, forum, or gymnasium. The obelisk stood upon some fragments of Egyptian monuments of remote antiquity, consisting of a piece with the name of a monarch of the 13th Egyptian dynasty, and another with that of Psammetichus I., the former of which is now in the British Museum.—Wilkinson's *Modern Egypt*, I. p. 149 and foll.; White, *Egyptiaca*, p. 1, and foll.; Champollion-Figeac, *L'Egypte*, p. 472; Norden, I. p. 22.

PONA'NI, or PANIANI, a seaport town of British India, in the district of Malabar, about 600 miles south-east from Bombay. The population is employed in fishing and in trade. Pop. 12,000.

PONCE DE LEON, FRAY LUIS, a celebrated Spanish poet, was born in 1527, probably at Granada. In 1544 he entered the order of St. Augustine at Salamanca, where he studied, took his degree in theology in 1560, and was appointed professor of the same in 1561. The reputation that he acquired as a learned commentator on the Bible induced some persons, who were envious of his success, to accuse him of having disregarded the prohibition of the church, inasmuch as, at the request of a friend, he made a new translation of the Song of Solomon, and brought out prominently, in his arrangement of the verses, the true character of the original—viz., that of a pastoral eclogue. This interpretation was not that adopted by the Catholic Church, and P. was summoned, in 1572, before the formidable tribunal of the Inquisition at Valladolid to answer the charges of Lutheranism, and of translating the sacred writings contrary to the decrees of the Council of Trent. The first accusation he quickly disposed of—for he had in reality no inclination to a foreign Protestantism; but the second was undoubtedly true, and P. was imprisoned. After five years he was released through the intervention of powerful friends, and was even reinstated in his chair at the university with the greatest marks of respect. The numerous auditory that assembled to witness the resumption of his lectures, were electrified when P. began with these simple words: 'As we observed in our last discourse'—thus sublimely ignoring the cause and the duration of his long absence from his lecture-room. In 1580, P. published a Latin commentary on the Song of Solomon, in which he explained the poem directly, symbolically, and mystically; and, therefore, as obscurely, says Mr. Ticknor, 'as the most orthodox could wish.'

P. lived 14 years after his restoration to liberty, but his terror of the Inquisition never quite left him, and he was very cautious in regard to what he gave to the world during his lifetime. He died in 1591. P.'s poetical reputation was wholly posthumous, for though his *De los Nombres de Christo* (on the names of Christ), (Salamanca, 1583—1585), and *La Perfecta Casada* (The Perfect Wife), (Salamanca, 1583), are full of imagery, eloquence, and enthusiasm, yet they are in prose. His poetical remains were first published by Quevedo at Madrid in 1631, under the title, *Obras Proprias, y Traducciones Latinas, Griegas y Italianas: con la Paraphrasi de Algunos Salmos y Capítulos de Job*, and have since been often reprinted. These consist of translations from Virgil's *Ecloques* and the *Georgics*; from the *Odes* of Horace, and other classical authors, and from the Psalms. His original poems are few, but they are considered among the most precious in the author's language, and have given P. a foremost place among the Spanish lyrists. According to Ticknor: 'Luis de León had the soul of a Hebrew, and his enthusiasm was almost always kindled by the reading of the Old Testament. Nevertheless, he preserved unaltered the national character. His best compositions are odes composed in the old Castilian versification, with a classic purity and a vigorous finish that Spanish poetry had never till then known, and to which it has with difficulty attained since.' See Nicolas Antonio, *Bibliotheca Hispana Nova*; Ticknor, *History of Spanish Literature*; and Villenain, *Essais sur la Poésie Lyrique*.

PONCHO, an important article of male attire in Chili. It consists of a piece of woollen cloth, 5—7 feet long, 3—4 feet broad, having in the middle a slit through which the wearer passes his

head, so that the poncho rests upon the shoulders and hangs down before and behind. In the fashions of recent times, the poncho has been introduced in Europe.

PONDICHE'RY, the chief of the French settlements in India, situated in the district of South Arcot, in the Madras Presidency. The other French establishments are Mahé in Malabar, Karikal (q. v.) in Tanjore, Yanam in Godavari, and Chandernagore (q. v.) in Bengal. The extent of the united territories is given by M. Block at 188 square miles. P. is situated on the Coromandel Coast in 11° 56' of N. lat., and 79° 54' of E. long., and is 88 miles from Madras. The territory of P. is divided into three districts—Pondicherry, Vellennore, and Bahour—has an area of 107 square miles, and comprises 92 villages. The total population of the French establishments in India in 1840 was reckoned at 171,217; in 1876, it amounted to 285,022. The population of the town of P. is about 50,000. Its exports (indigo, cotton, skins, nuts, oils, &c.) and imports amount in value to about £600,000 annually. Pop. of district of P. about 90,000. The town stands on a sandy plain, and is divided by a canal into a European and a native town. It has a handsome square, where are the governor-general's house, the Catholic cathedral, and the bazaar. In P. is the high court for the French possessions in Asia, a European college, and an Indian school. The open roadstead is defended by a citadel, and possesses a lighthouse; and from it mail steamers sail for Europe, Madras, &c. The governor of P. is governor-general of the French possessions in India. The spinning of cotton and the fabrication of cotton-thread are the chief manufactures in French establishments.

History.—The first settlement of the French in India was at Surat, in 1668. The chief of the French East India Company at that time was Carou. Subsequently, he took Trincomalee from the Dutch; but they were not long in repossessing themselves of it. Carou then turned to the Coromandel coast. In 1672, he took from the Dutch St. Thomé, a Portuguese town (now a suburb of Madras); but two years later, the Dutch retook this place also. It was then that François Martin collected about 60 Frenchmen and settled them in P., which, in 1674, he had purchased, with the surrounding territory, from Gingee, who had the supervision of all Sivaje's conquests in the country. The Dutch took the town in 1693; but by the treaty of Ryswick it was restored to the French in 1697. Chandernagore was ceded to the French in 1688 by Aurangzebe. In 1727, they obtained the cession of Mahé; in 1739, they purchased Karikal from the king of Tanjore; and in 1752, Yanam was ceded to them. Duplex was governor of P. when war broke out between France and England; and in 1746 La Bourdonnais took Madras. In 1748, Admiral Boscawen besieged P., but two months later, was compelled to raise the siege. In the same year occurred the peace of Aix la Chapelle; but it did not put an end to hostilities in India till some time later. In 1757, war recommenced. In 1758, Count de Lally became governor-general, and attacked the English settlement of Fort St. David, which surrendered, and was totally destroyed. In 1761, Eyre Coote took Pondicherry. By the peace of Paris, P. was restored to the French in 1763 with reduced territory, and also Mahé, Karikal, and Chandernagore. P. was again taken by the English under Sir Hector Monro in 1778, and restored in 1783. In 1793, the English again repossessed themselves of it, but the treaty of Amiens in 1802 again restored it, but only till the following year. From this time it was held by the English till, by the treaties of 1814 and 1815, it was for the last time restored to France, reduced to the narrow limits assigned by the treaty of 1783.

Annexed is a statement exhibiting some particulars relative to such of the present French possessions in India subordinate to P. as are not noticed separately in this work.

YANAM, in the Godavari District, in 16° 43' N. lat., and 83° 11' 16" E. long., about 24 miles south of Rajahmundry. The area is about 13 square miles.

MAHE, in the Malabar District, in 11° 42' N. lat., and 75° 33' 16" E. long. The area is only about 2½ square miles.

PONDWEED (*Potamogeton*), a genus of plants of the natural order *Najas*, having hermaphrodite flowers, sessile upon a spike or spadix, which issues from a sheathing bract or spathe, a perianth of four scales, four sessile anthers opposite to the scales of the perianth, four pistils, which become four small nuts, and a curved embryo. The species abound chiefly in the rivers, lakes, and ditches of Britain and continental Europe, but they are found also in other parts of the world, and some of them in New Holland. They often present a beautiful appearance in clear streams and ponds, where they protect the spawn of fish and harbor aquatic insects, their seeds also affording food to aquatic birds. The roots are a favorite food of swans. Some of the species have the leaves all submersed, others have some of their leaves floating, and considerably different in form from the submersed leaves.

PO'NGO (*Simia* or *Pithecus Wormii*), an ape of the same genus with the Orang (q. v.), but of much larger size, six feet or more

from the heel to the crown of the head, and covered with black hair, with which dark red hair is mingled. It is a native of Borneo, Sumatra, and probably of other neighboring islands, inhabiting the deepest recesses of the forests, and much more rarely seen by man than its congener the orang, which was at one time supposed by the most eminent naturalists to be the same species in a younger state. It is sometimes called the Black Orang. It has a very prominent muzzle, a large mouth, the face nearly naked, except the lower part, which has a beard. Little is yet known of the habits of the pongo. It is believed to feed chiefly on fruits.

It possesses great strength, and like the orang, is evidently adapted by its conformation for moving chiefly among the boughs of trees.

PONIATOWSKI, a celebrated princely family of Poland, is of Italian origin, being directly descended from the family of the Torelli, whose ancestors were Counts of Guastalla. One of the Torelli family having settled in Poland, assumed the name of P. from his wife's estate of Poniatow in that country. Those of the P. family, who make a figure in history are PRINCE STANISLAS P., who, in the war of succession to the kingdom of Poland, joined Charles XII. of Sweden in supporting Stanislas Leszczynski; his sons, STANISLAS-AUGUSTUS, the last king of Poland (q. v.), and ANDREW, who rose to great distinction in the Austrian service; and Andrew's son, JOSEPH-ANTONY, PRINCE P., the celebrated Polish chief in the army of Napoleon. Joseph-Antony was born at Warsaw, 7th May 1762, and at the age of 16 entered the Austrian army, with which he made the Turkish campaign of 1787, and rose to the rank of colonel of dragoons. In 1789, he returned to Poland, and was named commander-in-chief of the army of the south, having under him Kosciuszko, Wielhorski, Lubomirski, and other celebrated leaders. His army, though much inferior in numbers to that of Russia, which, in 1792, invaded the country, gained the brilliant victories of Polonné and Zieloné; but P.'s uncle, King Stanislas, by agreeing to the convention of Targowitz (q. v.), put an end to the contest in 1793. The prince then resigned his command, and went into voluntary exile, but returned in the following year to aid Kosciuszko, now dictator, in his fruitless opposition to the third partition of Poland. On the proposal of Napoleon to reconstitute the kingdom of Poland, P. joined the French (1800) at the head of a Polish army, and did good service against the Russians at the battles of Golymin, Danzig, and Friedland; but the French emperor, by the treaty of Tilsit, handed over Poland to its enemies, and only the duchy of Warsaw (nominally subject to the king of Saxony) was left intact.

P. was appointed generalissimo and commander-in-chief of the duchy; and so zealously did he labor for the development of its military resources, that, in 1809, when the war between France and Austria was resumed, he was able to drive the Austrians out of the Polish territory, and overrun a considerable part of Galicia. He continued to administer the military affairs of the duchy till 1812, when he joined the French army, destined to invade Russia, with a Polish army of 100,000 men. But to his intense disgust, the greater part of his army was broken up into detachments, which were incorporated with the various French legions, and P. was left with not more than 30,000 men under his direct command. At the head of this division, which always composed the extreme right of the French army, P. gathered innumerable laurels on the battle-field, and at the storming of the Russian fortresses; but he was so severely injured at Smolensko during the retreat, that he was obliged to return to Warsaw (December 1812). In the following autumn, he resumed his old place in the French army, and on October 16, received from the emperor the dignity of Marshal of France, an honor, in his own estimation, much inferior to that of 'generalissimo of the Poles,' which he already possessed. After the defeat at Leipzig (q. v.), P. was left with the remnant of his Polish division to protect the French retreat, which he accomplished by keeping the Prussians in check for several hours; at last, when his force was reduced to 300 men with 30 horses, and himself severely wounded, he retreated over the Pleisse, swimming his horse through the river; but in attempting similarly to cross the Elster, exhausted nature could no longer bear up, and he sank to rise no more, October 19, 1813. His body was recovered six days after, and was embalmed and carried to Warsaw, whence it was afterwards removed to Cracow, and placed beside the ashes of Sobieski and Kosciuszko.

PONI-A-MOUSSON, a town of France, department of Meurthe-et-Moselle, on the railway from Nancy to Metz, 20 m. N.-N.-W. of the former of these towns. The Moselle flows through the town, which is situated in a fruitful valley. There is a fine Gothic church dedicated to St. Martin. P. has large cavalry barracks, and some manufactures of pottery. Pop. (1876) 9904. It was the birthplace of Marshal Duroc, the favorite and friend of Napoleon.

PONTCHARTRAIN, LAKE, in Louisiana, U. S. America, about 5 miles north of New Orleans, with which it communicates

by a canal, is 40 miles long, and 24 miles in extreme width. It is navigated by small steamers, and communicates on the east with the Gulf of Mexico, and on the south with the Mississippi. Its greatest depth is from 16 to 20 feet.

PONTECORVO, a city of southern Italy in the province of Caserta, situated on the river Garigliano, 37 m. north-west of Capua, with 10,020 inhabitants, almost all engaged in agriculture. It has an old castle, many churches, and is a bishopric. It formerly belonged to the pope; but now, since 1860, it forms part of the kingdom of Italy, and is a sub-prefecture. Napoleon I. gave the title of Prince of Pontecorvo to Marshal Bernadotte, afterwards king of Sweden.

PONTÉ DELGA'DA, a town on the south coast of the island of St. Michael, one of the Azores (q. v.), in lat. 37° 40' N., and long 25° 36' W. It is defended by the Castle of St. Braz, which can mount 90 pieces of cannon, and by the forts of Sao Pedro and Rosto de Cao. The anchorage in the roadstead is bad and the harbor is shallow, but still the trade (which is largely in the hands of English merchants) is the most considerable of all the towns in the Azores. The chief exports are wheat, maize, and oranges. Pop. at census of 1878, 17,940.

PONTEFRAC (commonly pronounced *Po'mfret*), a market-town and municipal and parliamentary borough, in the county of York, and 24 miles south-west of the city of that name, on the Lancashire and Yorkshire Railway. There are two churches, viz., St. Giles and All-Saints, the latter is in the Early English style, and has a handsome tower. There are a grammar, as well as national and other schools, several almshouses, a large workhouse built in 1864, a splendid market hall opened by Lord Palmerston in 1860, &c. In the vicinity are extensive gardens and nurseries. Eight fairs for the sale of cattle take place annually. The trade is chiefly in corn, liquorice, and malt. Two members are returned to the House of Commons for the borough. Pop. of mun. bor. (1871), 6432; (1881) 8798; of parl. bor. (1871), 11,653; (1881) 15,329.

The castle of P., built shortly after the Conquest, was a large and strong edifice, and stood on a commanding height. It was the scene of the imprisonment and death of Richard II., and here also Rivers, Grey, and Vaughan were put to death, at the instigation of Richard III. The remains of the castle to be seen at the present day are very meagre.

PONTEFRAC **CAKES** are small lozenges of refined liquorice, which have for centuries been made at Pontefract, and are much esteemed. They are impressed with a rude figure of a castle, intended to represent Pontefract Castle.

PONTEVEDRA, a town of Spain, in Galicia, is situated on a peninsula slope near the mouth of the river Lerez, 35 miles south of Santiago. P. is a clean and pretty place, with high old walls, granite-built houses, broad streets, and pleasant arcades. It takes its name from the bridge (*Pons Vetus*) that spans the river. The Pontevedrans are engaged chiefly in agriculture, though sea-fishing is also carried on, and there are some manufactures. Pop. 4800. The neighborhood, of which charming views are obtained from parts of the town, is covered with villas, farms, and woodlands.

PONTIANA'K, the capital of the kingdom of the same name on the west coast of Borneo, is situated near the junction of the Landak and Kapuas. It is built on both banks of the river, which is 900 feet broad, and thence to the sea is called the Pontianak. The city derives its importance from being the seat of the Netherlands' Resident, who rules directly and indirectly over the whole west coast, from 2° 56' S.—2° 50' N. lat., and 108° 45'—112° 50' E. long.; territories rich in vegetable and mineral wealth. The Residency House is near Fort Du Bus, in 0° 2' N. lat., and 109° 1' 30' E. long.; other principal buildings being the sultan's palace, the mosque, and hospital. Pop. 7000, including 2000 Chinese. Trade is the only pursuit in the town; and the rich alluvial lands are partly cultivated with rice, sugar-canes, cotton, indigo, coffee provisions, and fruits.

Besides a number of small dependencies, the Netherlands' Resident at P. governs the important kingdoms of Landak, Mampawa, and Sambas, with the mining district of Montrado, in the north; Tayang, Simpang, and Matan or Succadana, to the south; and Sangouw, Sekadouw, and Sintang, in the interior. The produce consists of diamonds, gold, coal, tin, iron, wax, edible nests, pepper, gutta-percha, &c. There are many gold mines in Montrado and other districts; rich iron ores in Matan; gold, platina, copper, &c., in Sambas; and in former times, Landak was rich in diamonds, but the produce is now trifling. In this district was found the famed diamond of the Sultan of Matan, which weighed 367 carats. The annual produce of the mines in the Residency of P. is estimated at not less than 425,000 ounces of gold. The population is about 400,000, of whom 250,000 are Dyaks, 90,000 Malays, 25,000 Chinese, and some 150 are Europeans.

The Dutch imports and exports have each a value of something

less than £200,000 a year. There are about 70 vessels above 10 tons burden belonging to the west division of Borneo, with a tonnage of about 1700 tons. The other Netherlands possessions in Borneo are called the Residency of the South and East Division, including the lands from Matan, in the south-west, along the south and east coasts to 0° 50' N. lat. The Resident's house is at Banjerassin, on the island of Tatas, 15 miles from the mouth of the Banjar, in 3° 34' 40" S. lat., and 114° 30' E. long. Pop. 30,000. The exports are—pepper, diamonds, gold-dust, coal, benzoin, wax, rattans, dragon's-blood, camphor, edible nests, iron, fire-arms, &c. Imports—piece-goods, powder, knives, opium, rice, salt, sugar, Chinese porcelain, silk-stuffs, coral, pearls, &c. In one year the coal-mines of Orange-Nassau produced 3650 tons. On the east coast there is also coal, and the Sultan of Kutei delivers it, according to contract, for the use of the Dutch navy, at £1 per ton. The imports of the South and East Residency have an annual value of £250,000, and the exports of £125,000. The vessels above 10 tons belonging to it are about 30, with a tonnage of 2500 tons. At Nagara (pop. 10,000), in Banjerassin, are important factories of fire-arms and other weapons.

There has been constant war on the south and east coasts since 1859. In 1860, the direct government of Banjerassin was assumed by the Resident, but the interior of the kingdom has always been disturbed, and especially in 1873, through the war with Atcheen (q. v.) inciting the Mohammedan population against the Dutch. In 1873, pop. of the south and east division, 869,763, of whom 403 were Europeans, and 2643 Chinese.—See *Borneo's Westerafdeeling, Geographisch, Statistisch, Historisch* (P. J. Veth, Amsterdam); the latest Colonial Reports by the Netherlands Secretary of State for the Colonies, &c.

PO'NTIFEX (of doubtful derivation) was the title borne by the members of one of the two great colleges among the ancient Romans, instituted for the purpose of preserving and cultivating religious knowledge; the other was the college of Augurs. See **AUGURIES** and **AUSPICES**. It is customary to speak of the college of pontiffs as a 'priesthood;' it was not, however, strictly speaking, such—that is to say, the members were not charged with the worship of any particular divinity, nor did they conduct sacrifices. Their duties embraced the regulation of all the religious rites and ceremonies (both public and private) of a state—e. g., how the gods should be worshiped, how burials should be conducted, how the souls of the dead (manes) should be appeased. To them was entrusted the care of the calendar, the proclamation of festival days, &c. They also saw that every religious and every judicial act took place on the right day. 'As they had thus,' says Dr. Mommsen, 'an especial supervision of all religious observances, it was to them in case of need (as on occasion of marriage, testament, or *arrogatio*) that the preliminary question was addressed, whether the matter proposed did not, in any respect, offend against divine law.' In matters of religion, they were the supreme authorities; from their decisions there was no appeal, and they themselves were responsible neither to the senate nor the people; further, they had power to inflict punishment on such priests as dared to disobey their injunctions, and deviate into schismatical courses. The words of Festus are: *rerum quæ ad sacra et religiones pertinent, IUDICES ET VINDICES*. Their president was termed *pontifex maximus*.

The pontiffs, according to Roman tradition, were instituted by Numa—a mythical person, to whom the origin of nearly all the religious institutions of Rome is ascribed. But as they appear in all the Latin communities, they are regarded by Mommsen as a 'thoroughly national Italian institution,' and probably found a place in the earliest religious organization of the Latin race. Their number was originally four, or, including the *pontifex maximus*, five, all of whom were taken from the patricians. In 300 B.C., the Ogulnian Law raised the number to nine, four of whom were to be plebeians. The first plebeian, however, who attained the dignity of *pontifex maximus* was Tib. Coruncanus, 254 B.C. Sulla, in 81 B.C., again increased the number to 15, and Julius Cæsar to 16. During the empire, the functions of *pontifex maximus* were generally discharged by the emperors themselves; and the name survived even the establishment of Christianity, occurring in inscriptions of Valentinian, Valens, and Gratianus; but at length the emperors dropped it, when it was picked up by the Christian bishops of Rome; and now this title, borrowed from a pagan cult, forms one of the sacred designations of His Holiness the Pope.

PONTIFICAL (Lat. *pontificalis*, belonging to a pontiff or bishop), one of the service-books of the Church of Rome, in which are contained the several services, whether in the administration of sacraments, or the performance of public worship, in which the bishop exclusively, or at least a priest delegated by the bishop, officiates. There were many such collections for the various national churches; but that which is now in universal use throughout the Western Church is the *Pontificale Romanum*, or Roman Pontifical, as published by authority of Clement VIII. in 1596,

and repeatedly republished since that time. The P. contains the services for ordinations, for religious professions and receptions of monks and nuns, consecrations, benedictions, &c., as well as of the solemn administration by a bishop of those sacraments which are ordinarily administered by priests. Besides the prayers to be recited, the P. also lays down the ceremonial to be observed. The rules of this ceremonial are of two kinds—*preceptive*, the literal observance of which is obligatory; and *directive*, which admit of a certain interpretation.

Another of the service-books of bishops is called the 'Ceremoniale,' but it is chiefly confined to a description of the peculiar ceremonial with which bishops are required to celebrate solemnly those offices, as of the mass, vespers, the funeral office, &c., which are common to them with priests. The most prized editions of both these service-books are those published by authority of the learned pope, Benedict XIV.

PONTINE MARSHES (Lat. *Pomptina Paludes*), a low-lying district, forming the southern part of the Campagna di Roma, and extending in a south-easterly direction from Cisterna to the sea at Terracina. Its greatest length is about 30 miles, and its breadth from 4 to 11 miles. It does not reach the sea-coast on the west, being separated from it by a broad sandy tract covered with forest; but even this barrier partakes to some extent of the character of the marshes themselves, being quite as flat, and largely intermixed with swamp and lagoon. The P. M. have undoubtedly been formed by the stagnation of the streams that take their rise in the Volscian Hills, and by the accumulation of sand along the shore from Astura to the Circeian promontory, but this formation as undoubtedly belongs to pre-historic ages. There is no reason to believe that the P. M. were, in ancient times, essentially different from what they are at present. Pliny, it is true, on the authority of a contemporary, Mucianus, states that at one period they had contained 24 or even 33 cities; but no confirmation of this statement is to be found in any earlier writer, and not a single name of these cities has been preserved. The first attempt to drain the P. M. in ancient times was made in 160 B.C. by the consul, Cornelius Cethegus; but his efforts were only partially successful, for towards the close of the Republic, the region had become as marshy as ever.

Julius Caesar, among his vast schemes for the improvement of the commonwealth, projected one for the drainage of this pestilential district, but his murder prevented its complete realization. Augustus also appears to have done something; but in the time of Juvenal, it was a mere haunt of robbers. Theodoric, the Goth, likewise tried to reclaim it; but the desolations of succeeding reigns soon reduced it to a hopeless condition, and it continued an uninhabitable region until the close of the middle ages. The first in modern times to resume the labors of the ancients was Pope Boniface VIII., who drained the district about Sezzo and Sermonetta by means of a large canal. In 1417, Martin V. made another canal, called the *Rio Martino*, which was dug to within a mile of the sea; but after his death, the project was given up. Several additional efforts were subsequently made; but nothing was really accomplished till the time of Pope Pius VI., who, in 1778, commenced to drain the marshes, and completed the drainage in ten years. The reclamation of the land, however, has been found possible only in part. Though much is under cultivation and in pasturage, a great portion is hopelessly irreclaimable; and the whole region is so unhealthy, that, in the summer months, the inhabitants are obliged to remove to the neighboring mountains.—The famous Applan Way (q. v.) went through the P. M.; and after being unused for centuries, was re-opened by Pius VI.

PONTOO'N (through the French *ponton*, from the Latin *pons*, a bridge), the name given to buoyant vessels used in military operations for supporting a temporary bridge. Pontoon bridges have been constructed with greater or less skill, from the earliest times. Darius passed the Hellespont and Danube by pontoon bridges, and the former was traversed by Xerxes' immense army on similar temporary bridges, very admirably formed. A pontoon train is a necessity for every army manoeuvring in a country where there are rivers, and many campaigns have proved failures from the want of this cumbrous but indispensable apparatus. In most armies, the pontoons are under the charge of the engineers; but in the Austrian army there is a distinct and highly-trained corps, called *Pontonieren*. Marlborough used clumsy wooden pontoons. Napoleon and Wellington had them lighter of tin and copper. They were flat-bottomed, rectangular boats, open at the top. Anchored at stem and stern, beams were laid over from one to another, and transoms with planks crossing these beams completed the roadway of the bridge. These open pontoons were exposed to the disadvantage that they were very liable to be filled with water, and thus ceased to support the bridge. They were, moreover, very heavy, one pontoon, with appurtenances, constituting a wagon-load. As 36 were deemed necessary for the train, a pontoon equipment was a serious item in the

impedimenta of an army. The open pontoons are, now, however, obsolete, modern science having substituted closed cylindrical vessels of copper (or occasionally of India-rubber), which are far lighter, can in an emergency be rolled along, and can only be submerged if perforated. Against the last contingency, they are divided within into water-tight compartments, so that one perforation may not seriously detract from the total buoyancy of a pontoon. In the British service, two pontoons are used: the larger, with hemispherical ends, being 22 feet 8 inches in length, and 2 feet 8 inches in diameter; the smaller, cigar-shaped, with conical ends, 15 feet in length, and 1 foot 8 inches in diameter. Two of the largest used to form a raft weigh 8 cwt. 7 lbs.; the superstructure 18½ cwt.

At 24 feet apart from center to center, this raft, will carry infantry four deep, marching at ease; cavalry, two deep, and light field-guns; at 16 feet interval, heavy guns. A raft of three pontoons, at close distances, will support siege-ordnance. The pontoons can be used in very wide rivers as rafts, in their proper sense, or they can be connected, when the width permits, to form a bridge. In the latter case, each is towed into line, anchored above as it drops to its place, and a second time when its exact spot is reached. It is computed that each pontoon requires 1½ minutes to take its position, and that when the pontoons are placed, the roadway can be laid, if properly arranged previously, in 1½ minutes for each interval between two pontoons. A river of 600 feet may thus be bridged in less than 1½ hours. The process of throwing a bridge over in face of an enemy, is fraught with the utmost danger to the engineers employed. Pontoon bridges have to be passed with great care, and every measure should be adopted, as breaking step, &c., which can reduce the peculiarly dangerous vibration.

PONTUS, the name given by the ancient Greeks to a country in the north-east of Asia Minor, bordering on the Pontus Euxinus (whence its name), and extending from the river Halys in the west to the frontiers of Colchis and Armenia in the east. Its southern limits were the ranges of Anti-Taurus and Paryadres, so that it corresponded pretty nearly to the modern pashaliks of Trebizond and Siwas. On the east and south, P. is mountainous, but along the coast there are large and fertile plains, which in ancient times produced, and indeed still produce abundance of grain, fruits, and timber. Game, according to Strabo, was also plentiful. The rearing of bees was carefully attended to, and honey and wax were among the chief articles of commerce. Iron was the principal mineral.

Regarding the ancient inhabitants of P., nothing is known ethnologically. Greek colonies, indeed, flourished on the coast from the 7th c. B.C., and doubtless spread some knowledge of civilization among the inland barbarians; but how far the latter were influenced thereby, we cannot tell. They first appear as divided into numerous tribes, virtually independent, but owing a nominal allegiance to the Persian kings, whose authority was represented by a hereditary satrap belonging to the royal family of Persia. It was one of these satraps, Ariobarzanes, who, by subjugating some of the Pontian tribes, in the year 363 B.C., during the reign of Artaxerxes II., laid the foundation of an independent sovereignty. Ariobarzanes was succeeded in 337 B.C. by Mithridates II., who took advantage of the civil confusions that followed the death of Alexander the Great, to enlarge his dominions; but the greatest of these Pontine sultans, and one of the most formidable enemies that Rome ever encountered in the east, was Mithridates VI. (q. v.). On the overthrow of this potentate by Pompey (65 B.C.), the western part of P. was annexed to Bithynia, and the rest parcelled out among the neighboring princes. Subsequently, a grandson of Mithridates, Polemon, was installed monarch of the central part of P.; but in the reign of Nero, it was voluntarily ceded to the Roman emperor, became a Roman province, and was called *Pontus Polemoniacus*. In the reign of Constantine, it underwent a new division. The principal towns of ancient P. were Amisus, Polemonium, Pharnacia, Cerasus, Trapezus, Apsarus, Cabira, and Neocæsareia.

PONTYPOOL, a small market-town of Monmouthshire, 20 miles west-south-west of Monmouth, and 10 miles north of Newport, with both of which it is connected by railway. Japan wares were long made here, but this branch of manufacture has declined. Articles in polished iron are made, and the iron forges and coal and iron mines which surround the town employ many of the inhabitants. Pop. (1871) 4834.

PONY, the common name of many small active breeds of Horse (q. v.), belonging to different countries, from India and Africa to Iceland; but in the warmer parts of the world, chiefly found in mountainous or sterile regions. They are in general the property of man, and not truly wild, although, in very many cases, they live almost in a wild state, and receive no care or attention except when they are wanted for use. They are in general very hardy, and their strength is great in proportion to their size. They are often vicious, or at least playfully tricky to a much

greater degree than is usual with larger horses. Ponies are very often covered with rough hair, and have large shaggy manes and forelocks. The *Shetland P.* is a very good example of these small races of horse. The *Iceland P.* is scarcely different from it and is hardly enough to endure the winter of Iceland without shelter. The *Galloway*, *Welsh*, *Dartmoor*, *Emoor*, and *New Forest* breeds, are British races of *P.*, larger than the *Shetland*. The progress of enclosure and cultivation in their native regions has so changed the circumstances in which they long subsisted, and in which, perhaps, they originated, that scarcely any of them is now to be seen of pure and unmixed race. *Sardinia* and *Corsica* have small races of *P.*, which have subsisted unchanged from ancient times. In the *Morea*, there is a race of ponies, driven in herds to Attica for sale, exceedingly wild and vicious, but capable of being rendered very serviceable. But it is unnecessary to mention the many races both of Europe and Asia. They differ considerably in size, some, like the *Shetland P.*, suggesting a comparison with a large dog, some much larger. They also differ much in color; a dun or tan color, with a black stripe along the back, is prevalent in many of them. Ponies are seldom employed in agricultural labors; but they are of inestimable value in many wild and mountainous regions, from their hardiness and surefootedness; and are often used as saddle-horses, the largest kinds being even employed as horses for light cavalry.

POODLE (Germ. *Pudel*), a kind of dog, originally German, but extensively diffused throughout Europe during the wars of the French Revolution, and abundantly introduced into Britain by the soldiers who served in Spain and the Netherlands. It is very closely allied, however, to the coarser crisp-haired *Water-dog*, long well known in England, and particularly to water-fowl shooters and the fishermen of the north-eastern coasts. The *Bardet* of the French is a diminutive variety, much in request as a lady's pet. The *P.* is of a stout form, and has a short muzzle standing out abruptly from the face; the ears are of moderate length, and pendulous; the tail rather short; it is everywhere covered with long curled hair, which in many of the little barbets hangs to the very ground. No kind of dog exhibits greater intelligence or greater affection; and as to both, many interesting stories are on record.

POOLE (so called from the inlet or *pool* on which it stands), is the chief seaport of Dorsetshire, and is situated on a wide but shallow inlet in the east coast of the county. It is built of red brick, is intricate and confused in plan, but is pierced by the High Street, a mile in length. Along the shore are capacious quays, well lined with shipping. The town is more noted for its trade than for its architecture. Sail-cloth and cordage are manufactured, and, together with potters' and pipe clay, provisions, and articles of clothing, form the principal articles of export. Ship, and especially yacht building is carried on. The harbor, into which fall the rivers Trent and Frome, is a beautiful estuary, and is a fine feature in the charming scenery of the vicinity. Its depth of water is 13 to 14 feet, and its navigable channels, being unobstructed by rocks or sands, are perfectly safe at all times. *Brownsea Island*, in the middle of the pool, is 6 miles in circumference. On its extreme point stands the castle of the same name. In 1880, 1014 vessels, of 75,987 tons, entered the port. Pop. (1871) 10,079; (1881) 12,803. *P.* returns one member to parliament.

POOLE, MATTHEW, a learned English divine of the Puritan age, was born at York about the year 1624, and educated at Emmanuel College, Cambridge. Very little is known regarding his life. In 1662, he figures as preacher in the church of St. Michael le Querne, in London; but was one of the 2000 ministers whom the Act of Uniformity compelled to leave the Church of England. Subsequently, he retired to Holland, and died at Amsterdam in 1679. His principal work, *Synopsis Criticorum Bibliorum* (5 vols. fol. 1669–1676), is an attempt to bring together in a condensed form the opinion of 150 biblical critics of all times and countries previous to his own. It is a work showing great (professional) learning, and very respectable talent; but later criticism and research have done much to render it obsolete. Other productions of *P.'s* are *Annotations on Scripture*, and *The Nullity of the Roman Faith*.

POONA, or **PUNA**, the capital of a district of British India, of the same name, in the presidency of Bombay, is situated on the small river Moota, near its confluence with the Moola, in a treeless plain about 74 miles south-east of Bombay. Its present population is estimated (1872) at 90,436; but in its palmy days, when it was the capital of the Mahratta power, it contained more than twice that number. A large proportion of the population consists of Brahmans. The city is divided into seven quarters, named after the days of the week, and the principal building is a palatial structure, formerly the residence of the Peishwah. Its climate is salubrious and pleasant, and it is the headquarters of the Bombay army. The cantonment for the infantry and horse-artillery is from one to two miles west of the city. The cantonment for the cavalry is at the village of Kirkee, about two miles

to the north-east of the city. In 1821, soon after *P.* came into the possession of the British, a college was established for the study of Sanscrit literature, in the hope that the disaffected Brahmans (who had been all-powerful under the Peishwah) might be thus conciliated.

As the modes of instruction originally adopted were entirely native, and far from efficient, the college has gradually been transformed. At present, it possesses a staff of European professors with native assistants, and is a highly respectable seminary for the study of English, Marathi, and Sanscrit. Only Brahmans were admissible into the college as first established; now it is open to the public generally. *P.* is very much resorted to, particularly in the rainy season (from June till October) on account of its pleasant and salubrious climate. The fall of rain averages from 22 to 25 inches annually; whereas at Bombay it is about four times as great. The range of the Ghauts (properly called the Sahyadree range) which rises up as a precipitous barrier 2000 feet high, with peaks considerably higher, receives the full burst of the monsoon; so that Khandalla on the top of the Ghauts is drenched with almost perpetual rain for four months. Then the clouds pass on, relieved of their watery burden, and the rainfall eastward of the Ghauts is much less. From the Ghauts, the whole country gradually slopes towards the Bay of Bengal. *P.* is about 1800 feet above the sea-level. One of the most interesting objects in the neighborhood of *P.* is a large *bund*, or embankment, solidly built of hewn stone over the Mootamoola river for the purpose of providing a supply of water for the cantonment, and especially the bazaar or native town connected with it. It was built by the late Sir Jamsetjee Jeejeebhoy, whose charities were very great. Two forts celebrated in Maratha history are close to Poona—Singhur, about 12 miles to the south-east, and Poorundur, about 18 miles to the south. These are favorite sanatoria during the hot season (from the end of February to June). At Poorundur there is a sanatorium of considerable size for sick soldiers. *P.* was formerly a great mart for jewelry and precious stones, but the trade in these things has quite ceased. The native manufactures have also been supplanted by the introduction of European piece-goods, and the only business that prospers is that of dealers in grain and other agricultural produce. The railway has rendered *P.* almost a suburb of Bombay. The works by which the railway climbs up the great mountain-barrier of the Ghauts from the low lands of the Konkan to the high table-lands of the Deccan are among the boldest that have as yet been undertaken. The line up the Ghauts was opened in April 1863.

Of late years, great alterations have taken place around Poona. The native city has not greatly altered, except that the streets have been widened and cleaned; but the cantonment has changed rapidly. The great fire of 1879 has left its mark on *P.* Among the most striking of the many new buildings recently reared is the Government College—a Gothic building, recently finished, which was erected mainly at the expense of Sir Jamsetjee Jeejeebhoy. While speaking of education in Poona, it is but fair to the Scottish mission to say that it commenced English education in *P.* soon after the mission was established (in 1831), and has all along carried it on. The schools of the mission, both male and female, both for English and the vernacular (Marathi), are largely attended, even by the highest castes. The female pupils are upwards of 300 in number; and one school consists of Musulman girls. The Musulmans in India generally are far behind both Hindoos and Parsees in their desire to educate the females; in fact, a Musulman female school is as yet exceedingly rare.

POONA-WOOD is the timber of the poon trees of India (*Calophyllum inophyllum* and *C. augustifolium*). It is very commonly used in the East Indies, particularly in ship-building, for planks and spars; these latter are usually called *Poon*, and are in general use for masts in that country. The trees are natives of Penang, and of the countries eastward of the Bay of Bengal.

POOP, in large vessels, is a sort of supplemental deck raised over the after-part of the upper deck. The best cabins are situated beneath it. In old ships, a second and even a third poop were raised above the hinder part of the poop proper, giving the vessels that immense height at the stern which is shown in old drawings. The poop is gradually disappearing from ships built either for speed or war, as offering undue resistance to the wind in one case, and an undesirable mark to an enemy in the other.

POOR AND POOR-LAWS. Charity, like Christianity, had its origin, or earliest development, in the East. Among the primitive nations of the world, almsgiving was inculcated as a religious observance, and is prescribed as such in their sacred records. Among the European nations of antiquity, we find a provision for the poor adopted as a matter of state policy. In earlier times, Athens could boast of having no citizens in want; nor did any disgrace the nation by begging. But war, at length, brought poverty in its train, and the Athenian people decreed the maintenance of those who were mutilated in battle; and, at a later period, of the children of those who fell. Plutarch mentions

Peisistratos as the originator of the first decree, though others derive it from Solon. By the latter decree, the state provided for the orphans of its soldiers up to their eighteenth year, and then sent them into the world with a new suit of armor. The bounty given to the disabled is mentioned by Lysias, Harpocratian, Aristotle, Isocrates, and others; and is variously stated at one, two, and three oboli a day, and it seems to have been increased with the increased cost of subsistence. There were also societies for the relief of distress among the democratic states of Greece, called *Eranos*—a sort of friendly society, in which the members relieved were expected to pay back the money advanced to them, when they had raised themselves to better circumstances. But it must be remembered that these so-called democratic states were in reality slave-holding aristocracies.

Among the Romans, the Agrarian and Licinian laws (years of Rome 268 and 338) were framed in order to prevent the extremes of riches and poverty in the state. They limited the extent of property in public land to be held by each citizen, and the latter directed that all such land, above the allotted portion, should be taken away from the holders, and given to those who had none. The distribution of grain at reduced prices, which at length became gratuitous, was introduced by Caius Gracchus, and lasted till the fall of the Roman empire. Augustus in vain tried to suppress it. In his time, 200,000 citizens were thus fed. Cicero makes mention of this provision as in great favor with the Roman people, because it furnished them with an abundant subsistence without labor; other Roman writers describe its results as disastrous both to agriculture and manners, creating a nation of mendicants, and causing the land to fall out of cultivation.

In the middle ages, the great body of the laboring classes were in a state of bondage and looked to their feudal lords for maintenance. The obligation to provide for their slaves, or serfs, seems to have been fully recognized, so that many encountering, in a state of freedom, the miseries of want, went back to bondage as a refuge from destitution. The villeins in Saxon England were attached to the soil, and received from their lord a portion of land for the support of themselves and their families. But the church of Rome constituted herself the great receiver and dispenser of alms. The rich monasteries and abbeys distributed doles to the poor.

In most states of continental Europe, the church remains to a larger or smaller extent the public almoner, the state only stepping in to supplement the offerings of the church and voluntary charity, when they become deficient. The disservice from the church is hardly anywhere so complete as in England. The laws of different countries vary as to the degree of want entitling a pauper to relief, the extent to which the right to relief is a matter of positive right, the conditions which give rise to a claim of relief, and the incidence of taxation. In the Netherlands, a title to relief is acquired by birth, or by having inhabited the same place uninterruptedly for six years. In Sweden, such title as the law allows is conferred by inhabitancy in the parish or town, if the applicant, being above 45 years of age, has been entered on the list of tax-payers. In Norway, the right is acquired by a residence of two years; in Denmark, of five years. By the Prussian poor-law of 1842, the duty of relief falls on the commune of which the person applying was expressly admitted a member, in which he has acquired a regular abode, which he has occupied for a year, or in which he has been living for three years after attaining full age. In Slesvig-Holstein, the right to relief in a commune is acquired by birth; also by 15 years' residence after the age of 18: the latter mode of acquiring it being competent to foreigners. In Saxony, a settlement is acquired by birth, express gift, or purchase of a house and 5 years' residence.

In Spain, the state supports several asylums for lunatics, the blind, and deaf and dumb. It also distributes a large sum annually among the provinces for the relief of the poor—each province being bound to raise double the amount received from the state. The state also steps in for the relief of great calamities, and devotes a certain sum annually for the assistance of unfortunate Spaniards abroad. A general directory of the charitable and sanitary services superintends the parochial bodies charged with the distribution of assistance to the poor.

In Austria, each commune is charged with the relief of its poor. All who have legal domicile, or being unable to prove their domicile, are resident in the commune, are entitled to relief out of the general assessment. There is no special rate, and the administration is strictly municipal. In many provinces, private charity is associated with public assistance, administered by the *curé*, a few chosen inhabitants, who are called 'Fathers of the Poor,' and an officer accountable to the commune. This system is called the 'Poor's Institutes;' and their funds are principally derived from private sources; but they receive a third part of the property of ecclesiastics who die intestate, and certain fines, &c. Applicants are subjected to minute inquiry as to the cause of poverty, and a weekly allowance is made on a scale according to age and necessity. The infirm poor, who have no relatives to reside with, are

taken into hospitals established in almost every commune, where they receive, besides lodging, fire and light, clothing, medical care, and a small allowance in money to provide for their food and other wants. Children are either provided for in the homes of their parents, put into asylums, or boarded with people of probity, who receive a monthly payment, as in Scotland. The welfare of these children is superintended by the *curés*, the *maires*, and the sanitary officers of the commune. Foundlings, lunatics, the blind, deaf, and dumb, are provided for by the state. Vagrancy is punished, and parents permitting children under fourteen to beg are liable to three months' imprisonment. Able-bodied vagrants are sent to houses of correction, and kept to work. Pawnbroking is a charitable institution in Austria, under government control; and many pawnbroking establishments rest on endowments, and lend without interest. The trade is forbidden to private persons.

In France, the relief of the poor is not compulsory, in as far as its distributors may, after making inquiry, refuse relief, except in the case of foundlings and lunatics. The Minister of the Interior has a general superintendence of the machinery of relief, as well as the immediate administration of many large hospitals and refuges. He also assists a great number of private charities. The other ministers of state give assistance on the occurrence of great calamities. The departmental funds are called upon for the compulsory relief, but the commune is the main source of public assistance. Its duty is to see that no real suffering remains unrelieved, and that the nature of the relief is such as can most easily be discontinued when the necessity ceases. The commune encourages and stimulates voluntary charities, and receives gifts for the benefit of the poor's funds. Except in Paris, the administration of the hospitals, and of the relief given at the homes of the poor, are under different management, the communes only interfering to supplement the funds of the hospitals, when these are insufficient. The *maire* is president both of the administration and the hospitals and of the body for giving out-door relief (the *bureau de bienfaisance*). During industrial calamities, the poor are sometimes employed in workshops supported by the public, and in public works. In Paris, since 1849, there has been a responsible director set over all the charities of the city. He manages the out-door relief through the medium of the Committees of Assistance, formerly called *bureaux de bienfaisance*, in each *arrondissement*. He is under the inspection of a council, composed as follows: The Prefect of the Seine (president), the Prefect of Police, two members of the Municipal Council, two *maires* or deputy-*maires*, two members of the Committees of Assistance, one councillor of state or a Master of Requests, one physician and one surgeon practising at the hospitals, one professor of medicine, one member of the Chamber of Commerce, one member of the Council of Prud'hommes, and five members taken from other classes than those above mentioned. Begging is forbidden, and punished, wherever there are establishments for the relief of the poor.

In the Hanse Towns, there was introduced, in 1788, a system of voluntary contributions aided by fixed subsidies from the government. This at length resulted in government supplying all deficiencies, which in the last few years have been 80 per cent. of the cost of the general poor relief. In Holland, pauper colonies have been supported by government for the last forty years. Vagrants, after a short imprisonment, are sent to one of these, under a system of discipline quite as rigorous as an Irish intermediate prison. Paupers of good character are sent to maintain themselves and their families, by agricultural labor, in free colonies. The working of the system is pronounced costly and unsatisfactory.

In America, the system is very similar to our own. Every man is entitled by law to relief from the town of his settlement, the rate being assessed on whole towns, and not on parishes. The States have their own poor-laws, but paupers are removable from one state to another. Any American becoming a pauper loses his state rights. The acts concerning Workhouses and Paupers in the Revised Code of Massachusetts may be taken to represent generally the state of the law throughout the Union. The former provides 'that any town may erect or provide a workhouse for the employment and support of all poor and indigent persons that are maintained by, or receive alms from the town; all persons who being able to work, and not having means to maintain themselves, refuse or neglect to work; all persons who live a dissolute vagrant life, and exercise no ordinary calling or lawful business; and all such persons as spend their time and property in public-houses, to the neglect of their proper business, or by otherwise mis-spending what they earn, to the impoverishment of themselves and their families, are likely to become chargeable to the town or the commonwealth.' The idle and the vagrant may be committed to the workhouse, and kept to labor as in a house of correction. There are no provisions for enforcing the claims of kindred, and for the immediate relief of strangers. The administration is in the hands of overseers, who have discretion as to the mode of relief.

The annals of the poor in England are neither short nor simple. Severe enactments for the repression of vagabondage and mendicancy date from an early period. In ancient Saxon times the householder was bound to provide for the laborer, and men who had no master were, by the Rolknote, assigned to some householder; but when freedom began to prevail, this state of things ceased. No master was bound to provide for the freeman, and when he failed to provide for himself by honest labor, he generally took to vagrant begging, often to violence. The statute of Winchester (13th Ed. I., 1285) shows the poor utterly uncared for, and the roads infested by vagrant robbers. Up to the reign of Richard II., the idea of English rulers was to treat pauperism as a crime, and repress it by punishment, and by the most unjust and absurd restrictions on the freedom of labor. The 23d Ed. III. forbids giving alms to vagrants, on pain of imprisonment; then also the laws of settlement had their origin in the attempt to chain the free laborer to the land. See SETTLEMENT. The 12th Richard II. (1388), c. 7, is the first statute that makes provision for the impotent poor. The statutes of Henry VII. endeavor to carry out, by the severest measures, the system of repression. The 27th Henry VIII. c. 25 (1535), introduced the principle of compulsory assistance. Each parish was ordered to receive and provide for the impotent, and set the able-bodied to work. Alms were to be collected into a general fund, and indiscriminate almsgiving was forbidden. The sturdy beggar was treated without mercy, was to be whipped when first caught, next to have his ear cropped, and for a third offence, to suffer death, as a felon and enemy to the commonwealth. This is repealed by 1st Ed. VI., c. 3 (1547), because, 'through foolish pity, it is rendered of non-effect.' Not much milder, to modern ideas, seem the substituted penalties—viz., branding, on first conviction, with a V on the shoulder, and being adjudged a slave for two years, to be claimed by any one, fed on bread and water, and caused to work by beating, &c.

Running away from this tender treatment was punishable with S branded on the face, and slavery for life to the town or parish, on the roads of which the incorrigible vagrant was to work in chains, at the penalty of the town or parish. Other two acts of Edward's reign return to earlier and considerably milder measures of restraint. A little urging was now found necessary to obtain funds for the maintenance of the poor. The collectors were gently to ask every man and woman at church what they would give; but if one could not be persuaded, the bishop was to send for the recusant, and use 'charitable ways and means.' At length, the 5th Elizabeth, c. 3 (1563), provided that he who obstinately refused to give should be handed over to the more persuasive arguments of the justices, who were empowered to tax him at their discretion, and send him to jail for default. Ten years later, the power of compulsory assessment is given to the justices, and abiding places are ordered to be provided for the aged and infirm. These statutes culminated in the 43d Elizabeth, c. 2 (1601), which has formed the basis of the poor-law system of England up to the present time. It taxed every inhabitant of every parish for the relief of the poor. It directed the justices in every county to appoint three or four substantial householders in each parish to be overseers of the poor, along with the churchwardens. It ordered the relief of the impotent, and the apprenticing of children, and the providing of work for the able, by means of 'a convenient stock of flax, hemp, wool, thread, iron, and other necessary ware and stuff.' The great act of Elizabeth came but slowly into operation. Up to the reign of Charles I., there were many parishes in which no rate was assessed, and which turned away their poor; but the great evils had been remedied, and there is little legislation on the subject for the next hundred years.

The 3d William and Mary, c. 2. (1691), an act relating chiefly to settlement, provides that the persons to be relieved be registered and examined by the vestry, because evils had arisen out of the unlimited power of the churchwardens and overseers giving relief for their own private ends, 'by which the charge on the parish was greatly increased, contrary to the true intent of the statute of Elizabeth. This act also gave power to the justices to order relief in cases of emergency, a provision which afterwards became a fruitful source of difficulty. The evils henceforth complained of were, that many had thrown themselves on the rates who ought to have been supporting themselves independently of such aid; that pauper labor was found interfering with and displacing industrial labor; that the overseers were acting with unchecked dishonesty; and justices, with unrestrained liberality, ordering the money of the industrious and prudent to be spent upon the idle and improvident. Efforts were made to remedy these abuses throughout the reigns of the first three Georges, by making the justices act with the overseers, by rendering the overseers accountable to the parishioners by means of returns and the power of inspection, and by the offer of the workhouse to all applicants for relief. This last provision, made in the reign of George I. (9th Geo. I., c. 7, 1723), substituted what is called in-door relief, for the allowance made to the poor at their own homes, and introduced the workhouse system. All who refused to be lodged

in the house, were to be struck off the poor's-roll, and refused relief. A great increase in the number of workhouses took place; guardians were appointed to guard the pauper children from neglect and improper conduct, and other attempts to improve their administration made; Work-house Unions were also introduced by an act called Gilbert's Act (1782), and a succession of acts passed for the protection of parish apprentices.

Towards the close of the 18th c. a great relaxation took place in the treatment of the poor. The 38th Geo. III., c. 10 and 23 (1796), increased the amount, and extended the application of relief. It repealed the act forbidding relief to those who refused the workhouse, and allowed relief to be given in aid of wages. Henceforth, out-door relief became the rule under a variety of systems, of which the complaint was justly made, that they turned the poor-laws into a mode of paying wages. In 1801, the amount of the rates was reckoned at £4,000,000. In 1820, it had risen to £7,380,254. In 1817, a commission of the House of Commons stated their opinion, that unless checked, the assessment would swallow up the profits of the land. Though the two Vestry Acts, which resulted from the commission appointed in 1817, seem to have done something to remedy the evils complained of, a new commission to inquire into the operation of the poor-laws was found necessary, and appointed in February 1832. The evidence brought before this commission revealed a disastrous state of things. The independence, integrity, industry, and domestic virtue of the lower classes were in some places nearly extinct. The great source of the evil was shown to be the relief afforded to the able-bodied on their own account, and that of their families, in aid of wages. This aid at first reduced the expenditure in wages, and found favor with farmers and magistrates, who framed scales of relief in accordance with the wants of the people, so that they began to be paid for their necessities, and not for their industry, and fell into the temptation of increasing the former, and neglecting the latter. Five modes of out-door relief were found in operation: 1. Relief without labor; 2. Allowance given, in aid of wages, according to the number of the laborer's family; 3. The Roundsmen system, the laborers being let out, by the parish, among the employers round; 4. Parish work, generally on the roads; 5. The labor-rate, the ratepayers preferring to divide among them the pauper labor, and to pay for it, however valueless, instead of raising a rate. Diminished industry ate away the very root of capital. Farmers turned off their men, or refused to employ them at fair wages, thereby causing a surplus of unemployed labor fraudulently, they then took them back from the parish at reduced wages, paid out of the rates.

Under the system of allowance, there were parishes in which every laborer was a pauper, paid more for idleness than he could get for labor, paid more if he took a pauper wife, and still more for every pauper child. Paupers married at 17 and 18 years of age, and claimed the allowance the day after their marriage; and from parish after parish came the reply to the queries of the commissioners: 'All our able-bodied laborers receive allowance.' No poor man in such parishes could save; if industrious and thrifty, and it was known that he had a fund of savings, 'he would be refused work till the savings were gone,' and he had come down to the pauper level. This had gone on, till in many places pauperism swallowed up three-fourths of the rent. Nor was the maladministration confined to the rural districts; the evidence showed that it extended all over the country, and into the manufacturing towns, where the out-door relief was a source of constant imposture. The administration of in-door relief was also full of abuses, from want of classification, discipline, and employment. Better food and lodging was provided for idle paupers than working-people could procure—better, even, than could be afforded by many of the ratepayers. In 1834, the commissioners reported that they found the administration 'opposed to the letter and spirit of the law, and destructive of the welfare of the community.' The commissioners strongly laid down the principle, that the condition of the pauper ought to be below the lowest condition of the independent laborer, because every penny bestowed in rendering the condition of the former more eligible than that of the latter, is a bounty on indolence and vice, and recommended: 1. The cessation of out-door relief; 2. A central authority to control the administration; 3. Unions for the better management of workhouses, and the classification of their inmates; and 4. A complete and clear system of accounts. The bill embodying these recommendations was brought in, March 17, 1834, passed its second reading in the House of Commons with only twenty dissenting votes, and became law on the 14th August as the 4th and 5th Will. IV. c. 76. This act was not a change of law, but of administration.

The orders of the new board restricted overseers, on the formation of a union, to the collection of rates; appointed paid relieving-officers to dispense relief under the directions of the unpaid Boards of Guardians; required the gradual withdrawal of out-door relief; and enforced classification and discipline in the workhouses. A rapid formation of unions took place under the

new board. In the first eight months, 112 were formed out of 2066 parishes. The pauperized districts experienced a great and immediate relief, numbers of paupers going off when they found that relief involved adequate work, or the strictly-disciplined workhouse; wages rose, and the expenditure was reduced, on an average, 20 per cent. At the accession of George I. in 1714, the poor-rates amounted, as nearly as can be estimated, to £950,000, equal to 3s. 3½d. per head on the population of 5,750,000. At the accession of George III, in 1760, the population had increased to 7,000,000, the poor-rates to £1,250,000—an average of 3s. 6½d.; while in 1894, the population, estimated from the last census, was 14,372,000, and the money expended in relief, £6,317,255—equal to 8s. 9½d. per head. In three years, the operation of the Amendment Act had reduced the expenditure one-third, viz., to £4,044,741. In 1848, the commissioners were exchanged for a public board, which is one of the government departments, with a president, in whom has been vested the power of the commissioners, and who holds office as one of the ministers of the crown. There are 631 unions. In 1860—1861, the number of poor receiving relief in England was about 850,000, about 4½ per cent. on the population; of these, about 140,000 were relieved in workhouses. The commissioners were unable to withdraw out-door relief, which continues to be in England the most important item. With the aged, the sick, and orphans, the guardians deal at their discretion; but stringent rules for the relief of the able-bodied are in operation under the board, whose orders have the force of laws.

In the rural districts, guardians are prohibited from giving relief to the able-bodied out of the house, unless under a supplemental order, in emergency. For other places, the general rule forbids relief to be given in aid of wages, and requires work to be supplied. Exceptions are made by the board on the application of the unions when necessity arises, as in the recent case of the cotton districts. The expenditure is strictly guarded and examined by public auditors, of whom there are fifty-four for England. A district medical officer, of whom one or more are appointed for each union, attends to all cases of sickness among the poor.

Scotland and Ireland have been legislated for separately. Their poor-laws are similar to the English in principle and practice; both are administered by a Central Board, which supervises the local bodies charged with relief, and in both the rate is levied on the annual value of real property. The present system in Scotland was instituted by the 8th and 9th Vict. c. 83 (1845). Scotland is divided into 883 parishes, some of them combined for poorhouse accommodation. The relief is administered by a parochial board, appointed by the ratepayers, the burgh magistrates, and the kirk-session. They appoint inspectors of the poor, who act as relieving-officers. The Scotch law differs from the English and Irish in allowing no relief to able-bodied adults. Claimants must be aged, infirm, or disabled. Out-door relief is the rule. As regards the working of the Scottish poor-law, its great and acknowledged defect is the constant and costly contest respecting settlements, or right to fix claims on particular parishes. Scotland had, in 1874, 64 poorhouses for 406 parishes, having a population of 2,407,441. Ireland had no poor-laws until the year 1838, when they were introduced by the 1st and 2d Vict. c. 56. For the purpose of relief, Ireland is divided into 163 unions of townlands or parishes. Each union has a workhouse managed by a Board of Guardians, elected by the ratepayers. Every destitute person has an absolute right to relief, which is administered almost entirely in the workhouse.

The average yearly population of the United Kingdom during the ten years ending 1870, was 29,694,188; average paupers in each year, 1,140,185, or 3·9 per cent. They were apportioned as follows:

	Population.	Paupers.	Percentage.
England.....	20,998,332	973,860	4·6
Scotland.....	3,044,919	100,927	3·3
Ireland.....	5,650,897	65,398	1·2

The total expenditure in the United Kingdom during the ten years was £80,901,456, or an annual charge of 5s. 5½d. per head on the average population of the period, apportioned as under:

	Amount of Assessment.	Per head per annum.
	£	s. d.
England and Wales.....	67,286,674	6 4½
Scotland.....	6,191,066	4 0½
Ireland.....	7,423,716	2 7½

To look back ten years, the rate which, at the end of the financial year 1861, was 5s. 9d. a head on the population, was 6s. 4½d. two years after—a fact due to the cotton famine. Applying similar calculations to the five years 1871—1875 gives the following results: estimated annual average population of the United Kingdom, 32,129,865; annual average of paupers, 1,109,608, or 3·4 per cent, distributed thus:

	Population.	Paupers.	Percentage.
England and Wales..	23,355,535	920,030	3·9
Scotland.....	3,430,930	112,132	3·25
Ireland.....	5,343,400	77,446	1·4

The total expenditure for the same period was £47,532,756, or an annual average charge of 5s. 0½d. per head of population—in England and Wales, 6s. 7½d.; Scotland, 5s. 1½d.; Ireland, 3s. 6d. At the beginning of 1880, there were 837,940 paupers in England and Wales; at the beginning of 1881, 803,126. In Scotland there were 34,413 paupers in 1881; and in Ireland, 549,874.

There is no poor-law in our Australian colonies, but benevolent asylums for the infirm and destitute have become general, and hospitals are numerous in all the rising towns in the gold-fields.—Compare Böckh's *Public Economy of Athens*, translated by Sir G. C. Lewis; Sir George Nichol's *History of the Poor-laws*; Emmingham's *Poor Relief in different parts of Europe*, revised by E. B. Eastwick (1873); *Report of the Poor-law Commissioners* (1835); *Reports of the Poor-law Commission and Poor-law Board from 1835 to 1875*.

POOR, GENERAL LAWS AS TO. The fundamental rule as to the relief of the poor was, that each parish in England and Wales is bound to maintain its own poor. For the purpose of providing the requisite machinery, overseers are required to be appointed in each parish every year on the 25th March, or within a fortnight following; and these, along with the churchwardens, who are *ex officio* overseers, have the duty of providing the requisite funds. See **OVERSEERS**. This is done by means of a poor-rate, which the churchwardens and overseers may levy on all the occupiers of land in the parish, after such rate has been confirmed by the justices. The rate specifies a certain sum in the pound which is to be levied, and the annual value of the various lands is then specified, and the amount is thus easily computed. The rate is thus a local tax on the occupier of the land, and not on the owner, unless he himself is also occupier. In all cases, the duty of raising the funds attaches to the overseers; but the actual distribution and application of them are not always in their immediate control. Owing to the mischiefs arising from the officials of each parish distributing the funds at their discretion, without uniformity of plan, a central controlling power was created in 1834, in the shape of the Poor-law Board; and authority was given to combine various parishes into one poor-law union, for the purpose of greater uniformity as well as economy. When a union is formed, the control of the expenditure is chiefly vested in the guardians of this union, who are elected by each parish, and who supervise the management of the union workhouse. They order the overseers of each parish to raise their due proportion of funds, by a contribution order issued to such overseers, who are thereon bound to levy the amount by including it in the next poor-rate. The guardians are bound to contract for the provisions, clothing, fuel, &c., supplied to the workhouse, by means of sealed tenders, unless the quantity is less than a stated amount. All the controlling powers formerly vested in the Poor-law Board are now transferred to the Local Government Board.

The principle on which relief is administered to the poor is, that the condition of the pauper should not be so comfortable as that of the lowest independent laborer; otherwise, idleness and imposture would be encouraged to an indefinite extent. The guardians profess only to relieve destitution already existing, and not to enable persons to keep off impending destitution. Hence they only supply the bare necessities of life. They cannot, for example, advance or lend money to set up a poor person in trade. Minute regulations are contained in the consolidated poor-law orders of the Board as to the classification of paupers in the workhouse, mode of admission, diet, discipline, and out-door relief. With regard to out-door relief and able-bodied paupers, it is provided, that every able-bodied person requiring relief from any parish, shall be relieved wholly in the workhouse, together with his wife and family, if any, and if not otherwise employed. But the relief may be given out of doors in cases of sudden and urgent necessity, of sickness, accident and a few other cases. In general, relief is confined to persons actually residing in some place within the union, except in case of casual destitution, or sickness and accident. Whenever out-door relief is given to an able-bodied person, half of it is to be in the form of articles of food or fuel. Relief is given only weekly, where the pauper is not required to be received into the workhouse. No relief is to be given to able-bodied persons while they are employed for wages or hire by any person; and every able-bodied male person, if relieved out of the workhouse, shall be set to work by the guardians, and kept so employed while he continues to receive such relief. The law with regard to the relief of the poor is so far qualified, that wherever a person applies for parochial relief, if he or she has a father or grandfather, mother or grandmother, or child, who is able to maintain such pauper, then the parish officers can obtain an order from justices to compel such relative to contribute a sum towards such maintenance. So husbands or

fathers of paupers are bound to contribute to such maintenance. In all cases, the pauper is relieved either in the workhouse or out of the workhouse, according to the regulations of the poor-law orders.

In some cases, the guardians or overseers may employ the poor in public works; but this is seldom done, except on occasions like the Lancashire distress. The law as to the settlement of the poor is somewhat intricate, and gives rise to much litigation. There are various grounds on which this settlement is acquired. Thus every person has, *primâ facie*, a settlement in the parish where he was born, until, some other is proved; and there are so many other qualifications, that it is seldom a birth-settlement is resorted to. By marriage, a woman immediately acquires the settlement of her husband, if he has one, whether the husband be an Englishman or a foreigner. If the husband has no settlement, then the wife is thrown back on her maiden settlement. Formerly, a person acquired a settlement in a parish by hiring and service, and by residence for forty days under such hiring; but since 1834, no such settlement can be acquired. If any person shall be bound an apprentice by indenture, and reside forty days under such apprenticeship, he or she acquires a settlement thereby. So whoever shall rent a tenement in a parish, and actually occupy the same, and be rated to the poor for one whole year, the rent being not less than £10, and paid by the person so actually occupying the tenement, shall acquire a settlement. So a person acquires a settlement by acquiring an estate in land, however, small in value, and residing forty days in the parish. So, if a person buy an estate, and the consideration amount to £30 at least, he shall thereby acquire a settlement. Formerly, a settlement was acquired by serving a public annual office, such as that of constable, overseer, &c.; but no settlement is now acquired on that ground. Unless a pauper has acquired a settlement on one or other of the grounds before mentioned in the parish or union where he receives relief, he is liable to be removed compulsorily to the parish where he last acquired a settlement. Certain persons, however, cannot be removed, and these are called irremovable paupers. Such are those paupers who have resided for one whole year in the parish or union in which they became destitute.

The mode of computing this one year is, however, somewhat difficult in certain cases. The expense of maintaining the poor generally is paid out of the common fund, and not by each parish in the union. When a pauper is sought to be removed, it is necessary to take him before two justices of the peace for examination; and on proper evidence of his settlement, the justices will make the order of removal, which is an authority to the overseers to take or send the pauper to the overseers of the parish of settlement. If, however, the pauper is too ill at the time to admit of removal without danger, the justices may suspend the order of removal till he is recovered. Whenever a pauper is to be removed the removing union is bound to give notice to the union of settlement; and it is on these occasions that so many obstinate and costly litigations take place as to which is the union of settlement. Much litigation was avoided by substituting a union for a parish as the test. The union also may appeal to the Court of Quarter-sessions against the removal order; and the Quarter-sessions may state a case for the opinion of the Court of Queen's Bench, if any nice point of law should arise, as frequently happens.

In Scotland, there was no systematic provision for the relief of the poor until 1845, when the statute of 8th and 9th Vict. c. 83 was passed. By this statute, a central board (called the Board of Supervision) was established, which controls the parochial board of each parish or union of parishes in a manner similar to the Poor-law Board in England. A settlement can be acquired in Scotland by residence of five years. Children follow the settlement of their parents, and wives that of their husbands; and if no other settlement be proved, then the settlement of birth is liable. In Scotland, the mode of assessment differs from that in England, where only the annual value of lands and tenements can be rated in the hands of the occupier.

The parochial board had the option of three modes of assessment: 1. One half to be paid by owners, and one half by the occupiers; 2. One half to be paid by owners of lands, and the other half to be paid by all the inhabitants, according to means and substance other than lands; 3. Assessing owners of lands and other inhabitants rateably according to their means and substance. But by a later act of 24th and 25th Vict. 37, the mode of assessing means and substance is abolished. It will thus be seen that in Scotland the poor-rate can never be imposed wholly on the occupier as it always is in England.

In Ireland, a Poor-law Act was also, in 1838, passed, and numerous amending statutes have followed, the code of laws being substantially founded on the English acts.

There are special acts of parliament regulating the conditions on which paupers are removable between England, Scotland, and Ireland respectively.

POOR-RATE. See **POOR**; **OVERSEERS**.

POOR'S-ROLL, in the practice of the law of Scotland, means the list of poor persons who are litigants, but unable to pay the fees of court, and therefore are allowed to sue *in formâ pauperis*. As this is considered a privilege, and enables the person to secure the services of counsel and agents gratuitously, it is only granted on production of a certificate by the minister of the parish and two elders, setting forth his circumstances to their own knowledge and his general poverty. Notice is given of this to the adverse party, who is allowed time to inquire and oppose the application. When the court is satisfied of the poverty, the next thing is for the court to remit the matter to the counsel for the poor, of whom there are always two annually appointed by the Faculty of Advocates, generally young counsel, for the purpose: one of these counsel reports whether there is a *probabilis causa*, i. e., a good cause of action. If this report is made, it is considered conclusive, and the party is put on the poor's-roll. This warrant remains in force for two years, and during that time, the pauper is exempt from all fees of court, and has the gratuitous services of counsel and agents. This provision for enabling paupers to carry on litigation, which is so complete in Scotland, is unknown in England or Ireland; for though a party may also be allowed there to sue *in formâ pauperis*, no provision is made by the court for giving him the gratuitous services of counsel and attorney; nevertheless, these sometimes volunteer to act gratuitously. See **IN FORMA PAUPERIS**.

POPAYAN, a city of the United States of Colombia (New Granada), South America, stands in a fertile plain, 6000 feet above sea-level, on the Cauca, in lat. 2° 27' N. It contains a cathedral and a number of conventual edifices. It was founded in 1537, and was the first city built by Europeans in this region. Under the Spaniards, it rose to considerable importance; but an earthquake in 1834, and the continued unsettled state of the country, have done much to reduce it. It is still of some consequence as a mart for agricultural produce. A great commercial road, about 1000 miles in length, leads from P. to Truxillo, in Peru. Pop. 20,000.

POPE (Gr. *papas*; Lat. *papa*, father), the title of the Bishop of Rome, and Supreme Pontiff of the Roman Catholic Church; applied also to all priests of the Greek and Russo-Greek Church. Under very many heads, occasions have arisen requiring reference more or less detailed to the authority and the privileges ascribed to the Bishop of Rome by the church of which he is the head. We propose in the present article to explain briefly the titles of the pope, the manner of his election, the nature and functions of his office, and the authority ascribed to him by the different schools of Catholics; and finally the chronological succession of the bishops of Rome from the earliest ages to our own day.

1. The name 'Papa' (q. v.)—the Latin equivalent of pope—was originally used of all bishops. The first known writer who applies it to the Roman bishop as his specific title, is Ennodius of Pavia, in the latter part of the 5th c., who thus addresses Pope Symmachus. It is used also by Cassiodorus; and from his time gradually came to be reserved to this application, but it did not lose entirely its old and general use for many centuries later. In the modern ecclesiastical vocabulary, the pope is called the 'Sovereign Pontiff,' the 'Vicar of Christ,' the 'Head of the Church,' the 'Holy Father,' &c. He subscribes himself, since St. Gregory the Great, *Servus Servorum Dei* (Servant of the Servants of God); and he is addressed as Your Holiness, Your Beatitude, &c.

2. The office of pope is elective. The electoral body, according to the present usage, is the College of Cardinals. Primitively, the pope, as the other bishops, was elected by the clergy and people, although the rights of both were not the same. Some elections having been attended with violence, the electoral body was by degrees limited. At length, by a decree of Pope Nicholas II. in 1059, the right of election was vested in the cardinals. Provision was thus made for a representation of all the ancient electoral bodies; the cardinal bishops representing the bishops of the Roman synod; the cardinal priests the parish clergy, and the cardinal deacons, the heads of the popular electoral districts (*regiones*) of the city. Preparatory to an election, the cardinals are shut up in what is called 'the conclave,' all communication with the outer world being interrupted until the election shall have been made. A simple majority of voices does not suffice—two-thirds of the cardinals must vote for the same candidate. There are four modes of election—'scrutiny,' 'access,' 'compromise,' and 'inspiration.' Twice a day during the conclave, each cardinal deposits, in a chalice placed on the altar, the name of his candidate. If the requisite number of votes are not found for any one, the papers are at once burned; and the smoke of the burning votes is a signal to the expectant crowd outside that no election has taken place. This is called the 'scrutiny.' If votes be added to those already given for one candidate, so as to make the required two-thirds, it is called 'access.' If the cardinals of two parties unite, it is called 'compromise.' If by a public movement,

a particular candidate be carried as if by acclamation, the election is said to be by 'inspiration.'

Pope Pius IX., was elected in this way. The greater Catholic powers—France, Austria, and Spain—were formerly understood to have the privilege of placing a veto upon the election of one candidate; but this right was vague and undefined, and had no formal foundation in law. It is required by long usage, as a condition of election, that the candidate shall be an Italian. After election, the pope is enthroned, enters upon possession of his see, and finally, is solemnly crowned. The ceremonial of consecration is very splendid and deeply impressive. One of the ceremonies—that of burning a bunch of flax before him, with the words: 'Holy Father, thus passeth away the glory of the world!'—has often been cited for its highly symbolical character, as well as for its dramatic effect. Cardinals, in order to vote, must be present at the conclave—no voting by proxy is permitted. Some of these conditions are practically set aside by the cessation of the status of the pope as an Italian temporal sovereign; and it is not unlikely that the forms of election may be modified by special legislation. It has even been alleged that Pope Pius IX., prepared a special bull regulating the time, place, and order of the election of his successor.

3. The general nature of the office of the pope may be inferred from his reputed character as successor of St. Peter, and vicegerent of Christ on earth, whence follow all the powers necessary for the practical government of the church. Hence he is held (1) to possess over the entire church, and each of its parts, a supreme authority, not indeed arbitrary, but regulated by the law of God and by the canons. He has power (2) to examine and decide authoritatively all controversies; (3) to convoke councils; (4) to revise and confirm their decrees; (5) to issue general decrees, whether upon discipline and morals, or upon doctrine; (6) he is the center of communion, separation from which involves the forfeiture of the communion of the whole church; (7) he has *ultimate* authority to appoint bishops in all parts of the church, and however this right may be exercised in the first instance, as by the sovereign, by the clergy, or by a synod of bishops, it rests with him to confirm episcopal elections, no matter how made, and to grant 'canonical institution;' (8) he can also deprive bishops, and set others in their place; and can even, in cases of great emergency, suppress bishoprics, and change their limits according to existing requirements; (9) he has authority to judge of the doctrine taught in particular books, or by particular individuals, and to pronounce authoritatively as to its conformity with the Catholic faith, or the contrary. This privilege formed the subject of the great controversy with the Jansenists as to what are called Dogmatic Facts.

4. All Catholics are agreed that the pope, as primate, possesses, by divine law and in virtue of his office, full governing authority over the entire church. Of the exercise of such power, they find traces in history from the earliest times. Roman Catholic historians trace the history of the pope's primacy in St. Clement's Letters to the Church of Corinth, in the action taken by Victor in the Paschal controversy, and by Stephen and Cornelius in the controversy on re-baptizing heretics; in the deposition of Marcian, Bishop of Arles, at the instance of Cyprian, by Pope Stephen; in the leading part taken by the popes in the condemnation of Donatus and of the Pelagian heresy; and perhaps more than all, in the appeals made from various parts of the church by persons excommunicated by their own bishops, and the rehearing at Rome of such causes, and the confirmation or reversal of the sentence according to the result of the trial. These several facts, however, although to Catholics they appear evidences of the papal supremacy, are explained by Protestant writers in a sense which does not suppose any permanent supremacy on the part of the Roman See, and which they hold to be reconcilable with the full independence of national churches; and it is admitted by Catholics themselves, while they contend that the instances to which they appeal imply a real exercise of primacy from the beginning, that the details of that primacy have undergone a gradual and extensive development in the progress of the church. Up to the date of the late Vatican Council, great differences of opinion existed between the Gallican and the Ultramontane schools as to the extent and nature of the papal authority, whether in decrees of doctrine or in the government of the church.

As to the former, all agreed that the judgment of the pope, in concert with the body of bishops, was infallible; but they differed as to papal decrees on doctrine issued by the pope alone, *ex cathedra*, and addressed to the whole church, although both agreed as to the duty of respectful obedience on the part of all, until the general sense of the church should have been ascertained; and should no reclamation on the part of the church take place, the decree of the pope was held to be, in the opinion of both the contending schools, as infallible; and the doctrine propounded therein was allowed to be recognized as a question of faith, which had been sanctioned with the ultimatum of infallibility. See GALLICANISM. But the Ultramontanes held that a doctrinal de-

cree issued *ex cathedra*, is infallible *ipso facto*, and independently of any reference to the church dispersed. As to the government of the church, the Ultramontanes held the pope to be supreme, and thus to be superior to general councils, and independent of their decrees. The Gallicans, on the contrary, held that a general council is superior to the pope, and has power to bind him by its decrees. Further the Ultramontanes held that the pope is the source of all jurisdiction in the church, and that the bishops derive their powers *through him* from Christ. The Gallicans regarded the episcopal power as received directly from Christ by virtue of the episcopal office. This difference of opinion leads to many controversies of details as to the respective rights and powers of the pope and the bishop in the several dioceses, regarding which it is only necessary to indicate the general ground of difference of opinion. With regard to all, it may be said that both on the question of infallibility and on all its practical consequences, the Ultramontane view, although not in its most extreme form, has received the sanction of the late Vatican Council.

5. The chronology of the papacy in the 1st c. is very obscure. The enumerations in the ancient writers are imperfect, and they differ as to the exact order of succession. The two most ancient catalogues, those of Irenæus and Augustine, differ in more than one particular. The chief difficulty regards Linus and Cletus. The former is believed to have been the vicegerent of Peter during the interval between his first coming to Rome and his final residence there. He would therefore have been at once the contemporary of Peter and his successor (though but for a very brief period). The difficulty as to Cletus arises from the doubt whether he be the same person with Anacletus. We subjoin a catalogue drawn up after the most careful modern authorities, and arranged according to centuries:

	FIRST CENTURY.	A. D.
St. Peter.....	41—67	
Linus.....	68	
Cletus, or Anacletus.....	uncertain date	
Clement I.....	uncertain date	
SECOND CENTURY.		
Evaristus.....	about 100	
Alexander I.....	about 109	
Sixtus I., Roman.....	119	
Telesphorus, Greek.....	127	
Hyginus, Athenian.....	138	
Pius I., native of Aquileia.....	142	
Anicetus, Syrian.....	151	
Soter, Greek.....	161	
Eleutherus, Greek.....	170	
Victor I., African.....	185	
Zephyrinus.....	197	
THIRD CENTURY.		
Callixtus I., Roman.....	217	
Urban I., Roman.....	222	
Pontianus, Roman.....	230	
Antherus, Greek.....	235	
Fabianus, probably Roman.....	236	
Cornelius, Roman.....	252	
(Novatianus, first antipope.)		
Lucius I., Roman.....	253	
Stephen I., Roman.....	253	
Sixtus II., Roman.....	257	
Dionysius, Greek.....	259	
Felix I., Roman.....	270	
Eutychianus, uncertain.....	275	
Caius, Roman.....	283	
Marcellinus, Roman.....	296	
FOURTH CENTURY.		
Marcellus I., Roman.....	308	
(Marcellinus having died in 304 or 305.)		
Eusebius, Greek.....	310	
Melchisedes, African.....	310	
Sylvester I., Roman.....	314	
Marcus, Roman.....	336	
Julius I., Roman.....	337	
Liberius, Roman.....	352	
(Felix II., antipope.)		
Damasus I., Spaniard.....	366	
(Ursicinus, antipope.)		
Siricius, Roman.....	384	
Anastasius, Roman.....	398	
FIFTH CENTURY.		
Innocent I., native of Albano.....	401	
Zosimus, Greek.....	417	

		TENTH CENTURY.	
		A.D.	A.D.
Boniface I., Roman.....	418	Benedict IV., Roman.....	900
Celestinus I., Roman.....	422	Leo V., native of Ardea.....	903
Sixtus III., Roman.....	432	(Christopher, antipope.)	
Leo I., Roman, called 'the Great'.....	440	Sergius III.....	904
Hilarius, native of Sardinia.....	461	Anastasius III., Roman.....	911
Simplicius, native of Tibur.....	467	Lando, native of Sabina.....	913
Felix III., Roman.....	483	John X., Roman.....	914
Gelasius I., Roman.....	492	Leo VI., Roman.....	928
Anastasius II., Roman.....	496	Stephen VIII., Roman.....	929
Symmachus, native of Sardinia.....	498	John XI.....	931
SIXTH CENTURY.		Leo VII., Roman.....	936
Hormisdas, native of Frusino.....	514	Stephen IX., Roman.....	939
John I., Tuscan.....	523	Martin III., (called by some Marinus II.).....	943
Felix IV., native of Beneventum.....	526	Agapetus II.....	946
Boniface II., Roman.....	530	John XII., Ottaviano Conti.....	956
John II., Roman.....	532	He was the first who changed his name on his elevation.	
Agapetus I., Roman.....	535	(Leo VIII., antipope).....	963
Sylvester, native of Campania.....	536	Benedict V., Roman.....	964
Vigilius, Roman.....	540	John XIII., Roman.....	965
Pelagius I., Roman.....	555	Benedict VI.....	972
John III., Roman.....	560	Domnus II., Roman.....	973
Benedict I., Roman.....	574	Benedict VII. (Conti), Roman.....	974
Pelagius II., Roman.....	578	John XIV.....	983
Gregory I., Roman, styled 'the Great,'.....	590	(Boniface VII., Franco, antipope.)	
SEVENTH CENTURY.		John XV., Roman.....	985
Sabinianus, native of Tuscany.....	604	John XVI., Roman.....	986
Boniface III., Roman.....	607	Gregory V., German.....	996
Boniface IV., native of Abruzzi.....	608	Sylvester II., Gerbert, native of Auvergne.....	999
Deusdedit or Deodatus I., Roman.....	615	ELEVENTH CENTURY.	
Boniface V., Neapolitan.....	619	John XVII., (May—October).....	1003
Honorius I., native of Capua.....	625	John XVIII., Roman.....	1003
Severinus, Roman.....	638	Sergius IV., Roman.....	1009
John IV., native of Dalmatia.....	640	Benedict VIII., native of Tusculum.....	1012
Theodorus I., Greek.....	641	John XIX., Roman (in some catalogues reckoned XX.; the	
Martin I., native of Tudertum.....	649	diversity arising from a disputed election).....	1024
Eugenius I., Roman.....	654	Benedict IX.....	1033
Vitalianus, native of Signia.....	657	(Sylvester, antipope.)	
Deusdedit II., Roman.....	672	Gregory VI., Roman.....	1044
Domnus I., Roman.....	676	Clement II., native of Saxony.....	1047
Agathon, Sicilian.....	678	Damasus II. (Poppo).....	1048
Leo II., Sicilian.....	682	Leo IX., Bishop of Toul.....	1049
Benedict II., Roman.....	684	Victor II., Bishop of Eichstadt.....	1055
John V., native of Syria.....	685	Stephen X., Frederick, Abbot of Monte Casino.....	1057
Conon, native of Thrace.....	686	Benedict X., by some styled antipope, abdicated.....	1058
Sergius I., native of Palermo.....	687	Nicholas II., native of Burgundy.....	1059
EIGHTH CENTURY.		Alexander II., native of Milan.....	1061
John VI., native of Greece.....	701	Gregory VII., Hildebrand, native of Tuscany.....	1073
John VII., native of Greece.....	705	(Guibert, antipope, assumed the name of Clement III.)	
Sisinius, native of Syria.....	708	Victor III., native of Beneventum.....	1086
Constantine, Syrian.....	708	Urban II., native of France.....	1088
Gregory II., Roman.....	715	Paschal II., native of Tuscany.....	1099
Gregory III., Syrian.....	731	(Albert and Theodoric, antipopes.)	
Zacharias, Greek.....	741	TWELFTH CENTURY.	
Stephen II.....	753	Gelasius II., native of Caleta.....	1118
Stephen III., Roman.....	753	Callixtus II., native of Burgundy.....	1119
Paul I., Roman.....	757	Honorius II., Cardinal Lambert, Bishop of Ostia.....	1124
Stephen IV., Sicilian.....	763	Innocent II., Roman.....	1130
Adrian I., Roman.....	772	(Anacletus, antipope.)	
Leo III., Roman.....	795	Celestinus II., Tuscan.....	1143
NINTH CENTURY.		Lucius II., native of Bologna.....	1144
Stephen V., Roman.....	816	Eugenius III., native of Pisa.....	1145
Paschal I., Roman.....	817	Anastasius IV., Roman.....	1153
Eugenius II., Roman.....	824	Adrian IV., Nicholas Breakspear, Englishman.....	1154

John VIII., Roman.....	872	Innocent III., Cardinal Lotharius, native of Signia.....	1198
Martin II. (called also Marinus I.).....	882	THIRTEENTH CENTURY.	
Adrian III., Roman.....	884	Honorius III., Cardinal Savelli, native of Rome.....	1216
Stephen VI., Roman.....	885	Gregory IX., Cardinal Hugo, native of Anagni.....	1227
Formosus, Bishop of Porto.....	891	Celestinus IV., native of Milan.....	1241
(Sergius and Boniface VI., antipopes.)		Innocent IV., Cardinal Sinibaldo Fieschi, native of Genoa.....	1242
Stephen VII., Roman.....	896	Alexander IV., Cardinal Rinaldo Conti, native of Anagni.....	1254
Romanus, Tuscan.....	897	Urban IV., James, Patriarch of Jerusalem, Frenchman.....	1261
Theodorus II., Roman.....	897	Clement IV., Guy, native of St. Gilles, in Languedoc.....	1265
John IX., native of Tibur.....	897	Gregory X., Tebaldo Visconti, native of Piacenza.....	1272
		Innocent V., Cardinal Peter, native of Tarentaise.....	1276

Adrian V., Ottobono Fieschi, native of Genoa.....	1276
John XXI., native of Lisbon.....	1276
Nicholas III., Cardinal Orsini, native of Rome.....	1277
Martin IV., Cardinal Simon de Brie, Frenchman.....	1281
Honorius IV., Cardinal James Savelli, native of Rome.....	1285
Nicholas IV., Cardinal Jerome, native of Ascoli.....	1288
Celestinus V., Pietro, da Morrone of Abruzzi.....	1294
Boniface VIII., Cardinal Benedetto Gaetani, native of Anagni.....	1295

FOURTEENTH CENTURY.

Benedict XI., Cardinal Nicholas, native of Treviso.....	1303
Clement V., Bertrand of Bordeaux, removed the papal see to Avignon.....	1305
John XXII., James, native of Cahors, in France.....	1316
(Nicholas, antipope.)	
Benedict XII., James Fournier, Frenchman.....	1334
Clement VI., Peter Roger, native of Limoges, in France...	1342
Innocent VI., Stephen Aubert, native of Limoges.....	1352
Urban V., William Grimoard, Frenchman.....	1362
Gregory XI., Peter Roger, Frenchman, restored the papal see to Rome.....	1370
Urban VI., Bartolomeo Prignano, Neapolitan.....	1378
(From 1378 to 1410 occurs the great Western Schism, during which, in conflict with the line of popes inserted in the catalogue, is found a rival line residing at Avignon—Clement VII., 1378—1394; Benedict XIII., 1394—1410. The Council of Pisa, 1410, deposed both rival popes; but Benedict XIII. remained in schism till his death in 1424.)	
Boniface IX., Peter Tomacelli of Naples.....	1389

FIFTEENTH CENTURY.

Innocent VII., Cosmo Migliorati, native of Sulmona.....	1404
Gregory XII., Angelo Corradi, native of Venice.....	1406
Alexander V., Peter Philargius, native of Candia.....	1409
John XXIII., Cardinal Cossa, deposed by the council of Constance.....	1410
Martin V., Otto Colonna, Roman.....	1417
Eugenius IV., Gabriel Condulmero, Venetian.....	1431
(Felix, antipope.)	
Nicholas V., Cardinal Thomas, native of Sarzana.....	1447
Callixtus III., Alfonso Borgia, Spaniard.....	1455
Pius II., Eneas Sylvius Piccolomini, native of Siena.....	1458
Paul II., Peter Barbo, native of Venice.....	1464
Sixtus IV., Francis della Rovere, Genoese.....	1471
Innocent VIII., Gian Battista Cibo, Genoese.....	1485
Alexander VI., Rodrigo Lenzoli Borgia, Spaniard.....	1492

SIXTEENTH CENTURY.

Pius III., Francis Todeschini Piccolomini.....	1503
Julius II., Julian della Rovere, Genoese.....	1503
Leo X., Giovanni de' Medici, son of Lorenzo the Magnificent.....	1513
Adrian VI., native of Utrecht.....	1522
Clement VII., Giulio de' Medici, nephew of Lorenzo.....	1523
Paul III., Alessandro Farnese, native of Rome.....	1534
Julius III., Giovan Maria Giocci, native of Rome.....	1550
Marcellus II., Cardinal Cervini, native of Montepulciano...	1555
Paul IV., Gianpietro Carafa, Neapolitan.....	1555
Pius IV., Giovanni Angelo Medichini, native of Milan.....	1559
Pius V., Michele Ghislieri, native of Alessandria.....	1566
Gregory XIII., Hugo Buoncompagni, native of Bologna.....	1572
Sixtus V., Felice Peretti of Montalto, native of the March of Ancona.....	1585
Urban VII., Gian Battista Castagna, Genoese.....	1590
Gregory XIV., Nicola Sfondrati, native of Milan.....	1590
Innocent IX., Gian Antonio Fecchinetti, native of Bologna...	1591
Clement VIII., Ippolito Aldobrandini, native of Fano.....	1592

SEVENTEENTH CENTURY.

Leo XI., Alessandro de' Medici, native of Florence.....	1605
Paul V., Camillo Borghese, native of Rome.....	1605
Gregory XV., Alessandro Ludovici, native of Bologna.....	1621
Urban VIII., Maffeo Barberini, Florentine.....	1623
Innocent X., Gian Battista Pamfilj, native of Rome.....	1644
Alexander VII., Fabio Chigi, native of Siena.....	1655
Clement IX., Giulio Rospigliosi, native of Pistoia.....	1667
Clement X., Emilio Altieri, native of Rome.....	1670
Innocent XI., Benedetto Odescalchi, native of Como.....	1676
Alexander VIII., Pietro Ottoboni, native of Venice.....	1689
Innocent XII., Antonio Pignatelli, native of Naples.....	1691

EIGHTEENTH CENTURY.

Clement XI., Gian Francesco Albani, native of Urbino.....	1700
Innocent XIII., Michael Angelo Conti, native of Rome.....	1721
Benedict XIII., Vincenzo Maria Orsini, native of Rome.....	1724

Clement XII., Lorenzo Corsini, native of Florence.....	1730
Benedict XIV., Prospero Lambertini, native of Bologna.....	1740
Clement XIII., Carlo Rezzonico, native of Venice.....	1758
Clement XIV., Gian Vincenzo Ganganelli, born near Rimini...	1769
Pius VI., Angelo Braschi, native of Cesena.....	1775

NINETEENTH CENTURY.

Pius VII., Gregorio Barnaba Chiaramonti, native of Cesena.....	1800
Leo XII., Annibale della Genga, native of Romagna.....	1823
Pius VIII., Cardinal Castiglioni, native of Cingoli.....	1829
Gregory XVI., Mauro Cappellari, native of Belluno.....	1831
Pius IX., Giovanni Maria Mastai-Ferretti, nat. of Sinigaglia.....	1846
Leo XIII., Gioacchino Pecci, native of Carpi.....	1878

Protestants generally object to the list of popes given by Roman Catholics, that there is no absolutely conclusive evidence of the apostle Peter's ever having been at Rome; although most of them admit the probability that he was there, and suffered martyrdom there. But they deny that there is any evidence whatever of his having exercised the office of bishop either there or anywhere else. They call in question many other of the names and dates in the earlier part of the list, not so much disputing the existence of the persons named, as their exercise of the office of bishop in Rome, and still more their right to be considered bishops of Rome. According to Protestants in general, the papacy grew by a gradual assumption of power out of an ordinary bishopric, through the advantage of metropolitan position and influence, and was afterwards supported by the fable—as they deem it—of the see of St. Peter.

POPE. See RUFFE.

POPE, ALEXANDER, an eminent English poet, was born in London, May 21, 1688. His parents were Roman Catholics, and to this faith the poet also nominally adhered, thus debarring himself from public office and employment. His father, a linen-merchant, saved a moderate competency, and received some accession of fortune by his marriage with Edith Turner, his second wife, and the poet's mother, a lady of a good Yorkshire family. He then withdrew from business, and settled on a small estate he had purchased at Binfield in Windsor Forest. He died at Chiswick, in 1717. His son shortly afterwards took a long lease of a house and five acres of land at Twickenham, on the banks of the Thames, whither he retired with his widowed mother, to whom he was tenderly attached, and where he resided till his death, cultivating his little domain with exquisite taste and skill, and embellishing it with a grotto, temple, wilderness, and other adjuncts poetical and picturesque. In this famous villa, P. was visited by Frederick, Prince of Wales, and by the most celebrated wits, statesmen, and beauties of the day, himself being the most popular and successful poet of his age.

P.'s early years were spent at Binfield, within the range of the Royal Forest. He received some education at little Catholic schools, but was his own instructor after his twelfth year. He never was a profound or accurate scholar, but he read the Latin poets with ease and delight, and acquired some Greek, French, and Italian. He was a poet almost from infancy; he 'lisped in numbers,' and when a mere youth, surpassed all his contemporaries in metrical harmony and correctness. His pastorals and some translations appeared in Tounson's *Miscellany*, in 1709; but were written three or four years earlier. These were followed by the *Essay on Criticism*, 1711; *Rape of the Lock* (when completed, the most graceful, airy, and imaginative of his works), 1712—1714; *Windsor Forest*, 1713; *Temple of Fame*, 1715. In a collection of his works printed in 1717, he included the *Epistle of Eloisa*, and *Elegy on an Unfortunate Lady*, two poems inimitable for pathetic beauty and finished melodious versification. From 1715 till 1726, P. was chiefly engaged on his translations of the *Iliad* and *Odyssey*, which, though wanting in true Homeric simplicity, naturalness, and grandeur, are splendid poems. They realized to the fortunate and fashionable translator a sum of about £8000. He next edited an edition of Shakspeare, which proved unworthy of his reputation. In 1728—1729, he published his greatest satire—the *Dunciad*, an attack on all poetasters and pretended wits, and on all other persons against whom the sensitive poet had conceived any enmity. In 1737, he gave to the world a volume of his *Literary Correspondence*, containing some pleasant gossip and observations, with choice passages of description; but it appears that the correspondence was manufactured for publication, not composed of actual letters addressed to the parties whose names are given, and the collection was introduced to the public by means of an elaborate stratagem on the part of the scheming poet.

Between the years 1731 and 1739, he issued a series of poetical essays, moral and philosophical, with satires and imitations of Horace, all admirable for sense, wit, spirit, and brilliance. Of these delightful productions, the most celebrated is the *Essay on Man*, to which Bolingbroke is believed to have contributed the spurious philosophy and false sentiment; but its merit consists in

detached passages, descriptions, and pictures. A fourth book to the *Dunciad*, containing many beautiful and striking lines, and a general revision of his works, closed the poet's literary cares and toils; he died on the 30th of May 1744, and was buried in the church at Twickenham. P. was of very diminutive stature, and deformed from his birth. His physical infirmity, susceptible temperament, and incessant study, rendered his life 'one long disease.' He was, as his friend, Lord Chesterfield, said, 'the most irritable of all the *genus irritabile vatum*, offended with trifles, and never forgetting or forgiving them.' His literary stratagems, disguises, assertions, denials, and (we must add) misrepresentations, would fill volumes. Yet P., when no disturbing jealousy, vanity, or rivalry intervened, was generous and affectionate, and he had a manly, independent spirit. As a poet, he was deficient in originality and creative power, and thus was inferior to his prototype, Dryden; but as a literary artist, and brilliant declaimer, satirist, and moralizer in verse, he is still unrivalled. He is the English Horace. Of the many lives, that by Carruthers is one of the best (1857); see also that by Leslie Stephen (1880).

POPERINGHE, an old commercial town of Belgium, in the province of West Flanders, four miles from the French frontier. The town has manufactures of lace, linens, and woollen cloths. Pop. 11,000.

PO'PERY literally means attachment to the religion or to the party of the pope; and in this sense the word is synonymous with the profession of the Roman Catholic religion. In its use, however, it has come to involve the idea of contempt or disparagement. It may therefore be said, that the word is either intended to designate what are regarded by Protestants as the most exaggerated and superstitious among the doctrines and practices which they ascribe to Catholics, in contradistinction to the belief of the more moderate members of that church, or is designedly employed as an expression of contempt and depreciation.

POPISH PLOT, the name given to an imaginary plot, on the part of the Roman Catholics in England during the reign of Charles II., the object of which was believed to be a general massacre of the Protestants. See **OATES**, **TITUS**.

PO'PLAR (*Populus*), a genus of trees, forming, along with willows, the whole of the natural order *Salicaceæ* or *Salicinae* (by some regarded as a sub-order of *Amentaceæ*), and having dioecious flowers arranged in catkins, both male and female flowers with an oblique cup-shaped perianth. The seeds have silky hairs, as in willows, and are readily wafted about by the wind. The species are numerous, chiefly natives of the temperate and cold regions of the northern hemisphere. They are large trees of rapid growth, with soft wood; and broad, heart-shaped, ovate, triangular, or lozenge-shaped, deciduous leaves, on rather long stalks. Many of them are very beautiful trees. The catkins appear long before the leaves, and proceed from distinct lateral buds. Few of the poplars are of much value for their timber, which is generally white, soft, and light; but from their rapid growth, they are useful as yielding firewood, where the scarcity of other fuel renders it necessary to plant trees for this purpose, and they are often planted as ornamental trees, producing an immediate effect of embellishment in a bare situation more readily than almost any other kind of tree. Besides the species known by the name *Aspen* (q. v.), or Tremulous Poplar, the following seem the most worthy of notice.

The **WHITE P.**, or **ABELE** (*P. alba*), a native of the southern parts of Europe, and reckoned among British trees, but probably not indigenous in Britain, is a tree of 80 feet or upwards; with a fine spreading head; and roundish, heart-shaped, lobed, and toothed leaves, which are smooth, shining, and dark-green above, downy and silvery-white beneath. The wood is used by cabinet-makers, turners, and toy-makers. It is little liable to swell or shrink, which adapts it for various purposes. The tree loves low situations and clay soils. This tree has of late years suffered in Britain from some unknown cause, like the potato, dying where it previously flourished; whilst other poplars, the most nearly allied, continue to flourish in the same localities.—The **GRAY P.** (*P. canescens*) is very similar to the White P., but of more vigorous growth, a large spreading tree; the leaves similar to those of the White P., but not so dark-green above or so white beneath. It is not of so rapid growth as the White P.; and its wood is harder and better, makes good flooring, and is preferable to pine-deal for the neighborhood of fireplaces, being less apt to take fire; it is also used for coarse doors, carts, barrows, &c., and not being liable to warp, is esteemed by wood-carvers. The tree generally begins to rot in the heart when forty or fifty years old. Like most of the other poplars, it fills the ground around it with suckers. Like the White P., it is a very doubtful native of Britain, and belongs to the center and south of Europe.—The **BLACK P.** (*P. nigra*), a native of most parts of Europe, and perhaps of England, is a tree of 50–80 feet high, with an ample spreading head, viscous leafbuds, and deltoid or unequally quadrangular, perfectly smooth leaves.

The wood is used for the same purposes as that of the White and Gray Poplars. The 'cotton' from the seeds has been used in France and Germany for making cloth hats and paper, but

Black Poplar (*P. nigra*).

these uses of it were not found profitable.—The **LOMBARDY P.** (*P. fastigiata* or *dilatata*) is perhaps a mere variety of the Black P., with erect instead of spreading branches. It appears to have been introduced into Europe from the East. It is very common in the Punjab and in Persia, and now also in Lombardy and other parts of Italy. It attains a height of 100, or even 150 feet, and is remarkable for its erect form, contracted head, and very rapid growth. It is often planted as an ornamental tree, although not so generally as in the end of last century, when it was thought preferable for ornamental purposes to every other tree. It is common in the streets and squares of towns in all parts of Britain; and is particularly adapted to situations where a long horizontal line of any kind fatigues the eye, or as seen starting up from a mass of lower wood or shrubbery, but has a besom-like appear-

Lombardy Poplar (*P. fastigiata*).

ance when planted in unsuitable situations. The wood is of almost no value. It is generally propagated by layers.—The species commonly known as **BLACK ITALIAN P.** (*P. monilifera* or *aculeata*), although it is really a native not of Italy, but of North America, and is sometimes more correctly called **CANADIAN P.**, the female catkins of which resemble a string of pearls, is frequently planted both as an ornamental tree and for the sake of its timber, which is useful for flooring, &c. The leaves are deltoid. It is of very rapid growth, and attains a height of 100–120 feet.

The **BALSAM P.**, or **TACAMAHAC** (*P. balsamifera*), a very common ornamental tree in Britain, is a native both of North America and of Siberia, and has whitish ovate-oblong leaves, which in spring are of a delicate yellow tint, and have an agreeable fragrance. The leaf-buds are viscid. The erect, fastigate manner of growth approaches that of the Lombardy Poplar. The resinous exudation of the buds (*Tacamahac*) is said to be diuretic and anti-spasmodic; and an ointment made from the buds is used for tumors, wounds, and burns. The resinous exudation of the buds of other species, as the Black P., possesses similar properties.—The **COTTON-WOOD** (*P. Canadensis*) of North America, particularly abundant on the upper parts of the Mississippi and Missouri, is valued as a timber tree, and has been pretty extensively planted

in Britain; as has also the *ONTARIO P.* (*P. candicans*), a species with the same balsamic character as *P. balsamifera*, and chiefly distinguished from it by its larger leaves. In size of leaf, no other species equals *P. heterophylla*, a native of the Southern States of North America, the leaves of which are often six inches long.

PO'PLIN (Fr. *papeline*). In the 15th c., a fabric was woven in Avignon called *papeline*, which was made of silk, and was much esteemed. An attempt to imitate it was introduced into England, and the name was corrupted to *poplin*, which has been adopted abroad as well as at home. In 1775, the manufacture was introduced to Ireland by French Protestant refugees, and from that time to the present, Irish poplins have been famous. What the exact nature of the original *papelines* was, is not certainly known; but the best modern poplins consist of a warp of silk and a weft of worsted, which gives substance, combined with great softness and elasticity, to the material. Cotton, and even flax yarns are substituted for silk, wholly or partially, in making cheap goods, but they are very far inferior in beauty to the true poplins.

POPOCATEPE'TL (Aztec, *popoca*, to smoke, and *tepetl*, a mountain), or in Spanish, *Volcan Grande de Mexico*, Grand Volcano of Mexico, a mountain about 10 miles south-west of the city of Mexico. It rises in the form of a cone to a height of 17,720 feet above the sea-level, and is composed chiefly of porphyritic obsidian. Forests girdle its lower parts; but at an elevation of 13,000 feet, all vegetation ceases. About the period of the Spanish conquest, it was very active, but no eruption has been recorded since 1540. It still smokes, however. Cortes, the conqueror of Mexico, attempted to reach its summit, but was unable to do so, on account of the masses of snow that covered it. This feat was first achieved by Francisco Maniño, one of Cortes's followers, who not only climbed to the top of the mountain, but had himself let down its crater, by means of ropes, to a depth of about 450 feet. In 1827, it was again scaled by the brothers Glennie, who determined its altitude barometrically, and since then this laborious exploit has been several times performed, and even by ladies.

PO'PINJAY, a name of the Green Woodpecker (*Picus viridis*), a bird common in most of the wooded districts of England and Scotland. See **WOODPECKER**.

PO'PPY (*Papaver*), a genus of plants of the natural order *Papaveraceae*, having a calyx of two (or rarely three) sepals, which very soon fall off; a corolla of four (rarely six) petals; numerous stamens seated on a receptacle; the stigma crowning the germen, without a style, and in the form of 4–20 rays; the capsule opening by pores under the persistent stigma, imperfectly divided into cells by partitions as numerous as the rays of the stigma, but which do not reach the center, the seeds extremely numerous. There are numerous species of *P.*, mostly natives of Europe and Asia, some of them found even in very northern regions, but most of them in the warmer temperate parts. They are rather large herbaceous plants, annual or perennial, mostly sprinkled with bristly hairs. They have a white milky juice; a disagreeable narcotic smell, particularly when bruised; pinnatifid or bipinnatifid leaves, more rarely jagged or toothed leaves; and large showy flowers, which readily become double by cultivation. The capsules are curious from the manner in which they fling out their seeds when the plant is shaken by the wind; each capsule being somewhat like a round or oval pepper-box, with holes, however, not in the top, where rain might get in by them, but under the rim. By far the most important species is that known as the *OPIMUM P.* (*P. somniferum*), also called the *WHITE P.*, and the *OIL POPPY*. See **OPIMUM**. But the same species is important on account of the bland fixed oil of the seeds, and is much cultivated as an oil-plant. *P. oil* is as sweet as olive oil, and is used for similar purposes. It is imported into Britain in considerable quantities from India. The *P.* is also extensively cultivated for it in France, Belgium, and Germany.

The use and manufacture of this oil were for a long time, during last century, strictly prohibited in France, from a mistaken notion that it must partake of the narcotic properties of the milky juice of the plant. The seed, however, contains no opium or any narcotic principle, and was well known to the ancients as a pleasant article of food, fit to be eaten by itself or with bread. The oil expressed from it is perfectly wholesome, and is much used in France and elsewhere as an article of food. Fully one-half of the oil used for cooking and otherwise for alimentary purposes in France, is of this kind. The seeds yield about 40 per cent. of oil, and the oil-cake is useful for manure or for feeding cattle. The oil is sometimes used by painters and by soap-boilers; but it is not good for burning. In the cultivation of the *P.* for oil, the seed is often sown in autumn, where the severity of winter-frosts is not to be feared; in more northern parts, it is sown in the spring, and sometimes the seed is scattered on the top of the snow with which the ground is covered. Being very small, it needs little or no harrowing. Early sowing is favorable

to the size of the plant, and the abundance of produce. Hoeing and thinning are advantageous. An open but rich soil is best for the *P.*; and a sheltered situation is necessary, as in exposed situations, much of the seed is scattered by the wind. The *P.* does not exhaust the land so much as colza, rape, and some other oil-plants. Harvesting ought to begin when one-fourth of the capsules of each plant are open. It is accomplished by pulling the plants in such a manner as not to shake the seed out of the capsules, and tying them in sheafs, which are placed together in an erect or slightly sloping position, till the ripening of the capsules is completed, when the seed is taken out by shaking the capsules into a tub or on a cloth, great care being used to prevent any earth from the roots from getting mixed with them. Some farmers in Flanders sow *P.* in alternate rows with carrots.

The variety of *P.* chiefly cultivated as an oil-plant has flowers of a dull reddish color, large oblong capsules, and brownish seeds; but the white-flowered variety, with globular capsules and white seeds, is also used.—The *ORIENTAL P.* (*P. orientale*), a native of Armenia and the Caucasus, a perennial species, is often planted in gardens on account of its very large, fiery-red flowers. Its unripe capsules have an acrid, almost burning taste; but are eaten by the Turks, and opium is extracted from them.—Several species are British, all of them local, rare in some places, and troublesome weeds in cornfields in other places apparently quite similar in climate. Among them is the *CORN P.* or *COMMON RED P.* (*P. rhoeas*), with bright red flowers, and deeply pinnatifid leaves. The petals are mucilaginous and slightly bitter; they have a slight narcotic smell; and a syrup made of them is sometimes used as an anodyne in catarrhs and children's complaints; but they are more valued for the rich red color which they yield. A variety with double flowers is cultivated in flower-gardens, under the name of *Carnation Poppy*. Among the ancients, the *P.* was sacred to Ceres.

POPPY-HEAD, a carved ornament, used as a finial on top of bench-ends, &c. In early examples, it is a simple fleur-de-lis, but in late Gothic, this and other wood-work becomes very elaborately carved.

POPULATION, as a study, comprehends those general laws that govern the increase or decrease of the human race, and the checks which modify them. The practical object of the investigation is to regulate the operation of the laws so as to promote the welfare of society. Malthus was the first to formulate the great law of the dependence of the increase of population on the means of its subsistence (see **MALTHUS**). The varying rate of increase in different countries makes it a subject which requires to be investigated under different heads. For those laws affecting it through the relations of births, deaths, and marriages, see **VITAL STATISTICS**.

PO'RCELAIN. See **POTTERY**.

PORCH, a building forming an enclosure or protection for a doorway. Every one knows how much this beautiful feature is now used, and how efficient it is as a protection from the wind

Porch of Aldham, Essex (1350).

(From Parker's Glossary of Architecture.)

and weather. In Elizabethan and medieval architecture, the porch was also very common in domestic architecture. In churches, it was almost universal in this country. In France, many splendid porches or portals remain; they are amongst the most beautiful specimens of medieval art. In England, wooden porches, of picturesque structure, are very common in the parish churches of the middle ages.

PO'RCUPINE (*Hystrix*), a genus of mammalia, of the order *Rodentia*, and family *Hystriidae*. This family is remarkably characterized by an armature of spines, which, like those of the

hedgehogs, are, as to their structure, merely thick and strong hairs. The *Hystricida* are plantigrade; the fore-feet have four toes and a rudimentary thumb, the hind-feet have five toes. Their general aspect is heavy and pig-like, and they have a grunting voice. The muzzle is broad and blunt; the ears short and rounded; the incisors smooth and large, two above, and two below; the molars eight above, and eight below. The name porcupine is derived from the French words *porc*, a hog, and *épin*, a spine.—The COMMON P. (*H. cristata*) is a native of the south of Europe, of many parts of Asia, and of most parts of Africa. It is one of the largest of rodents, being from two to three feet in length, besides the tail, which is about six inches long. The hinder part of the head and the neck are furnished with a crest of long bristles, capable of being elevated or depressed at pleasure. The muzzle and limbs are covered with very short hair; the back

Porcupine (*Hystrix cristata*).

and sides with spines, which are longest on the middle of the back, where they are almost of the thickness of a goose-quill, and more than a foot long. The spines are supported by a slender pedicle, and they terminate in a sharp point; they are longitudinally striated, and are ringed with black and white, which gives a general gray color to the animal. Their ordinary position is flat, with the points directed backwards; but when the animal is excited, they are erected, and it rolls itself up like the hedgehog, with spines pointing in every direction.

The tail spines or quills are of very singular structure, being open thin-sided tubes, about two inches long, supported upon slender flexible pedicles; and they make a sound by rattling together when the tail is shaken. The P. is said to rattle also the spines of its body when irritated, but this is doubtful. The statement has been often made, that it throws off its spines or quills by a voluntary act, launching them at its adversaries; but it has no such power, although it is possible that quills ready to come off may be detached in moments of excitement, and fly to a small distance with sufficient force to be annoying to a pursuer. The P.'s armor, however, is strictly defensive, and it seeks to turn its back, and thus the points of its spines to an enemy. It is a solitary and nocturnal animal. It burrows in the ground, and in winter it becomes torpid. It feeds on roots, bark, fruit, and other vegetable substances, sometimes committing great depredations in gardens. The spines or quills of the P. are used for various purposes, and have a certain commercial value. It is chiefly sought on account of them; although its flesh is eaten, and was brought to the market of ancient Rome.—A larger species of P. (*H. leucurus*), with the quills of the tail quite white, is found in India, and other species inhabit different parts of the East. The ATHERURE, or TUFTED-TAILED P. (*Atherura fasciculata*, a native of India and Malacca, differs from the true porcupines in the head and muzzle not being convex, in having the quills flattened like blades of grass, and those of the tail gathered into a tuft at the end of it. The Canada P., or Urson (q. v.), is still more different from the true porcupines; and the Coeudus (*Syntheres*) of the warm parts of America—which are covered with short quills, and, like the urson, live among the branches of trees—are remarkably distinguished by their long prehensile tail.

PORDENONÉ, a town of Italy, in the province of Udine, 40 miles N.N.E. of Venice, on a plain near the base of the Alps. Pop. 5000.

POR'IFERA (Lat. *poro-bearing*) is the term employed by Dr. Grant to designate the class *Spongia*, or *Sponges*, in consequence of the appearance which the members of this class present when a section is made through their tissue. The term *Spongia* is used in preference by many naturalists.

PO'RISM, a kind of geometric proposition in high favor among ancient Greek mathematicians, but of which the notices that have come down to us are so few and meagre, that, till lately, mathematicians were not agreed about what a porism really was. The ancient works in which porisms are mentioned are the *Collectiones Mathematicae* of Pappus, and the *Commentarii* of Proclus. Dr. Robert Simson (q. v.) was the first to restore the probably origi-

nal form of porisms. As defined by Playfair, 'a porism is a proposition affirming the possibility of finding such conditions as will render a certain problem indeterminate, or capable of innumerable solutions.' Good examples of porisms are given in Simson's *Opera Reliqua*; Playfair's 'Origin and Investigation of Porisms' (*Trans. of Roy. Soc. of Edin.*, vol. iii.); Wallace's paper, 'Some Geometrical Porisms, &c.' (*Edin. Trans.*, vol. iii. &c.)

PORK (Fr. *porc*, a hog, from Lat. *porcus*). The flesh of swine forms a very large portion of the animal food of most nations, although it is not the most nutritive, as will be seen by the following comparison of the four principal kinds of flesh-food:

	Mineral Matter.	Gelatine.	Fibrine and Albumen.	Fat.	Water.
Veal	4.5	7.5	9.0	16.5	62.5
Beef	5.0	7.0	8.0	30.0	50.0
Mutton...	3.5	7.0	5.5	40.0	44.0
Pork	1.5	5.5	4.5	50.0	38.0

It has qualities, however, which especially fit it for man's use; its fatness makes it a very heat-giving food for cold and temperate climates; whilst it surpasses all other kinds of animal food in the ease with which it may be preserved by salting and drying. Hence the trade in pork is considerable in all countries where it is used, but especially so in Great Britain and America, where vast quantities are cured for the supply of ships and the army, and for home use.

The quantity of pork imported into Britain (of which the greater part comes from the United States) is prodigious; in 1875, the value of the bacon and hams imported amounted to £6,955,200, besides pork to the value of £594,386. Millions of hogs are raised in the state of Ohio, and the curing of swine's flesh is the staple business of Cincinnati and other towns. A more vivid idea of the extent of this vast trade cannot be given than a recent statement of the *Louisville Gazette*, that 'there were between five and six acres of barrelled pork piled up three tiers high, in open lots, and not less than six acres unpiled, which would cover eighteen acres if closely laid in a single tier on the ground; besides all which, six acres of pens were filled with hogs waiting to be killed.' America has long furnished the chief supply of mess and common pork not only for the British army, navy, and mercantile marine, but also for those of most European nations. Next to America, Ireland, and especially the neighborhood of Cork, furnishes the largest supply of cured pork; and London and Wiltshire, and other parts of England, also furnish vast quantities of bacon and hams for general consumption.

PORO'SITY. By this term we express the experimental fact, that no kind of matter completely fills the space it occupies; in other words, that all bodies are full of minute cavities or interstices, such as are illustrated on a large scale by a sponge. On the atomic theory, it is obvious that this must be the case if the atoms of matter are spherical, or, indeed, if they have any form save one or two special ones, such as cubes or rhombic dodecahedrons. It is commonly asserted that all bodies must be porous, because they are compressible; but this is a great mistake, since we have no reason to believe that matter is not *per se* compressible, independently of the existence of interstices. The Florentine Academicians, in their attempts to compress water, proved the porosity of silver, by flattening a sphere of that metal, filled with water, and soldered. The water escaped through the pores of the silver, and stood in fine drops on its surface. The porosity of liquids is easily shown by mixing alcohol and water. The bulk of the mixture is considerably less than the sum of the bulks of the components, showing that these must in part have entered each other's pores. This property of matter is of great importance in natural phenomena, as it brings the molecular forces of capillarity into play: raising the sap in vegetables, allowing rain to sink into the ground, &c.

PORPHYRIUS, one of that series of ancient philosophers to whom is due the reformation of the Greek philosophy known as Neo-Platonism, was probably born at Batanea in Syria (the Bashan of Scripture) in the year 238 A.D. His original name was Malchus, the Greek form of the Syro-Phœnician *Melech*, or king. The name by which he is known in history, *Porphyrius*, 'one clad in purple,' is but a Greek epithet intended as a sort of paraphrase of his name. He is said by Socrates, the historian, and by St. Augustine, to have been originally a Christian; but this seems improbable, although it is certain that in his youth he was a hearer of Origen, or at least held some intercourse with him at Cæsarea in Palestine. What is more certain is, that he passed at a later time to Athens, where he studied rhetoric under Longinus, the well-known author of the treatise *On the Sublime*. It was at

Rome, however, whither he repaired soon after 260, that he entered upon what must be regarded as, historically considered, the career of his life. Here he became a scholar of the Neo-Platonist Plotinus, with whom, as well as with another member of of the same school, named Amelius, P. entered into an animated controversy, but eventually adopted so fully the opinions of Plotinus, that he became himself, if not the leader of the school, at least the most trusted of the disciples of its master. After six years' residence in Rome, he went to Sicily, where, if St. Jerome's account is to be relied on, he wrote his once celebrated treatise in 15 books against the Christians, now known only from the replies which it elicited, having been burned by order of the Emperor Theodosius. From Sicily, he went to Carthage, and afterwards to Athens; but eventually, Plotinus having died soon after P. left Rome, he returned to that city, where he continued to teach, as it would seem, until his death, which was probably about 305 or 306. For a view of P.'s position in the history of the Neo-Platonic school, see NEO-PLATONISTS. P. was a very voluminous writer. Of his works, the titles of more than 60 are still preserved, 43 of which are entirely lost. His *Life of Pythagoras*; his work *On Abstinence from Animal Food*; his *Commentary on Aristotle's Categories*, with the *Introduction*; and *On the Harmonies of Ptolemy*; and the book *Ad Marcellam*, addressed to his wife, are preserved entire. The rest are known chiefly by fragments, nor has any complete edition of his works been published.

PORPHYRY (Gr. purple), a term originally confined to an Egyptian rock used in sculpture, and known now as Rosso antico. It is composed, according to Delesse, of a red felspathic base, in which are disseminated rose-colored crystals of the felspar called oligoclase, with some plates of blackish hornblende, and grains of oxidized iron ore. The term is not now, however, used to denote any particular rock, but is applied to any rock which, like the Rosso antico, has a homogeneous earthy or compact base, through which are scattered distinct crystals of one or more minerals of contemporary origin with the base. Thus, gray volcanic trachyte often abounds in crystals of glassy felspar, forming a trachytic porphyry; or crystals of felspar, quartz, or calcareous spar, disseminated through a base of greenstone, form a greenstone porphyry. In the same way, there are pitchstone porphyry, basaltic porphyry, claystone porphyry, &c.

PORPOISE, or **PORPESSE** (*Phocæna*), a genus of Cetacea, of the family *Delphinidae*, having a form similar to the dolphins, but the muzzle short, uniformly convex, and without a beak; a dorsal fin; the teeth very numerous, simple, and equal. The **COMMON P.** (*P. communis*) is the most plentiful of the Cetacea on the Brit-

Porpoise (*Phocæna communis*).

ish coasts, abounding particularly on the western coasts of Ireland and of Scotland. It is found also on all the coasts of Europe from the Mediterranean northwards, on the coasts of North America, and in the arctic regions. It is one of the smallest of the Cetacea, its length sometimes not exceeding four feet, although individuals occur of six or even eight feet in length. The body is spindle-shaped; its greatest diameter is near the dorsal fin. The skin is perfectly smooth, and destitute of hair. There are from 40 to 50 teeth in each jaw, not conical, as in most of the Cetacea, but compressed. The eye is rather small, and the pupil in the form of a V. The opening of the ear is very minute, like a hole made with a pin. The blow-hole is crescent-shaped, with the horns of the crescent directed forwards, and is situated exactly over the eyes.

The P. is gregarious, and large numbers are often seen together, sometimes swimming in file, when their backs, appearing above the surface of the water, are apt to suggest the idea of a great sea-serpent; sometimes gambolling, either in fine weather, or when a storm is approaching, or even in the midst of a storm. The P. feeds on fish, which its teeth are admirably adapted to catch, and herds of porpoises pursue the vast shoals of herring, mackerel, &c., into bays and estuaries. The P. sometimes ascends rivers, apparently in pursuit of salmon, as far as the water is brackish, and is not unfrequently itself caught on such occasions. It is an object of pursuit on account of its skin, its oil, and its

flesh. The skin is nearly an inch thick, but is planed down until it becomes translucent, and is made into excellent leather, which is used for covering carriages and for other purposes. Little use is made of it in Britain, but it is used in America. Under the skin is a layer of fat, about an inch in depth, which yields oil of the finest quality. The flesh is dark-colored and bloody, but was in former times highly esteemed, and reckoned fit for the table of royalty, perhaps partly because among Roman Catholics it was accounted *fish*. In the time of Queen Elizabeth, it was still used by the nobles of England, and was served up with bread-crumbs and vinegar. It is now used only in very northern regions. It is a chief dainty of the Greenlanders.—The Grampus (q. v.) is commonly referred to this genus.—Another species of P. (*P. Capensis*) is found near the Cape of Good Hope.—The name P. is from the French *porc-poisson*, or the Italian *porco-pesce* (Hog-fish), corresponding to the French *marsoin* (Sea-hog) and the German *meerschwein*.

PORRI'GO. See **FAVUS** and **RINGWORM**.

PORSE'NNA, also **POR'SENA**, **LARS** or **LARTH** (*Lar*, in Etruscan means 'lord' or 'prince'), in the early and uncertain history of Rome, appears as a powerful king of Clusium in Etruria. According to the legend told by Livy for history, when Tarquin the Proud was expelled from Rome, he sought the help, first of the Veii and the Tarquinii (his Etruscan kinsmen), against his revolted subjects; but their efforts not proving successful, he turned to P., who willingly espoused his cause, and marched a great army against Rome. The Etruscan king seized the Janiculum, a fortified hill on the west side of the Tiber; and would have forced his way into the city across the 'Bridge of Wooden Piles' (*Pons Sublicus*), had not a brave Roman, Horatius Cocles, kept the whole of P.'s army at bay, while his comrades behind him hewed down the bridge; after which he plunged into the Tiber, and safely swam across its waves. P., we are informed, now laid siege to Rome; and after a while, the inhabitants began to suffer so severely from famine, that a desperate expedient was had recourse to. Three hundred of the noblest Roman youths swore to peril their lives in cutting off the Etruscan king. The first on whom the lot fell was C. Mucius, who stole into the camp of P., but not knowing the person of the king, killed his secretary instead. He was instantly seized, and put to the torture; but the unshrinking audacity with which he thrust his right hand into the fire and let it burn, moved the king so much, that he pardoned him; whereupon Mucius (ever afterwards called *Scævola*, 'the Left-handed') told him of the jeopardy in which he was placed. P. resolved to make peace with Rome at once, and his conditions, which were pretty favorable, being accepted by the sorely-pressed citizens, he withdrew his forces. This version of the story is wholly discredited by modern criticism, and is believed to have been invented by the patriotic annalists of ancient Rome to conceal the fact of a temporary Etruscan conquest, and the evidence in favor of this view is overwhelming.

Tacitus even expressly affirms that P. conquered the city; Dionysius informs us that the senate sent him an ivory sceptre, a golden crown, and a triumphal robe, which was the form that had been adopted by the Etruscan cities themselves of acknowledging the supremacy of the Roman king, Tarquinius Priscus; and Pliny mentions a circumstance which is quite conclusive as a proof of the subjugation of Rome—viz., that P. forbade the citizens to use iron, except for agricultural purposes. Niebuhr, who has placed this view beyond all doubt, notices various minor incidents which are perfectly unintelligible, except on the hypothesis of an Etruscan conquest. The whole details of the ancient legend, therefore, may be regarded as fabulous—the product of patriotic unverity—and what seems most reasonable to believe, is, that a great rising of the Etruscan against the Latin races took place, and that Rome, forming the Latin frontier towards Etruria, was exposed to the first brunt of the war, and suffered a disastrous defeat; but that shortly after, the Etruscans themselves were decisively beaten, and forced back into their own territories; for after the conquest of Rome, Aruns, a son of P., proceeded against Aricia, where (according to Livy) his army was routed under the walls of that city by the combined forces of the Latin cities, with the help of Greek auxiliaries from Cumæ. It is worth while quoting, as a proof of Niebuhr's wonderful talent for felicitous conjecture, that he explains the long-surviving Roman custom of beginning an auction by offering for sale the goods of King P., by the supposition, that in the recovery of their independence, the Romans probably captured property belonging to their late master, which they may have publicly sold. The sepulchre of P. at Clusium is described by Varro, but his description is not credible. The ancient legend has been magnificently rendered in modern verse by Macaulay. See the *Lays of Ancient Rome*.

PORSON, RICHARD, the greatest Greek scholar England has ever produced, was born on Christmas 1759, at East Ruston, Norfolk, where his father was parish clerk. The curate of the parish conceiving a liking for the boy, on account of his omnivor-

ous appetite for books and his marvelous memory, took charge of him, and had him educated along with his own sons. P. afterwards found a patron in Mr. Norris (the founder of the Norrisian professorship at Cambridge), who sent him to Eton in 1774, where he remained four years, but did not acquire any of the ordinary distinctions, although it is evident that it was there that his mind acquired a fixed bias towards classical studies. Another patron, Sir George Baker, sent him, in 1778, to Trinity College, Cambridge, of which he was elected a scholar in 1780. Next year he won the Craven Scholarship, and subsequently, the first Chancellor's medal. In 1782, he was chosen a fellow of Trinity. It was about this time that he began to give indications of his subtle sagacity and taste in the difficult verbal criticism of the Greek dramatists. For four years he contributed to *Maty's Review*—his first critique being on Schulz's *Æschylus*, and his finest on Brunk's *Aristophanes*. He also opened a correspondence with Professor Ruhnkens. If, however, we are to judge from a quatrain written at a later period of his life, he did more than correspond:

I went to Strasburg, where I got drunk
With that most learned Professor Brunk;
I went to Wurtz, and got more drunken
With that more learned Professor Ruhnkens.

In 1787 appeared, in the *Gentleman's Magazine*, his sarcastic letters on Hawkins's *Life of Johnson*. For the same periodical, he also wrote his far more famous and trenchant *Letters to Travis on the Three Witnesses*. The dispute concerned the genuineness of John i. 7, 8, and was occasioned by a blundering and pretentious defence of the passage by Archdeacon Travis, against the scornful attack of Gibbon. P. naturally incurred great odium on account of the side which he took in this controversy. One old lady who had him in her will for a legacy of £300, cut it down to £30, when she heard that he had written a book against Christianity.

In 1792, he resigned his fellowship, as he found that he could not conscientiously take orders in the church. Some of his friends now raised a fund to preserve him from want, and about £100 a year was secured. He was also appointed to the Regius professorship of Greek in the university of Cambridge—an office, indeed, only worth £40 a year; yet so splendid was his learning, so admirable his taste, so vigorous and epigrammatic his style of criticism, that he might easily have—by the exercise of a moderate degree of continuous literary labor—succeeded in gaining a handsome income. But already 'two devils had him in their grip'—procrastination and a raging thirst for drink—and they held him firm to the end of his melancholy career. The only thing he ever did in connection with his Greek professorship was to deliver a *proleptico* so excellent, that it has been said, if he had passed from verbal to æsthetic criticism, he would have surpassed all his countrymen in that too. In 1794, he edited the plays of *Æschylus* for the Foulis press, Glasgow; and between 1797 and 1801 four of Euripides, the *Hecuba*, the *Orestes*, the *Phænissæ*, and the *Medæa*. He also collated the Harleian MS. of the *Odyssey* for the *Greenleive Homer*. In 1806 he was appointed librarian of the 'London Institution' with a salary of £200; but was so grossly negligent of his duties, that the directors officially notified their dissatisfaction in these emphatic words: 'We only know that you are our librarian by seeing your name attached to the receipts for your salary.' He died of apoplexy, 25th September 1808, in the 49th year of his age, and was buried with great pomp in the chapel of Trinity College, Cambridge.

P.'s rage for drink was fearful. He would pour anything down his throat rather than endure the 'terrible torture of thirst.' Ink, spirits of wine for the lamp, an embrocation, are among the horrible things he is reported to have swallowed in his extremity. 'He used to return to the dining-room after the company had left it; pour into a tumbler the drops remaining in the wine-glasses, and drink off the collectanea.' In fact, his thirst was so outrageous, that P. cannot be considered a mere wilful drunkard; one must believe that he was driven into his excesses by some unknown disease of his constitution. See *POLYDIPSIA*. P.'s memory was as amazing as his thirst. The anecdotes told by his biographers almost surpass belief, yet are thoroughly authenticated. His critical acumen has never been matched in England. His tracts, reviews, letters, &c., were collected and edited, with a biographical notice, by Kidd, in six volumes. See 'Porsoniana' in *Rogers' Table-Talk*, and the Rev. J. Selby Watson's *Life of Richard Porson, M.A.* (1861).

PORT, in Naval Language, has at least three significations; first, a port is a harbor where ships are admitted to embark or discharge cargoes, or for other purposes—a free port being one in which the embarkation and discharge can be conducted without the payment of customs or port dues.—A port in a ship's side is the aperture for admitting light and air, or for pointing a gun through. See *PORT-HOLE*.—Port is also the official name for the left-hand side, when looking towards the bow of a ship—i. e., looking forwards. The term was, a few years ago, arbitrarily substituted for Larboard (q. v.).

PORT ARMS, in Musketry Drill, is derived from *portare*, to carry, and applies to a motion in which the fire-arm is brought to a slanting position in front of the body, lock to the front, the barrel crossing opposite the front of the left shoulder.

PORT-AU-PRINCE, or PORT-REPUBLICAN, the capital of Hayti (q. v.), is situated on the west coast, at the head of a bay of the same name, and has a fine appearance from the sea, but the interior is filthy in the extreme. The houses are chiefly of wood, and dungsteeds obtrude everywhere, even in the thoroughfares. The most notable buildings are the palace and the senate-house; other public edifices are the churches, a lyceum, college, custom-house, mint, and hospital. P. carries on a trade in mahogany, logwood, honey, coffee, cocoa, and rags. Pop. about 21,000. The town has suffered frequently from earthquakes.

PORT D'URBAN, or PORT NATAL, the only seaport of the colony of NATAL (q. v.).

PORT ELI'ZABETH, an important seaport of South Africa, commercial capital of the Eastern Province of the British colony of the Cape of Good Hope, stands on the western shore of Algoa Bay (q. v.), in lat. about 34° S., long. 25° 35' E. Many of the streets are elegant. One range of houses, consisting of four streets, which will bear comparison with the best streets in England, forms a continuous line two miles in length. In the style of the buildings, this town is superior to any other in South Africa. Its magnificent warehouses are constructed on a palatial scale, and resemble the finest in London, and its public buildings are all solid and substantial edifices. The principal are the town-house, 90 feet square and three stories high, containing the public library, the atheneum, and the municipal chambers; the public hospital, furnished with 100 beds; the Presbyterian and other churches, and the Roman Catholic cathedral. Its educational institutions are of a superior description. In 1854, under the auspices of Governor Sir George Grey, a system of schools was introduced known as the Grey Institute Schools, founded on a magnificent grant of town-lands, lately yielding a revenue of over £1000 per annum, and which affords a very excellent education at a very moderate charge. The chief of these are a high-school or college, and three elementary or district training-schools.

The town was founded in 1820, and the census of 1865 showed the population of the municipality of P. E. to be 8700; in 1878, it was close on 14,000. P. E. has made more rapid advancement than any other town in the colony; and the inhabitants are particularly notable for their enterprise and business energy. It owes its commercial importance in great part to the circumstance of its being the emporium of the great wool trade of the colony; and besides this it carries on a rapidly-increasing home and foreign trade. The transactions of its four banks are extensive. Two lines of railway run inland from Port E. The imports are valued at near £1,500,000 a year; and the exports about £2,000,000. As much as thirty or forty millions of pounds of wool may be exported in one year. The other colonial exports fall mainly under the heads of skins, hides, horns, ivory, and feathers.

The shore is open to the swell of the Indian Ocean, which often rolls in upon the beach with such violence that, until recently, cargoes could only be got to land by the use of surf-boats. Kaffirs, tempted by the high pay offered, used to come from a great distance to do the difficult and dangerous work of unloading the boats. But this system of landing is now in a great measure done away with, and ships now unload at several jetties. A breakwater has been constructed, and there are three lights for the direction of vessels.

PORT-GLASGOW, a parliamentary burgh and seaport of the county of Renfrew, Scotland, is situated on the Clyde, about 2 miles east of Greenock and 20 miles north-west of Glasgow. It was founded in 1668 by the magistrates of Glasgow as a harbor for the ships that belonged to or traded with their city—the Clyde at Glasgow being then inconveniently shallow, and the idea of deepening the river not having yet occurred. In 1695, the town and a small adjacent district were made into an independent parish; in 1710, it was constituted the principal custom-house on the Clyde, and for a while took the lead of Greenock; in 1775, it was incorporated as a municipality, and by the Reform Bill of 1832, it was raised to the rank of a parliamentary burgh, uniting with Kilmarnock, Rutherglen, Dumbarton, and Renfrew in electing a member of the legislature. P.-G. is rather a well-built town. The principal buildings are the town-house, custom-house, and churches of the different denominations. P.-G. has extensive manufactures of sail-ropes, chain-cables, several sugar-refineries, foundries, building-yards, commodious quays, and an extensive wet-dock. The deepening of the Clyde, enabling large vessels to ascend to Glasgow, seriously injured its commercial prosperity, but the trade has been for many years improving; the shipping employed is considerable. In 1876, 38 ships, of 17,066 tons, were registered at P.; and in the same year 53 vessels, of 27,406 tons, were built here. Pop. (1871) 9851; (1881) 10,801.

PORT LOUIS, the capital and principal port of the British colony of Mauritius, is situated on an inlet on the north-west coast. Its streets, though narrow, are straight, and are furnished with foot-paths and macadamized. It contains a number of public buildings, among which are a theater, library, hospital, and botanic garden. Its harbor is capacious, but is quite safe only during the fine season. The imports and exports of the colony are mainly transacted at P. L.; and their quantity, value, and character are mentioned under the article *Mauritius* (q. v.). Pop. of the port is estimated at 65,000 (1871).

PORT MAHON (anc. *Portus Magonis*), the capital of the island of Minorca (q. v.), is beautifully situated on a deep and narrow inlet in the south-east of the island. Its harbor, sufficiently spacious to accommodate a large fleet of men-of-war, is one of the finest in the Mediterranean, and is protected by three forts. It has no architectural features worthy of special notice, but is on the whole well built. The military governor and the bishop of the island reside here. The government buildings were constructed when Minorca was English. Pop. 13,000.

PORT PATRICK, a burgh of barony and small seaport of Scotland, in Wigtown, 8 miles S.W. of Stranraer, with which it is connected by rail. It was formerly a mail-packet station for Ireland; £250,000 were spent on government works, including a lighthouse, demolished in 1869. In Scotland, P. is the nearest point to Ireland, distant 21½ miles. Pop. (1871) 685; (1881) 591.

PORT PHILLIP. See MELBOURNE.

PORT ROYAL-DES-CHAMPS, a convent of Cistercian nuns, near Versailles, which obtained much celebrity during the 17th century. It was founded for nuns by a member of the family of Montmorenci, in the early part of the 13th c.; and soon after its establishment, obtained from the pope the privilege of receiving lay persons, who, without taking monastic vows, desired to live in religious retirement. This portion of the P. R. institute in later times became of great importance. The discipline of the convent having been much relaxed in the 15th and 16th centuries, one of its worst abuses—that of appointing the superior, not on account of fitness, but from considerations of family or other worldly or political motives—became in the end the occasion of its complete reformation. Angelique Arnauld, sister of the celebrated brothers Arnauld, was appointed, when a mere child, coadjutrix of the abbess, and on the death of this lady, although she was then only in her eleventh year, herself succeeded to the office. As Mère Angelique advanced in years, she felt moved, although still very young, by a profound sense of her responsibilities, and undertook a complete and rigid reformation of the community, which she carried out in all its details—as the strict observance of religious poverty, abstinence from meat, complete seclusion, and the most severe ascetic exercises. The community was removed to Paris in 1626, and in 1633 to a new convent, which was thenceforward called Port Royal-de-Paris; and from this time the old establishment of P. R.-des-Champs was exclusively devoted to the use of a lay community, in accordance with the original papal privilege. This community quickly became very celebrated, and soon numbered among its inmates some of the most distinguished scholars of that age, Antony Arnauld, Le Maistre, Antony and Louis Isaac le Maistre de Sacy, Nicole, Lancelot, Sericourt, and several others. Their rule of life was most austere, rising at 3 A.M., devoting many hours to prayer and spiritual reading and instruction, and a portion of the day to manual labor. One of their most important public services was the establishment of a school, for which they prepared the well-known educational books known under the name of Port Royal, the Greek and Latin Grammars, Geometry, Art of Thinking, &c. This school was for a time transferred to Paris, a portion of the nuns being sent back to P. R.-des-Champs; but eventually it was established at an out-farm of the latter place, called Les Granges.

P. R., however, is even more known in history through its relations with the Jansenist controversy. The nature and origin of these relations have been explained in the article *JANSEN* (q. v.). It only remains to relate the later fortunes of P. R. and its members, in so far as they were affected by the proceedings taken in consequence by the authorities, whether civil or ecclesiastical. The nuns of P. R. having refused to subscribe the formulary condemning the Five Propositions, a royal order was issued in 1660 for the suppression of the school, and the removal of the boarders of P. R.-des-champs; and at length the abbess, and several of the nuns, were arrested, and confined as prisoners in other monasteries. After the 'Peace of Clement IX.' they were permitted to return; but the two communities, P. R.-des-Champs and P. R.-de-Paris, were placed under separate government. This led to many disputes, and to a perpetuation in P. R.-des-Champs of the Jansenistic spirit and the Jansenistic opinions; and when the final steps for the repression of that party were taken about 1707, a formal bull was issued by Pope Clement XI. for the suppression of that convent, and the transfer of its property to P. R.-de-Paris.

The nuns, accordingly, were finally dispersed and distributed over convents of different orders throughout France. The property of the convent and church were transferred to the Paris house, and all the buildings of P. R.-des-Champs were levelled to the ground, by order of the king. Most of the eminent names connected with P. R. are under separate heads.

PORT SAID. See SUEZ CANAL.

PORT WINE (i. e., *Porto* or *Oporto Wine*), a species of red wine, hot and heady, which is produced chiefly in a mountainous district of Portugal, called Cima de Douro, and exported from Oporto and Lisbon. The vine from which this wine is produced is generally planted on craggy slopes with a southern exposure. The grapes are gathered from the commencement of September to the middle of October. The cultivation and gathering of the grapes for port wine employ annually 10,000 cultivators and 20,000 gatherers. The wine, when pure and unadulterated (which is very seldom the case), does not acquire its full strength and flavor till it has stood for some years, but care must likewise be taken that it is not allowed to become too old. The color of new port wine varies from pale rose to deep red, and changes with age, becoming a deep tawny brown, which is permanent. By far the greater portion of the wine made is mixed with spirit even during the time of fermentation, in order to give the new wine the ripeness and strength which exporters require, and which the wine does not naturally attain till it has stood for some time; the proper color is also given by an ingredient known as *jeropiga*, which is a preparation of elder-berries, molasses, raisin-juice, and spirit. It is an excess of this *jeropiga* in the inferior sorts of port which communicates to them the medicated odor so frequently noticed. The extreme 'headiness' of port is chiefly due to the liberal admixture with spirit, and this is the case with all the sorts generally exported. From the time when port came into demand (about 1700, though it was known in England for a considerable time before this) down to 1826, its export was a monopoly in the hands of the English merchants, and the amount of wine produced increased, with tolerable steadiness, year after year till 1836, when it reached 38,459 pipes, valued at £1,122,500.

The ultimate effect of this monopoly was to increase the price of port wine in England, and at the same time so to deteriorate its quality, that in course of time it became of less demand, and was gradually, to some extent, supplanted by Southern French and other wines. Since 1836 it has fluctuated, being sometimes more and sometimes less than this figure; in 1850 the exportation reached 37,487 pipes. Between 1876 and 1880 the exports to Great Britain ranged from 4,000,000 gallons to 3,000,000, and the value from £900,000 to £1,300,000.

PORTADOWN (Ir. *Port-na-Doon*, Port of the Fort), a market and manufacturing town of the county of Armagh, Ulster, Ireland, on the Bann, 11 miles north-east of Armagh by railway. It was formerly the seat of the McCanns, a clan tributary to the O'Neil, and formed part of the territory 'settled' by James I., and afterwards by Charles I. It is a place of considerable trade in corn, flax, and other agricultural produce, and is the seat of an extensive manufacture of linen yarns and linen. Communicating by canal with the sea at Newry, and by railway with Belfast, it has also a considerable import trade. The population in 1871 was 6785, of whom 8147 were Protestant Episcopalians, 1932 Roman Catholics, 857 Presbyterians, 715 Methodists. At the census of 1881 it had increased to 7850. P. is connected by the Ulster Railway with Armagh, Dungannon, and with several north-west counties.

PO'RTAL, the recess of a large doorway, such as the entrance to a church. See PORCH.

PORTAMENTO (Ital. *portare*, to carry), a musical term used for the sustaining of the voice, and passing from one note to another.

PORTARLINGTON, a market town and parliamentary borough, partly in the King's County, partly in the Queen's County, Leinster, Ireland, on the Barrow, 44 miles west-south-west from Dublin, with which it communicates by the Great Southern and Western Railway. Pop. in 1871, 2424, of whom 1688 were Roman Catholics, and 673 Protestant Episcopalians; (1881) 2426. P. was anciently called Coolteodra; but being granted by Charles II. to the Earl of Arlington, was called by his name. By him it was sold to Sir Patrick Traill; and on the attainder of Sir Patrick, was granted by William III. to General de Rouvigny, who planted in it a colony of French and Flemish Protestants, many of whose descendants still remain. It is now the property of the family of Dawson, Earls of Portarlington. It returns one member to parliament. The town is well built, and provided with two national, two endowed, and also private schools of considerable reputation, at one of which the late Duke of Wellington and his brother Lord Wellesley received part of their education. The rateable value of property is £4339.

PORTCULLIS (Fr. *porte*, gate, and *coulisse*, from *couler*, to flow), a frame of wood strengthened with iron in the form of a grating, and sliding in vertical grooves in the jambs of the entrance gate of a fortified place, in order to defend the gate in case of assault. The vertical bars were pointed with iron below, and struck on the ground, when the grating was dropped, so as to injure whatever it fell upon. In Heraldry, the portcullis is repre-

Fig. 1.

Fig. 2.

sented with rings at its uppermost angles, from which chains depended on either side. It was a badge of the Beaufort family, and borne in virtue of their Beaufort descent by the Tudor sovereigns. Portcullis is the title of a pursuivant in the English College of Arms, whose office was instituted by Henry VII.

PORTE, Sublime Porte, or Ottoman Porte, the name given to the Turkish government. The origin of this name is to be referred to the ancient oriental custom of making the gates of cities and of king's palaces places of assembly in connection with the affairs of government and of the administration of justice. In the Byzantine empire this custom was adopted, and the term was transferred from the high gate of the imperial palace to the government whose authority was there exercised. The Turks found the term in common use among the Byzantines some time previous to their establishment at Constantinople, and adopted it on the organization of their empire. The use among European nations, of the French term *Sublime Porte* ('Lofty Gate') is accounted for by the fact that French is the language of European diplomacy.

PORTER, DAVID D., Admiral of the American navy, son of Commodore David Porter who commanded the *Essex* frigate in the war of 1812, was born in Philadelphia in June 1813, entered the navy as midshipman in 1829, was employed from 1836 to 1841 in the survey of the coast of the United States; and employed four years on the Mediterranean and Brazil stations; in 1845, transferred to the National Observatory at Washington; again to the coast-survey; and from 1849 to 1853, engaged in command of the California mail-steamers. At the commencement of the war of 1861, he was appointed commander of the steam sloop-of-war *Ponchatam*, and ordered to Pensacola; distinguished himself in the capture of New Orleans and of Vicksburg, and in other events of the war. At the termination of the war, he was appointed superintendent and president *ex officio* of the U. S. Naval Academy, Annapolis. He was made vice-admiral in 1866, and in 1870 he became admiral, a rank which carries with it the command of the whole U. S. navy, subject only to the president.

PORTER, a kind of malt liquor which came into use in London in 1722. According to Leigh, 'the malt liquors previously in use were ale, beer, and twopenny, and it was customary to call for a pint or tankard of half-and-half—i. e., half of ale and half of beer, half of ale and half of twopenny, or half of beer and half of twopenny. In the course of time it also became the practice to ask for a pint or tankard of three-thirds [or, as it became corrupted, *three thirds*], meaning a third each of ale, beer, and twopenny; and thus the publican was obliged to go to three casks for a single pint of liquor. To avoid this trouble and waste, a brewer of the name of Harwood conceived the idea of making a liquor which should partake of the united flavors of ale, beer, and twopenny. He did so, and succeeded, calling it entire, or entire butt beer, meaning that it was drawn entirely from one cask or butt; and being a hearty nourishing liquor, it was very suitable for porters and other working people. Hence it obtained the name of Porter, and was first retailed at the Blue Last, Curtain Road, Shoreditch.' The chief characteristics of porter are its dark-brown color, peculiar bitter flavor, and agreeable freshness in drinking. Until within the last twenty years it was generally brewed with malt roasted until slightly brown; now, however, under the improved system of brewing, pale malt, with the addition of some highly roasted, for the sake of color only, is used. Enormous quantities are brewed by the London brewers. A kind much stronger than ordinary porter is also extensively brewed in London, Dublin, and elsewhere, under the name of *stout*. The name porter is now seldom used in England, beer being the general designation.

PORTFIRE is a sort of slow match for firing guns. It consists of a paper tube from 16 to 20 inches in length, filled with a composition thus proportioned—saltpetre 666 parts, sulphur 222 parts, mealed gunpowder 112 parts. The composition is rammed with force into the paper barrel, and then, when ignited, it burns for a considerable period. As a substitute, may be employed soft brown paper dipped in a solution of two ounces of nitre to a gallon of water, dried, and rolled up to the size of a common portfire. Another portfire consists of a rod cut square, of lime, birch, or poplar, boiled for six hours in a solution formed by dissolving one pound of nitre of lead in one quart of water. The rod is subsequently boiled in spirits of turpentine. When thoroughly dried, one yard will burn three hours.

PORTHOLES are embrasures or openings in the side of a ship of war to enable the guns to be ranged in battery. The portholes are ordinarily square, of size sufficient to enable the guns to be pointed at a considerable angle. In stormy weather the ports are closed, the guns being run in. When the guns are run out, and no fighting is anticipated, half-ports are employed to keep the water out. There is a row of ports for each gun-deck, and by these rows the rating of the vessel is described as a three-decker, two-decker, &c. Within the port, rings are fixed through which the ropes are passed for working the heavy guns.

PORTICI (formerly *Portico*), a town of Southern Italy, is situated on the slope of Vesuvius, near Herculaneum, 4 miles southeast from Naples, with 11,288 inhabitants. Its environs are delightful, and are dotted all over the country with houses. There is a royal palace built by Charles III., but it is crossed by the high road, which divides it in two. Facing the palace is a fortress rising out of the sea, and there is a small harbor called the Granatello.

PORTICO, a covered space with a roof supported by columns. It is usually attached to an important building, but sometimes detached, as a shady walk. A portico is called tetrastyle, hexastyle, octostyle, and decastyle, according as it has four, six, eight or ten columns in front.

PORTION, though not a legal term, is often used in the law of intestacy and legacies, and means a sum of money given to a child in discharge of the obligation incumbent on a parent; and from the circumstance of its being often given on marriage it is called a marriage-portion. By the law of England and Ireland, therein differing from the law of Scotland, a parent is not bound at common law to give any portion to his children. But he often does so by will; and, in the event of his dying intestate, the law does so for him. When a testator by will leaves a legacy to a daughter, child, or person, towards whom he stands *in loco parentis* and afterwards in his lifetime gives the child a like sum of money or even a less sum as a portion on marriage, such portion is *prima facie* presumed to be in satisfaction, or an ademption of the legacy, unless there is something in the will or settlement to rebut that presumption. But in Scotland there is no such presumption, unless the father was liable by contract to give the portion. See **TOCHER**.

PORTIONERS, in the Law of Scotland, mean two or more females who succeed jointly to heritable estate in default of heirs male, corresponding to Coparceners in England. See **HEIRS-PORTIONERS**. The holder of part of a fief was also called a portioner.

PORTLAND, a seaport of Maine, U.S., on an arm of Casco Bay, 105 miles north-east of Boston. It is situated on a peninsula three miles long by three-fourths of a mile broad, with broad shaded streets, and handsome public and private edifices, including a Court and Custom-house, a city hall, and Athenæum. There are near a score of newspapers, several of which are daily. The harbor of P. is large, deep, and well sheltered, and is the winter station of the Canadian steamers. It is defended by two forts. There are five railways, engine manufactories, sugar refineries, and a large coasting trade. P., first named Falmouth, was settled by an English colony in 1632, and was three times burned in the wars with the French and Indians. In 1866, a fire destroyed \$10,000,000 worth of property. Pop. (1870) 31,413; (1880) 33,810.

PORTLAND, the largest city of Oregon, U.S., 50 miles north of Salem, the capital of the state, is on a tributary of the Columbia River. It is the terminus of the Oregon Central Railway, has rapidly growing trade and thriving foundries, planing mills, and breweries. Pop. (1870) 8293; (1880) 17,698.

PORTLAND BEDS, a division of the Upper Oolites (q. v.), occurring between the Purbeck Beds and the Kimmeridge Clay, and so named because the rocks of the group form the promontory of the Isle of Portland. They consist of beds of hard oolitic limestone and freestone, interstratified with clays, and resting on light-colored sands, which contain marine fossils. The corals found in the sands are often converted into flints, the original structure being beautifully preserved in the hard silex. The beds

may be traced from the Isle of Portland, capping the oolitic hills as far as Oxfordshire. The fossils are chiefly mollusca and fish, with a few reptiles.

PORTLAND CEMENT. See **CEMENT**.

PORTLAND ISLE, a rocky peninsula projecting into the English Channel from the shore of Dorsetshire, 17 miles west-south-west of St. Alban's Head. Its appearance suggests the shape of a *beak*, and it is therefore called also the *Bill of Portland*. It is 9 miles in circumference, is composed of oolitic limestone, and slopes southward, with an even surface from the height of 490 feet to that of 30 feet above sea-level. Its sides are extremely rugged, and are worn into fantastic caverns by the furious action of the waves. The peninsula is supposed to have been once an island, but for ages it has been connected with the mainland by *Chesil Bank*, an extraordinary ridge of loose shingle, which, after running north-west in a straight line close to the shore for about 10 miles, joins the mainland at Abbotsbury. South-west winds prevail on this part of the coast, and during their continuance the long ridge of Chesil Bank is lashed by a frightful sea, and is the scene of frequent shipwrecks. A long narrow inlet of the sea, called the *Fleet*, extends between Chesil Bank and the shore, and is the haunt of numerous wild-fowl. *Portland Castle*, in the north of the isle, is a ponderous building, erected by Henry VIII. as a protection for this part of the coast in 1520. The peninsula furnishes the famous Portland Stone (q. v.). Portland Breakwater, built of stones obtained on the island, partly described under the article **BREAKWATER** (q. v.), has provided a secure harbor for hundreds of the largest ships; in connection with it are also a naval station, harbor of refuge, and batteries. *Pennsylvania Castle*, in a most romantic district on the east coast, was built by John Penn, the grandson of the founder of Pennsylvania. *Rufus Castle*, or, as it is commonly called, *Bow and Arrow Castle*, also on the east coast, is now in ruin, and is generally said to have been built by William Rufus. On Portland Bill, the southern extremity of the island, are two lighthouses, one 130, and the other 197 feet above sea-level. Between the southern point and the *Shambles*, three miles to the south-east, a dangerous surf, well known as the *Race of Portland*, is raised by the rushing of the impetuous tides.

The convict prison, near the east coast, erected in 1848, consists of eight wings, besides the hospital, chapel, barracks, and cottages for the warders. It accommodates upwards of 1500 convicts, besides the officers, and is maintained at an annual cost of upwards of £50,000, or at the rate of £33 per prisoner. The inhabitants of the island long remained a peculiar people; intermarrying, and preserving, generation after generation, the many curious customs of their ancestors. The island itself is chiefly remarkable for its abundant supply of excellent spring water, for its building-stone, and for its breed of sheep, the flesh of which, well known as Portland mutton, is celebrated for its flavor. The pop. of the parish of P. amounted in 1871 to 9907; in 1881, to 10,046.

PORTLAND SAGO. See **ARUM**.

PORTLAND STONE. This celebrated building stone, of which many of the principal buildings of London, including St. Paul's Cathedral, Somerset House, and many of the churches are constructed, is the oolitic limestone of Dorsetshire, constituting geologically the *Portland and Purbeck Beds*. The quarries are chiefly located in the islands of Portland and Purbeck, and in the Vale of Wardour. The quantity raised is very large. During the heavier works at the Portland Breakwater 730,000 tons per annum were required for that structure alone, and about 30,000 to 40,000 tons are sent annually to London and other places. There are three different qualities of the stone in the same quarry: the uppermost contains numerous fossils, and is of a coarse grain; it is therefore used chiefly for rough work, such as foundations. It is called *Roach* by the quarrymen. The middle bed is much broken, and is called the *rubble* or *rubbly bed*, and is of little value; and the lower one is fine, white, and compact, and is called the *whit*, or *best bed*. This last is that which is used for fine building purposes. An analysis of this stone by Professor Daniell shows the following composition:

Silica.....	1.20
Carbonate of Lime.....	95.16
Carbonate of Magnesia.....	1.20
Iron and Alumina.....	0.50
Water and loss.....	1.94

Besides which ingredients, there is often a trace of bitumen present.

PORTLAND VASE. A beautiful cinerary urn, of transparent dark-blue glass, found about the middle of the 16th c. in a marble sarcophagus near Rome (see the article **GLASS**, where it is figured and described). It was at first deposited in the Barberini Palace at Rome (and hence often called the Barberini Vase); it then became (1770) the property, by purchase, of Sir William

Hamilton (q. v.), from whose possession it passed into that of the Duchess of Portland. In 1810 the Duke of Portland, one of the trustees of the British Museum, allowed it to be placed in that institution, retaining his right over it as his own property. In 1845 a miscreant named William Lloyd, apparently from an insane love of mischief or a diseased ambition for notoriety, dashed this valuable relic to pieces with a stone. Owing to the defective state of the law, only a slight punishment could be inflicted; but an act was immediately passed, making such an offence punishable with imprisonment for two years, and one, two, or three public or private whippings. The pieces of the fractured vase were carefully gathered up, and afterwards united in a very complete manner; and thus repaired; it still exists in the Museum, but is not shown to the public. A small number of copies of the Portland Vase were made many years ago by Mr. Wedgwood, and were sold at 25 guineas each.

PORTLAW, a small manufacturing town of the county of Waterford, Munster, Ireland, about 10 miles west-north-west of Waterford. P. has risen within the last 40 years from a small village into a town of great activity and of extensive manufactures, through the enterprise of a single family named Malcomson, by whom the cotton manufacture has been introduced with great success. The population in 1871 was 3774, considerably more than 3000 of whom were Roman Catholics, the remainder being principally Protestant Episcopalians. P. is admirably provided with schools and other institutions for the social and moral improvement of the population.

PO'RTO ALE'GRE, a town of Brazil, capital of the province of Rio Grande do Sul, stands at the north-west extremity of the Lake of Patos, by means of which it communicates with the sea. It was founded in 1743, is well built, and contains 20,000 inhabitants. It is provided with wharfs; and its trade, though by no means inconsiderable, has hardly shared to the full in the recent advancement of the prosperity of Brazil.

PORTOBE'LLO, a parliamentary burgh and watering-place, occupies a plain on the south bank of the Firth of Forth, in the county of Edinburgh, and three miles east of the city of that name by the North British Railway. A commodious new town-hall was recently built. This town is a favorite resort for sea-bathing and summer quarters during the season. A marine promenade, a mile in length, runs along the shore; and there is an elegant iron pier, 1250 feet long, with seats to accommodate 2000 persons, and a spacious saloon for the use of visitors. P. is also a manufacturing town, and its manufacturing establishments comprise potteries, and earthenware, bottle, brick, and paper works, &c. Pop. (1881) 6793; and, in summer, between 7000 and 8000. The town derives its name from the first house built here about the time of the seizure of the town of Puerto Bello, in the Isthmus of Panama, and called Portobello.

PORTO BELLO. See **PUERTO BELLO**.

PO'RTO FERRA'JO. See **ELBA**.

PORTO MAURI'ZIO, a seaport town of North Italy, capital of a province on the Gulf of Genoa, 53 miles directly south-west of Genoa city. Area of province, 467 sq. miles; pop. (1890) 132,218. The town stands on a high promontory, projecting boldly into the sea. The harbor, defended by a mole, is generally crowded with the picturesque coasting-vessels of the Mediterranean. There is an extensive trade in olive-oil and agricultural produce. Pop. 7000.

PO'RTO NO'VO, a town in the Madras Presidency of India, situated on the Coromandel coast, in lat. 11° 31' N., and long. 79° 51' E. Both the Danes and the Dutch had formerly a factory here. The place is celebrated for the battle fought here on 1st July 1781, when Sir Eyre Coote defeated Hyder Ali. The British force consisted of only 7878 men, including artillery; Hyder's army numbered over 60,000. Coote was retiring before Hyder. After leaving P. N., he had only advanced a few miles along the seashore, when he found his path intercepted by the enemy's batteries, the sea confining him on the right, and a range of sand-hills on the left. The British army made two assaults; in one, they carried the batteries; in the other, they took advantage of an opening in the sand-hills, which Hyder had neglected to guard, and came suddenly upon the enemy's flank. A schooner of war meantime standing in close, poured her broadsides of small guns into the enemy. Their rout was complete. P. N. is celebrated for its iron foundry, which of late years has supplied much of the material for the Madras railways. Pop. of P. N., called by the natives *Parangipetta*, about 7200.

PO'RTO RI'CO. See **PUERTO RICO**.

PORTREE. See **SKYE**.

PO'RTREEVE (from *port* and *reeve*, Saxon *gerefa*, a word of similar origin to the German *graf*, signifying a governor or chief magistrate), the principal magistrate in a maritime town. This

was the early name of the officer afterwards called mayor in London and elsewhere.

PORTSEA ISLAND, a small island on the south coast of Hampshire, has on its west side Portsmouth Harbor, on its south-east side Langston Harbor, on its east side Chichester Harbor, and is separated from the mainland on the north by a narrow channel, crossed by several bridges. It is four miles long, by from two to three miles broad, and contains the important towns of Portsea and Portsmouth (q. v.).

PORTSMOUTH, the chief naval arsenal of Great Britain, and an important seaport, market-town, and municipal and parliamentary borough, in the south of Hampshire, stands on the south-west shore of Portsea Island (q. v.), at the entrance to Portsmouth Harbor, and opposite the town of Gosport, with which it communicates by means of a steam-bridge. It is 74 miles south-west of London by the London and South-western Railway. Besides the parish of P., the limits of the municipal and parliamentary borough, which are co-extensive, include also the parish and town of Portsea, and the out-wards Landport and Southsea. Pop. of the borough (1871), 113,569; (1881) 127,933. P. is for the most part a mean-looking, dirty town; but has the most complete fortifications in Britain. These comprise, on the landward side, the outer line of the Portsmouth forts and the Hulse line; to seaward, the Spithead forts (q. v.). The bastioned ramparts, which formerly encircled both P. and Gosport, and were so imposing in appearance, have recently been removed as useless. Southsea, which is situated outside the walls skirting Southsea Common, is rapidly increasing and is now a fashionable watering-place. In the town proper, there are few objects of note. Pleasing views may be had from the ramparts and batteries, as the harbor, the roadstead of Spithead, and the Isle of Wight. Many improvements have been recently carried out in P., including improved drainage, and the opening of the Victoria Park in 1878. Among the few notable buildings may be mentioned the church of St. Thomas, which dates partly from the 12th c., and contains a ghastly cenotaph in memory of the murdered Duke of Buckingham (see *infra*). In front of the Garrison Chapel is buried the brave Sir Charles James Napier (q. v.), who died in this neighborhood in 1858.

The dockyard of P., in the district of Portsea, was till lately only 116 acres in extent; but vast works have recently been carried out, at a cost of £2,500,000, which have increased the area to a total of 293 acres. Of this immense naval establishment, the most noteworthy, if not the most recent, features are the mast and rope houses, hemp-stores, rigging-stores, sail-loft, and the dry docks, spacious enough to admit the largest vessels, and offering every facility for their speedy repair. The 12 docks vary from 22 to 36 feet deep, lined with solid masonry, and roofed over, and closed by lock-gates. Of the various building-slips, one of them, roofed and covered in, is so large that three or four vessels can be in process of construction under it at the same time. The Wood Mills contain a number of most ingenious block-making machines, the invention of Sir Isambard Brunel, in which rough timber, introduced at one end, is cut, squared, drilled, bored, and turned into the required shape. About 150,000 blocks are made here annually, and the machines require the attendance of no more than four men. In the smithy, anchors are forged by aid of a Nasmyth's hammer. The dockyard also contains the residences of the superintending officers, and a school of naval architecture.

Portsmouth Harbor, about 420 yards wide at its entrance, expands into a spacious basin, extending inland for about 4 miles, and having a breadth of 3 miles along its northern shore. Large war-vessels can enter and lie at anchor at all times of the tide. The outward entrance is defended by Monkton Fort and Southsea Castle. The position of this harbor is highly favorable. It is situated in the middle of the channel, close to the magnificent anchorage of Spithead, where 1000 ships of the line may ride without inconvenience, and is under shelter of the Isle of Wight, and opposite the French arsenal at Cherbourg.

The local trade of P. is supported by the dock-yard and the other public establishments of the town. Brewing is largely carried on. Coals, cattle, sheep, corn, and provisions are imported from our own coasts, and timber and wine from abroad. In 1880, 2021 vessels, of 201,110 tons, entered, and 2020, of 206,729 tons, cleared the port.

The importance of this port dates only from the reign of Henry VIII. Its defences were strengthened by Elizabeth, and afterwards in a more thorough manner by William III. Here, in a house that still remains in the High Street, and which was then an inn called the 'Spotted Dog,' the Duke of Buckingham (the 'Steenie' of King James) was assassinated by John Felton. On the 29th of August 1782, when its commander, Admiral Kempenfeldt, was writing in his cabin, the *Royal George* went down in the harbor, and nearly 1000 lives were lost.

PORTSMOUTH, a city and the only seaport of New Hampshire, U. S., is on the south bank of the Piscataqua River, three miles from the Atlantic, and 54 miles north-north-east of Boston; a well-built town, having 10 churches, athenæum, state arsenal, academy and public schools, 2 market-houses, almshouse, 5 banks, manufactories of cotton and hosiery, foundries, and breweries. There is a safe and deep harbor, a United States' navy-yard, having a balance-dock, 350 feet long, and two forts, McCleary and Constitution. Settled in 1623. Pop. (1870) 9211; (1880) 9698.

PORTSMOUTH, a city and port of Virginia, U. S., on the west bank of Elizabeth River, opposite Norfolk, and 8 miles from Hampton Roads. It has a court-house, scientific and military academy, 5 newspapers, 13 churches, tobacco-factories, &c., and connections with the southern railways. Its proximity to Fortress Monroe caused it to be held during the War of Secession, by the Federal forces. Pop. (1870) 10,492; (1880) 11,888.

PORTSMOUTH, a village of Ohio, U. S., on the north bank of the Ohio River, at the mouth of the Scioto, the terminus of the Scioto and Hocking Valley Railway, and Ohio and Erie Canal, 115 miles east-by-south from Cincinnati, and 90 south of Columbus. It has 14 churches, 2 iron foundries, 3 machine-shops, 2 distilleries, 6 banks, and 5 newspapers. Pop. (1870) 10,592; (1880) 11,314.

PORTUGAL, the most westerly kingdom of Europe, a part of the great Spanish peninsula, lies in 36° 55'—42° 8' N. lat., and 6° 15'—9° 30' W. long. Its greatest length from north to south is 368 miles, and its average breadth from east to west about 100 miles. The census of 1878 showed a population for continental P. of 4,348,551, and with the Azores and Madeira, 4,745,124. The table gives the area and pop. in 1875 of the seven old provinces, with the corresponding official districts:

Provinces.	Districts.	Area in Sq. Miles.	Pop. 1875.
MINHO	Viana, Braga, Porto.	2810	973,332
TRAS OS MONTES.....	Braganza, Villa-Real.	4275	374,837
BEIRA ALTA.....	Aveiro, Coimbra, Viseu.	4533	930,730
BEIRA BAIXA.....	Guarda, Castello-Branco.	4688	388,868
ESTREMADURA.....	Leiria, Santarem, Lisboa.	6907	853,876
ALEMTEJO.....	Portalegre, Evora, Beja.	9389	342,979
ALGARVE.....	Faro.	1868	192,916
Total,		34,470	4,057,538

Islands.—The Azores, 920 square miles; pop. (1875) 261,746. Madeira, &c., 330 square miles; pop. 121,753. The islands are officially reckoned as belonging to the home territories.

The colonial possessions of P. are, in *Africa*—Cape Verd Islands, 1630.02 square miles; pop. 76,003. Senegambia, 35,437.50 square miles; pop. 8500. Islands of San-Thome and Principe, off Guinea, 448.56 sq. m.; pop. 23,681. Ajuda, 12 sq. m.; pop. 700. Angola, Benguela, 200,602.50 square miles, pop. 2,000,000. Mozambique and dependencies, 283,500 square miles; pop. 300,000. In *Asia*—Goa, Salcete, 1440.6 square miles; pop. 474,234. Damao, Diu, 94.08 square miles; pop. 53,233. In the Indian Archipelago, 2877 sq. m.; pop. 250,000. Macao, 11.76 sq. m.; pop. 71,739. Total of colonies, 526,041.48 square miles; pop. 3,258,140.

Physical Aspect, &c.—P. must be regarded as essentially a littoral country, forming the Atlantic or western part of the Spanish peninsula, from which it is separated by political, rather than physical boundaries. Its mountains and rivers are, with few exceptions, mere western prolongations of those of Spain. The principal mountain ranges lie about half-way inland, leaving almost the whole of its 500 miles of coastline a flat sandy tract, with a few rocky headlands, and hence there are scarcely any harbors or places of safe anchorage, except at the embouchures of the larger

rivers. The highest range is the Serra de Estrella, which, passing from north-north-east to south-south-west, through Beira and Estremadura, terminates in the steep acclivities of Cintra and Cap la Rocca, near Lisbon. The principal chain, which is also known as the Serra da Junto, merges in a series of ridges, which cover a tract thirty miles in length, between the Tagus and the sea. Another mountain range named the Serra de Caldeirão and the Serra de Monchique, but constituting a mere continuation of the Spanish Sierra Morena, crosses the southern part of P. from east to west, and terminates in its most southern promontory of Cape St. Vincent.

These ranges, with the numerous mountain-spurs that intersect the northern districts in every direction, so thoroughly occupy the area of P., that there are only two or three plains of any extent in the whole country, and these are situated to the west of the Guadiana, in Alentejo, and in Beira and Estremadura, near the Tagus and Vouga. The valleys are very numerous, and by their great fruitfulness, present a striking contrast to the barren and rugged mountains by which they are enclosed. The principal rivers enter P. from Spain. Of these, the largest are the Guadiana, which, leaving Spain near Badajoz, forms in part the boundary between the southern provinces of the neighboring kingdom; while the Minho and Douro, flowing west, form a part of the boundary in the north and north-east. The Tagus, or Tejo, intersects P. from its northern frontier to the southern termination of the Estrella Mountains, where it enters the sea a little below Lisbon. The Mondego, the largest river belonging entirely to P. after receiving numerous affluents in its course, falls into the sea about midway between the Douro and the Tagus. The larger rivers, although obstructed at their mouth with dangerous bars, afford admirable means of internal navigation, together with the numerous lesser streams, and might through canals be connected into one great system of water-routes; but hitherto nothing has been done to improve these great natural advantages. Except a few mountain tarns, P. has no lakes. It has salt-marshes on the coast, near Setúbal in Estremadura, and Aveiro in Beira, whence large quantities of salt are annually obtained by evaporation. Mineral springs are abundant in many parts of the country, but hitherto they have been almost wholly neglected.

The vicinity to the western ocean tempers the climate of P., and exempts it from the dry heat by which Spain is visited. The great inequalities of the surface produce, however, great diversities of climate; for while snow falls abundantly on the mountains in the northern provinces, it is never seen in the lowlands of the southern districts, where spring begins with the new year, and harvest is over by midsummer. Rain falls abundantly, especially on the coast, from October to March, and, as a general rule, the climate is healthy in the elevated districts even of the southern provinces; but malaria and fever prevail in low flat lands and near the salt marshes. The mean annual temperature at Lisbon is 61° Fahr.

The natural products correspond to the diversity of the physical and climatic conditions, for while barley, oats, and wheat, maize, flax, and hemp, are grown in the more elevated tracts, rice is cultivated in the lowlands, the oak thrives in the northern, the chestnut in the central, and the cork, date, and American aloe in the southern parts, while every species of European, and various kinds of semi-tropical fruits and vegetables, are grown in different parts of the country. The soil is generally rich, but agriculture is everywhere neglected, and is scarcely made subservient to the wants of the population. The cultivation of the vine and that of the olive are almost the sole branches of industry; from the former is derived the rich red wine familiarly known to us as Port, from its being shipped at *O Porto*, 'the port.' The mineral products include gold, antimony, lead, copper, marble, slate, coal, iron, and salt, but of these the last is alone worked in sufficient quantity for exportation, and is in eager demand for the British market, on account of its superior hardness, which adapts it specially for the salting of meat for ships.

The finest cattle are reared in the north, the horses of Alemtejo and the sheep of Beira are most valued. Mules and asses are the principal beasts of burden. Goats and pigs are numerous, and are raised at a very low cost, in all the mountain districts. The rearing of bees and silk-worms is being pursued with somewhat increased energy of late years. Fish is abundant in all the rivers and on the coast. The tunny and anchovy fisheries of Algarve are of considerable importance.

Commerce, &c.—The commercial industry of the country falls very far below its physical capabilities, and Oporto and Lisbon are the only centers of manufacture and trade, the former of which has important silk and glove manufactories, and produces an inconsiderable quantity of linen, cotton, and wool fabrics, metal and earthenware goods, tobacco, cigars, leather, &c. But in the 19 years preceding 1870, the agricultural exports had doubled. In 1880, the mercantile marine of P. comprised 498 vessels, measuring 87,060 cubic metres. In 1879, 3221 foreign vessels entered, and 4657 cleared the ports of P.; of Portuguese sea-going vessels

(excluding coasters), 1021 entered, and 796 cleared. In 1880, 780 miles of railway were open, and 280 more in course of construction, principally in the environs of Lisbon, Oporto, Santarém, and Vigo; but the country is almost entirely without roads, the few which exist having been made only within the last thirty years, before which time the whole of the kingdom was in the same impassable condition in which the southern provinces still remain. The scarcity and inefficiency of bridges, and the total want of canals, render internal traffic almost impracticable, and, as a matter of course, put an impassable barrier in the way of the progress of civilization, and the growth of material prosperity.

The exports, which consist almost entirely of wine, fruits, oil, and cork, are chiefly sent to Great Britain and her colonies. In 1880 the exports from P. to England were valued at £3,762,504, the value of the total exports being about £7,000,000. Amongst these exports, the wine alone monopolized one-third of the total value. The Portuguese imports from the United Kingdom in 1880 had a value of £2,608,818; the value of all the exports being above £4,000,000.

The budget for 1881-82 gives the public revenue, derived from direct and indirect taxation and from the national domains, at £6,841,000; while the expenditure, including home and foreign debts, the charges of the state, public works, &c., amounts to £7,613,000. There has been no budget for the last 30 years without a deficit. The budget for the foreign possessions of P. gives for the same year the receipts at near £480,000, considerably exceeded by the expenditure. The national debt in 1876, including foreign loans, amounted to close on £78,000,000.

Army and Navy.—The actual strength of the army was, in 1881, rated at 1643 officers and 83,281 men. The colonial army has 447 officers and 8156 men. The navy consisted, in 1881, of 27 steam-vessels, carrying 139 guns, and 14 vessels without steam-power, with 89 guns. The principal naval depôts are at Lisbon and Oporto. P. has 55 fortresses, the greater number of which are mere fortified castles. Among the more important are Elvas, S. Juliãs Cascaes, Pinimbe, Almeida, and Valença. There are six orders of knighthood—viz., the Order of Christ, founded in 1319; St. Benedict of Avis; the Tower and Sword, founded in 1459, and re-organized in 1808; Our Lady of Villa Viçosa, established in 1819; and the order of St. John of Jerusalem, which was separated in 1802 from that of Malta. Besides these, there is one civil service order, founded in 1288.

Religion, Education.—P. belongs almost exclusively to the Church of Rome, and shows little toleration to other creeds. At Lisbon and Oporto, Protestant places of worship are, however, sanctioned by the government. P. is divided into three dioceses, which are presided over by the Cardinal Patriarch of Lisbon, the Archbishop of Braga, who is primate of the kingdom, and the Archbishop of Evora; and these, with the fourteen bishops, belong to the Grandee, or higher nobility. The number of clergy holding cures is given at 18,000. The monasteries have been dissolved since 1834, but convents for nuns still exist. P. stands below the other countries of Europe in regard to education; which is now superintended by a superior council, at the head of which is the Minister of the Interior. Public education is entirely free from the supervision and control of the church. Compulsory education was enacted in 1844, but is far from fully enforced. In 1874 there were in P. and its islands 2031 elementary schools, with 2212 male and 509 female teachers, and 113,000 pupils; there are 18 lycées, and 57 other secondary schools; polytechnic academies at Lisbon and Oporto; and clerical, medical, naval, and military training-schools. The one university at Coimbra, one of the oldest in Europe, has five faculties, 52 professors, and about 1000 students. Lisbon has a learned society (the Academy of Sciences), and a public library of 300,000 volumes.

Law, Government, &c.—The administration of the law is effected by means of 111 courts of justice, 6 of which are located at Lisbon, where also the high court of appeal holds its sittings. The courts are public, and in some cases trial by jury is adopted. Excepting in regard to suits referring to trade, law is still administered in accordance with the Alfonsine code of the 15th c. and the Código Filippino, or code of Philip IV. of Spain.

P. is a constitutional monarchy, the crown being hereditary alike in the female and male lines. The houses of representatives are called *Cortes*, and consist of the *Camaras dos Pares*, and the *Camaras dos Deputados*, the former composed of grandees, chosen for life by the sovereign, and the latter of 149 members, elected by voters. The monarch is assisted by a cabinet of six ministers of state, and a council composed of members chosen for life. He bears the title of King of Portugal and of Algarve 'on both sides of the ocean.' The heir-apparent bears the title of Prince of Beira. The winter residence of the king and court is the Palace dos Necessidades at Lisbon, which at other seasons is exchanged for the palaces at Mafra, Queluz, Bemfica, and Ramalhão. The nobility is divided into *Titulados* and *Fidalgos*, and these, with the upper officials, higher clergy, &c., constitute one-eighth of the

whole population. Very many of the Fidalgos having been reduced to the condition of paupers, subsisting on charity, a law was passed in 1844, partly abolishing hereditary aristocracy, it being made dependent on the possession of an annual income of £500, together with an academical degree. The members of the second chamber are chosen directly by all citizens having an income of £23. The deputies must have at least £89 per annum; but graduates of any of the learned professions need no property qualification. Lisbon (q. v.), the capital, is the center of the small amount of literary, artistic, and manufacturing activity in P. Besides Oporto (q. v.) and the capital, there is no city whose population exceeds 20,000, and only 11 which have more than 10,000 inhabitants.

Race.—The Portuguese are a mixed race. In Algarve and Alentejo, the Arabic element is still very perceptible, and the people of those provinces have dark-brown skins, and tall, slim, but lithe and active figures; while the natives of the more northern districts, with lighter skins, have less regular features, small eyes, and short, thick-set figures. Although the Portuguese may very probably be regarded as the remains of the original population of the peninsula, they differ essentially from their Spanish brethren, whom they now regard with inveterate hatred and jealousy on account of their attempts a few centuries ago to annihilate the independence of Portugal. They indulge in interminable verbosity, ceremonious flattery, and servile politeness, and they are inclined to extravagance and display. They are, however, intensely patriotic, brave, persevering, enterprising, hospitable, cheerful, and ready to oblige. As a people, they are dirty and slovenly; few persons among them possess any great degree of mental culture, and the lower orders are even unable to read or write, and hence the grossest superstition and bigotry prevail in every class of the population.

History of Portugal.—The earliest notice which we have of the western portions of the Spanish peninsula, is derived from the Romans, who followed the Carthaginians as conquerors of the territories of the ancient Iberians and western Celts. Under Augustus, the peninsula was divided into three provinces, governed by prætors, of which the western province of Lusitania comprised the greater part of the present kingdom of P., besides portions of Leon and Spanish Estremadura. When the Romans withdrew from the peninsula, which was rapidly overrun by Visigoths from the north, and at a later period by Saracens from the south, Lusitania was overwhelmed in one common ruin with Iberia or ancient Spain. About the middle of the 11th c., it fell under the sway of Ferdinand I. of Castile.

In 1095, Henry of Burgundy, who had married a natural daughter of Alfonso VI., king of Castile, the successor of Ferdinand, received from that monarch the government of Portugal from the Minho to the Tagus, as a dependent fief. It is maintained, however, by Portuguese authorities, that even from this time the country was independent. His son, Alfonso I., gained signal advantages over the Arabs, and, by his gallantry and prudence, secured the affections of the people. After the great victory which he gained over the Moslems, in the plain of Ourique, in Alentejo, in 1139, his soldiers proclaimed him king. His successes on this occasion inflicted a serious check on the advance of the Infidels, and in recompense for the services which he had thus conferred on Christendom, the pope confirmed his title, which had been unanimously ratified by the Cortes of Lamego. The Burgundian House, which continued in possession of the throne for 400 years, gave to P. some of its noblest and best kings. The immediate successors of Alfonso I. were engaged in many severe struggles with the clergy and nobles, who were always ready to combine against the sovereign; but although often baffled in their attempts to uphold the independence of the crown, the dignity of the kingdom was, on the whole, well maintained by the representatives of this family, who are, moreover, distinguished as the promoters and upholders of the maritime glory of Portugal. Dinis (Dionysius), who succeeded Alfonso III. in 1279, must be regarded as the founder of Portuguese commerce and mercantile enterprise. This king, moreover, encouraged the industrial arts, and protected learning, in furtherance of which he founded, in 1284, a university at Lisbon, which was transferred, in 1308, to Coimbra. Dinis was succeeded in 1325 by his son, Alfonso, surnamed the Brave, whose reign was almost wholly occupied in wars with the Castilians and the Moslems. With Alfonso's grandson, Ferdinand I., the legitimate branch of the Burgundian House became extinct in 1385.

After some disturbances, his illegitimate brother, Joam (John), was recognized by the Cortes as king in 1385. His reign was eventful, not merely on account of the internal reforms which he introduced into the state, and of his steady maintenance of the prerogatives of the crown, but chiefly as being associated with the commencement of those vast and important geographical discoveries and commercial enterprises, to which P. owed the position she occupied during that and the succeeding age as the greatest maritime power of Europe. To Joam's son, Enrique (Henry)

the Navigator, is due the merit of having organized various voyages of discovery, and inaugurated a regular system of colonization, which, during the reign of Joam II. (who ascended the throne in 1481), culminated in the successive acquisition by P. of the Azores, Madeira, Cape de Verde, and other islands; in the doubling of the Cape of Good Hope under Bartholomeo Diaz; and, as the result of the latter, in the successful achievement of the passage by sea to India, which was effected, in 1497, under the command of Vasco de Gama, in the reign of Joam's successor, Manoel. The discovery of Brazil, and the settlements made there and on the western coast of India, increased the maritime power and fame of P., which were further extended under Manoel's son, Joam III., who ascended the throne in 1521. At this period, P. ranked as one of the most powerful monarchies in Europe, and Lisbon as one of its most important commercial cities. Sudden as this course of prosperity had been, its decline was almost more abrupt, and may in a great measure be referred to the influence of the priests, for the introduction into P. of the Inquisition in 1536, led to the expulsion of the numerous wealthy and industrious Jews, on whose able financial management the commercial interests of the Portuguese were largely dependent, and gave rise to an amount of social tyranny and oppression, both in the colonies and at home, which, coupled with a bad system of government, depressed the energy and crippled the resources of the nation.

The influence of the Jesuits under the minority of Joam's grandson, Sebastian, and their evil counsels in urging the young king to enter upon a fatal expedition to Africa against the Infidels, led to still further miseries. The defeat of the Portuguese, and the capture and death of their young king at the battle of Alcazar in 1578, and the extinction of the old Burgundian line in 1580, after the brief reign of Sebastian's uncle, Enrique, plunged the country into difficulties and misfortunes of every kind, which lost none of their weight, although they changed in character. After a struggle for the throne between many eager candidates, none of whom found favor with the nation at large, who persisted in cherishing the delusive hope that Sebastian was still alive, and would return from the hands of his Infidel captors, Philip II. of Spain succeeded in securing to himself the crown of P., and annexing the Portuguese kingdom to the Spanish monarchy. This event proved disastrous in the extreme to P., for, besides bringing the country to the brink of ruin, by mal-administration and misappropriation of its resources, it involved it in all the ruinous wars of Spain in the Low Countries and in Germany, a great part of the expenses of which it was made to bear; while the Dutch, in retaliation for Spanish aggressions at home, attacked the Portuguese settlements in Brazil, and almost completely deprived them of their possessions in the Indian Archipelago. The insolence of Philip IV.'s minister, Olivarez, brought matters to a crisis; and in 1640, after a forced union of 160 years, P. was freed, by a bold and successful conspiracy of the nobles, from all connection with Spain, and the Duke de Braganza, a descendant of the old royal family, placed on the throne, under the title of Joam IV. The war with Spain, which was the natural result of this act, terminated in 1668, when, by the treaty of Lisbon, the independence of P. was formally recognized by the Spanish government.

For the next hundred years, P. vegetated in a state of inglorious apathy. Her ancient glory had departed never to return, the nation was steeped in ignorance and bigotry, and from having been one of the greatest maritime powers of Europe, the Portuguese were content with becoming a commercial dependant, rather than ally, of Great Britain. Under the reign of Joseph I., who died in 1777, the genius and resolution of the minister, Pombal (q. v.), infused temporary vigor into the administration, and checked for a time the downward tendency of the national credit. Pombal's efforts to rouse the people from their sloth, and infuse vigor into the government, were frustrated by the accession of Joseph's daughter, Maria, who, with her uncle-husband, Pedro III., allowed things to fall back into their old channels. The mental alienation of Maria led, in 1789, to the nomination of a regency under her eldest son, Joam. This prince, who showed considerable capacity in early life, finding that he could not maintain even a shadow of independence on the outbreak of the war between Spain and France, threw himself wholly on the protection of England; and finally, when he learned that Napoleon had determined on the destruction of his dynasty, left P. in 1807, accompanied by all his family, and transferred the seat of his government to Rio Janeiro, the capital of Brazil. This act was immediately followed, on the part of the French, by the occupation and annexation of P.—a measure which gave rise to the Peninsular War. The victory of Vimeira, gained by the combined English and Portuguese army in 1808, freed the land from its French assailants; and in 1810, on the death of Queen Maria, the regent succeeded to the joint crowns of P. and Brazil. The continued residence of the new king, Joam VI., at Rio Janeiro, gave occasion to abuses and discontent, which resulted, in 1820, in the

outbreak of a revolution at Lisbon, and the proclamation of a constitutional form of government in the place of the pre-existing absolutism.

After a period of great national excitement and political disturbance, the differences between the sovereign and people were so far adjusted, that Joam agreed to and signed the constitution of P., and ratified the independence of Brazil, which was to be governed by his son, Dom Pedro, while he himself retained only the title of emperor. On the death of Joam in 1826, Pedro IV., after organizing the government of P. on the model of the French charter, renounced the Portuguese crown in favor of his daughter, Doña Maria da Gloria, on condition of her marriage with her uncle, Dom Miguel. The latter, who, during the lifetime of Joam, had availed himself of every opportunity to thwart the more liberal policy of his father and brother, waited only for the embarkation of the English troops to break the oath which he had taken to maintain the constitution, and gathering round him all who were in favor of restoring the old order of things in P., he was through their aid declared king by the Cortes, which met in June 1828. A period of indescribable confusion, misrule, and anarchy followed. The nobles, monks, and rabble ruled the land; 13,000 Portuguese citizens went into exile, while double that number of persons, suspected of favoring the Constitutional party, were kept in confinement.—At length, in 1832, Dom Pedro was enabled, chiefly by means of a loan from Englishmen, to raise a fleet, and make a landing at Oporto. Admiral Napier, in the meanwhile, operated on the coast of Algarve successfully in favor of the young queen, whose cause, by these victories, and the support of an alliance with the great powers, finally proved victorious. Doña Maria made her entry into Lisbon in 1833; and in the following year Dom Miguel signed the Convention of Evora by which he renounced all pretensions to the throne, and agreed to quit Portugal. The death of Dom Pedro in the same year, after he had effected several important reforms, proved a heavy misfortune to P., which suffered severely from the mercenary rule of those who occupied places of trust about the person of the young queen. Her marriage, in 1835, with Augustus, Duke of Leuchtenberg, his death at the end of a few months, and her second marriage, in 1836, with Prince Ferdinand of Saxe-Coburg, were followed by grave political disturbances, which in course of time were aggravated by the personal avarice and want of good faith of those in whom the young queen placed her confidence.

A branch of the democrats, known as the Septembrists, from the month in which they made their first decisive stand against the government, loudly demanded the abrogation of the charter promulgated by Dom Pedro (and known as the *Carta de ley* de 1826), and the restoration of the constitution of 1820. This contest of the charters may be said to have continued through the entire reign of Doña Maria. The government was alternately in the hands of Septembrists and Chartists, towards both of whom the queen acted with a degree of duplicity that frustrated every effort at an adjustment of the national disorders. Insurrections and counter-insurrections were of frequent occurrence, the troops were not to be depended on in moments of emergency; guerrilla bands scoured the country at will, and openly defied the queen's authority. The Absolutists, or Miguelites, took advantage of the general disorder to produce a reaction in favor of the old church party. The financial embarrassments were complicated in the extreme; while the obstinacy of the nation in regard to the maintenance of the slave-trade, in defiance of treaties and pledges, brought them into temporary collision with Great Britain, the only ally on whom Doña Maria could rely. An armed intervention of the great powers in 1847 produced a partial abatement of the national disorders; and matters might have permanently improved, had not the queen's partiality for her unpopular ministers, Count Thomar and his brother Cabral, and her determination to leave the administration of affairs in their hands, exasperated the general discontent and distrust of the court, and led to the insurrection, which, without bloodshed, made the national idol, the Marquis de Saldanha, *de facto* military dictator of Portugal, and evoked a general expression of the popular wish for the queen's abdication. Saldanha's ministry, although begun under good auspices, soon manifested the same readiness to succumb to the views of the court which had characterized former ministries.

One Cortes was dissolved after another, and finally, in 1852, the government declared itself prepared to carry out necessary reforms without the concurrence of the Cortes, and to demand at a future period a bill of indemnity for its acts. At this crisis, the queen died suddenly, and her eldest son ascended the throne in 1853, as Pedro V., under the regency of the king-consort his father. The latter used his power discreetly; and by his judicious management, the financial disorders were partially adjusted. Upon the sudden death in 1861 of Pedro, his brother was proclaimed king as Luis I. He has steadily adhered to constitutional principles, and aims at the internal improvement of the country; and in spite of frequent ministerial crises, and continual financial difficulties, the resources of the country are developing. When

the insurrection of General Prim broke out in Spain, the Portuguese chambers declared unanimously against any proposals for an 'Iberian Union.'

PORTUGUESE LANGUAGE AND LITERATURE. The Portuguese, like every other branch of the Romance family of languages, has grown out of a local form of the *Lingua Romana Rustica*, which in course of time had ingrafted upon it many elements of Arabic from the Saracen invaders of the country, and numerous verbal and idiomatic characteristics of the Frankish and Celtic dialects, which were introduced with the Burgundian founders of the Portuguese monarchy. The earlier forms of Portuguese bore close affinity with the Galician, and although, in course of time, it presented strong resemblance to its sister language, the Castilian, in as far as both possessed numerous words of identical origin, it differed so widely from the latter in regard to grammatical structure, as almost to merit the designation of an original tongue. The antipathy existing between the Portuguese and Spaniards, and the consequent strenuous efforts of their best writers to keep their language distinct, and to resist the introduction of further Castilian elements, had the effect of making Portuguese still more dissimilar from the sister tongues of the peninsula, and the result is the production of a language differing from pure Spanish in having an excess of nasal sounds, and fewer gutturals, with a softening or lisping of the consonants, and a deepening of the vowels, which renders it the softest, but least harmonious, and the feeblest of all the Romance tongues.

The earliest specimens of genuine Portuguese belong to the beginning of the 13th c., and consist for the most part of collections or books of songs (*Cancioneiros*), which, both in regard to form and rhythm, resembled the troubadour or *minne* songs of the same period. Of these, the oldest is the *Cancioneiro del Rei Dom Diniz*, or Book of Songs, by King Diniz, who had long been regarded by the Portuguese as their earliest poet, but whose poems were supposed to be lost, till they were discovered, about forty years since, in MS. in the library of the Vatican, and published at Paris and Lisbon in 1847. In the 14th and 15th centuries, the court continued to be the center of poetry and art, as it had been under Diniz; but Castilian was in greater vogue than Portuguese, which was despised by the numerous royal poets, who emulated the example of Diniz, and composed love-songs and moral or didactic poems. Under the culture of these noble bards, the poetry of Portugal remained weak and effeminate, without acquiring even the tenderness and pathos which characterized the Spanish romances of that age. The poetry and literature of Portugal acquired new vigor with the growth of her maritime and commercial glory, and the *Cancioneiro Geral* (Lisb. 1516) of the poet Garcia de Resende, which gives a general summary and extracts of all the Portuguese poets of the latter half of the 15th, and beginning of the 16th c., affords evidence of this improvement, which is most strongly exemplified in the sentimental pastorals or romances, and the national eclogues of Bernardino Ribeiro and Sá de Miranda, whose eclogues and prose dramatic imitations of Plautus and Terence, mark the transition period between the mediæval lyrical and the later classical style.

These first attempts at the drama were followed by Antonio Ferreira, whose *Ines de Castro* is the oldest Portuguese tragedy. But the classical school, whose chief cultivators were the courtiers of Lisbon and the professors of Coimbra, found little favor among the people at large, for the discoveries and conquests of the nation in Asia, Africa, and America, excited an enthusiasm and self-consciousness in the people, which led them to crave for something more practical and natural than the stilted style of the classicists. At this crisis, when P. was at the zenith of her material prosperity, appeared her greatest poet, Camoens, who in his immortal epic, *Os Lusíadas*, which appeared in 1572, struck out a new path in the domain of epic poetry; while his numerous sonnets, 300 in number, his *Campos* or songs, his *Redondillas*, dramas, and other poetic productions, exhibit a versatility of genius and graceful tenderness which place him in the foremost rank of European poets.

With Camoens and his contemporary, Gil Vicente, the language and poetry of P. reached the culminating point of their development. During the dominion of Spain, the Portuguese so far lost all feeling of national independence and patriotism, that they at length renounced their native tongue, and adopted the language of their foreign rulers. With the restoration of political independence, under the sway of the Portuguese House of Braganza, a reaction took place; but the 17th and 18th centuries produced few Portuguese writers who attained more than an ephemeral and purely local reputation—bombast, or slavish imitation of Spanish and Italian writers, being the predominant characteristics of the Portuguese school of light literature. Some good historical writers belong, however, to this period, as Jacinto Freire de Andrade, whose life of Joao de Castro, Viceroy of India, still holds its place as the most perfect monument of classical prose; the great Indian missionary, the Jesuit Father Antonio Vieira,

who died 1699, and whose sermons and letters—of which a collection was published at Lisbon in 1748, and at Paris in 1838—are regarded by his countrymen as models of style and diction; F. X. da Mensees, the author of *O Portugal Restaurado* (1741), &c.

In the beginning of the present century, Portuguese poetry was partially redeemed from its previous low grade by two men, who, although they professed to observe a strictly classical style, possessed a delicacy of taste, and a genial creative power, which saved them from falling into the absurdities that had generally characterized the school in Portugal. The elder of these, F. M. do Nascimento, who died in exile at Paris in 1819, although specially noted as an elegant lyricist, deserves notice for his gracefully written miscellaneous papers; while Manoel de Bocage, his less cultivated rival and contemporary, must undoubtedly be regarded as the most original and truly national of the modern poets of Portugal. His sonnets rank as the finest in the language, and these, with his numerous idylls, epigrams, and occasional poems, composed in various styles and modes of versification, have had a host of imitators, among the best of whom are the dramatist J. B. Gomes, J. M. da Costa e Silva; the satirist, T. da Almeida; and the Brazilian, Antonio Caldas, distinguished for his sacred epics, and various imitations of Milton and Klopstock. The best of the recent Portuguese poets are M. de Albuquerque, A. de Castilho, and A. de Carvalho, and J. B. d'Almeida Garrett. The last-named, whose collected poetic and prose works appeared at Lisbon in 1840, was at once the most versatile and popular writer of his time in Portugal. In the departments of travels, geography, and history, P. has produced good writers from the earliest periods of its literary history; and in recent times, the works of B. Machado, J. Ferreira, and A. de Cajo, have well maintained the national reputation.—Portuguese literature is also cultivated in Brazil, and, of late years, with more success than in the parent country. The principal names in Brazilian poetry are, Gonçalves Diaz, Macedo Abreu, and Magalhães; in history, Varnhagen, author of the *Historia geral do Brasil* (1854), and P. da Silva, author of the *Brazilian Plutarch*; besides some divines, philosophers, and translators from the classics.

PORTULACEÆ, or PORTULACACEÆ, a natural order of exogenous plants, nearly allied to *Caryophyllaceæ*, from which it differs chiefly in the generally perigynous stamens, the calyx consisting of two sepals which are united at the base, and the capsule frequently opening transversely. The species are not very numerous; they are much diffused over the world, and are shrubby or herbaceous, generally succulent, mostly growing in dry places. The flowers are often large and beautiful, but ephemeral. The foliage is bland and insipid. Some species are used as salads and pot-herbs, of which the best known is Purslane (q. v.). The tuberous roots of *Claytonia tuberosa*, a Siberian plant, are used for food, as are those of the Mellico (*Mellica tuberosa* or *Ullucus tuberosus*), a Peruvian plant sometimes referred to this order. The genus *Calandrinia* furnishes some beautiful annuals.

POSCHAREVATZ. See **PASSAROWITZ.**

POSEI'DON. See **NEPTUNE.**

POSEN, a province of Prussia, bounded N. by Pomerania and East Prussia, E. by Poland, S. by Silesia, and W. by Brandenburg and Pomerania. Area, 11,150 square miles. Pop. at the close of 1880, 1,703,397. It is divided into the two governmental districts of Posen and Bromberg; and the principal towns are Posen, Bromberg, Lissa, Rawitsch, and Gnesen. The principal river is the Wartha, which traverses P. from east to west, and is navigable throughout the greater part of its course, as is also the smaller Netze. The country is almost everywhere level, and its surface extensively covered with bogs, ponds, and small lakes. The soil is on the whole fruitful, and the numerous swamps and forests which covered the land during its annexation to Poland, have of late years been converted into rich meadow and good arable land, where cattle of superior quality are raised, and good crops of wheat, barley, oats, and flax are procured. The forests are extensive and productive, and contribute largely to the exports of the province, of which, however, the most important articles are corn, wool, tallow, hides, wax, and honey. With the exception of coal, which is obtained from beds near the town of Wronki, P. has no mineral products. Good broad-cloth, linens, and lace are manufactured in many of the small country-towns.

Since the annexation of P. to Prussia, much has been done to supply the previous deficiency in regard to popular instruction; and there are now nine gymnasia, several normal and training schools, a seminary for priests, and upwards of 2000 burgher and national schools. The greater part of the population belongs to the Roman Catholic Church, which is under the spiritual jurisdiction of the Archbishop of P. and Gnesen, while 74,000 of the remainder are Jews. The inhabitants may still be said to be Poles, more than 800,000 persons employing Polish as their mother-tongue. P. formed an integral part of Poland till 1772, when, at the first partition of the Polish territory, the districts north of the Netze were given to Prussia. At the second and third partitions, which

were made 20 years later, the remainder was incorporated in the Prussian kingdom under the name of South Prussia. In 1807, P. was included in the duchy of Warsaw; but by the act of the Congress of Vienna, it was separated in 1815 from Poland, and re-assigned to Prussia under the title of the Grand Duchy of Posen. In 1848, the Poles, who had never amalgamated with their new German compatriots, took advantage of the general political excitement of that period to organize an open rebellion, which gave the Prussian government considerable trouble, and was not put down till much blood had been spilled on both sides. On the cessation of disturbances, the German citizens of the province demanded the incorporation of P. with these Prussian states which were members of the German Confederation, and the Berlin Chambers gave their approval of the proposed measure in 1850; but on the subsidence of revolutionary sentiment in Germany, the subject was dropped.

POSEN (Polish *Poznan*), the chief town of the province of Posen, and a Prussian fortress of the first rank, is situated on the low and sandy banks of the Wartha, nearly 150 miles east of Berlin. Pop. (1871) 56,374; (1880) 65,713—of whom not quite the half are Protestants and towards 10,000 are Jews. P., which ranks as one of the most ancient cities of Poland, became the seat of a Christian bishop in the 10th c. Till 1296 it was the seat of the Polish dukes; and it was a member of the Hanseatic League during the middle ages, when it was an important trading mart between Western Europe and the Slavonic lands bordering on Asia. At this time many German, English, and Scottish traders settled in P., which latterly fell into decay. It passed into the possession of Prussia in 1815. At the great fire of 1803, when many of the older parts of the town were destroyed, P. lost the most striking features of its semi-oriental style of architecture; but it still retains a certain picturesque character, from the number of its church towers and lofty houses. Among its 15 principal churches, the most noteworthy are the cathedral, a recently restored and elaborately ornamented building, and St. Stanislaus, a splendid specimen of Italian architecture. P., which has been strongly fortified since 1828, is encircled by six suburbs. It is the see of an archbishop, the seat of the provincial government, and has a fine town-hall, two gymnasia, a public library with 20,000 volumes, training-schools for teachers of both sexes, a school for midwives, a theater, &c. Recent restorations and improvements have rendered it one of the pleasantest-looking towns in Prussia, and it can now boast of many fine regularly built streets and squares, in which are situated the winter residences of many of the provincial Polish nobles. A considerable trade in wood, corn, wool, broad-cloth, and linen, is carried on here, principally by the Jews, and the annual fairs held in summer attract large crowds from all parts of the province. The chief manufactures of P. are cloth, leather, carriages, copper vats and other vessels used in distilling, and tobacco; while there are likewise several breweries, distilleries, and sugar-refineries.

POSES PLASTIQUES (Fr. 'statuesque attitudes'), equivalent to *Tableaux Vivants* (q. v.).

POSIL'IPO, a mountain on the north-west of Naples, close by the city, remarkable for the tunnel known as the Grotta di Posilipo, through which the road from Naples to Pozzuoli (anc. *Puteoli*) passes. The grotto is in some places 70 feet high, and 21 feet wide, and is 2244 feet long. It is very ancient. Seneca mentions it as the *Crypta Neapolitana*. Strabo assigns its construction to M. Cocceius Nerva, superintendent of aqueducts in the time of the Emperor Tiberius. Above the eastern archway of the grotto is the so-called 'Tomb of Virgil.' At the base of the hill of P. anciently stood the poet's villa, in which he composed the *Eclogues* and *Georgics*, if not also the *Æneid*. During the middle ages, the common people firmly believed the grotto to be the work of the poet, whom they regarded as a great magician.

PO'SITIVE PHILO'SOPHY. See **COMTE.**

POSITIVISM, the System of Thought and Life founded by Auguste Comte (q. v.) is defined by him as consisting essentially of a 'philosophy and a polity which can never be discovered; the former being the basis, and the latter the end, of one comprehensive system, in which our intellectual faculties and our social sympathies are brought into close correlation with each other.' He chose the word *Positive* on the ground of its indicating the *reality* and *constructive tendency* which he claimed for the doctrine in its theoretical aspect, while he anticipated that in the future the term would acquire a wider meaning by suggesting also similar ideas in the sphere of feeling and action. The two primary characters of P., the philosophy and the polity, were finally welded into a whole under the conception of a religion, which has for its creed the new synthesis established by the one, and for its practice the scheme of moral and social reorganization proposed by the other. We may best consider P. under these three aspects.

Positive Philosophy.—Comte's primary aim was to put an end

to the intellectual and social anarchy which had resulted from the destructive criticism and the revolutionary upheaval of the eighteenth century, by supplying an interpretation of phenomena which should organize our knowledge of the world, of man, of society, into a consistent whole. Such a universal synthesis must the new philosophy provide, to form a sure basis for a new art of life.

Historical analysis revealed to Comte, as a law of mental growth, the progress of all human conceptions through three distinct phases. The primitive stage he called the *theological*; the transition stage, the *metaphysical*; and the final stage, the *positive*. The meanings which he attaches to these words are most concisely explained by Stuart Mill's translation of them into volitional, abstract, experiential (see COMTE). The transition was effected by the gradual acceptance of the scientific method of induction from observation of phenomena as the only sound basis of explanation, all inquiry into causes other than phenomenal being finally given up as fruitless. Science, therefore, is the instrument capable of effecting the desired unity; and the problem of the positive philosophy is a three-fold one: (1) To bring all knowledge within the sphere of scientific investigation; (2) To extend scientific methods through the whole territory of each division; (3) To co-ordinate the results obtained from the separate sciences, so as to approach an expression of all our knowledge in terms of a single doctrine. All three parts of this problem Comte considered to be in a large degree solved by his *Classification of the Sciences*.

He observed that the several classes of conceptions advanced from the theological to the positive stage with different degrees of facility, and on inquiring into the law of progression, he found that the order of emancipation of the various sciences was determined by the degree of complexity and the consequent relations of dependence. A preliminary distinction was made between the abstract and the concrete sciences, the former treating separately of the general laws manifested by all the phenomena of any class, and the latter depending on these and treating of definite objects under the several aspects in which they may be viewed. The concrete sciences, Comte considered, did not yet admit of co-ordination, and he confined his classification to the abstract sciences, which he placed in the following series: 1. Mathematics; 2. Astronomy; 3. Physics; 4. Chemistry; 5. Biology; each of these drawing its data from the preceding science, and adding a new order of conceptions peculiar to itself. This series he found coincident with the sphere of knowledge then supposed to admit of scientific treatment. But there remained the phenomena of human character and society, forming a wide field of inquiry to which positive methods had never yet been applied. Certain tentative efforts had indeed been made to construct a so-called science of history—notably by Condorcet and St. Simon—but no one before Comte had formulated the principles on which such a task might be accomplished. By his discovery of the methods proper to a rational study of social phenomena, his dicta—that owing to the complexity of the conditions involved, the laws of such phenomena cannot be determined *a priori*, but must be inductively observed, and afterwards verified and co-ordinated by deductive application of the general laws of life; that the static condition of each historical period must be viewed in its totality, as determined by the interaction of the various classes of social factors; that intellectual evolution affords the true measure of social progress; by his enunciation of these and other doctrines, Sociology was created and established in the hierarchy as the last and crowning science of the series.

The whole realm of fact was now included in the domain of positive inquiry, and Comte next addressed himself to the task of rationalizing the separate departments of knowledge. In the earlier portion of this task, his mathematical aptitude insured him a large measure of success; while in biology he paved the way for further developments by his organization of the materials then available. His main services, however, in scientific co-ordination were in the department of sociology. Besides the formal constitution which he gave to the new science, his chief substantive contribution was his enunciation of the fundamental law of intellectual development, already referred to as the cardinal doctrine of the positive philosophy. The progress of thought, moreover, from theological to positive conceptions, was shown to be coincident with a progression in social action from an aggressive militarism, through a period of defensive attitude to the final régime of Industrialism. The two series of transitions are mutually dependent, our increasing knowledge of the conditions of our existence, and our systematic efforts to modify them, naturally reacting on each other.

The main problem of the positive philosophy, the unification of knowledge, was not yet ripe for its final solution in the days of Comte, but his classification of the sciences is regarded by his followers as affording an admirable framework for the theory of evolution advanced at a later date with the claim of supplying this want. Comte was fain to be content with the demonstration of a

subjective unity in the subservience of all the sciences to the needs of man.

Positive Polity.—On the basis of the philosophy he had thus established, Comte founded a scheme of individual and social conduct. The ethical portion he did not live to complete, but in his elaborate exposition of the art of social politics we have ample insight into his views on what he considered an integral part of his system. We have space here only for a bare outline.

The most complete life must be that which rests on the fullest knowledge. We naturally strive to improve those conditions of our existence which we can affect, in the direction indicated by the clearer light of a new synthesis. What, then, are the evils or imperfections of our lot which may be remedied by applying positive philosophy to life? Cosmical laws are wholly beyond our direct influence, and we can only to a limited extent affect the conditions of their action. But in the science of man we ourselves are the factors, and our efforts to modify our environment form the subjective aspect of what is, objectively considered, a law of social development.

Comte believed the first requisite of systematic action to be the recognition of a central intellectual and moral authority dissociated from practical politics, which he proposed to secure by organizing a *Spiritual Power*, consisting of philosophers, supported by the state. This class, exerting a purely moral control, yet supreme in all affairs of private and social life in virtue of its natural prestige, would have only an indirect influence on political action. The temporal power should be in the hands of capitalists, the captains of industry—chosen by their own order and naming their successors—who would feel a moral responsibility to the spiritual power, especially when the authority of the thinkers should be strengthened by the support of women and of the working classes, whose ready adherence to positive principles Comte firmly anticipated. Besides the corrective influence of each of these powers on the other, an efficient check on despotic control on the part of either is provided in the perfect freedom of opinion and expression allowed—a freedom the more valuable that it would rest on a system of scientific and moral education, which it would be one of the chief functions of the spiritual power to direct and enforce.

With the decline of militarism and the growth of industrialism, Comte foresaw that political action would in the future be mainly directed on the organization of labor for the benefit of society at large. No idleness would be permitted; all would be workers. The distinction between the capitalists and the workmen, the rich and the relatively poor, would remain; but the former would be taught to hold their wealth and power as in trust from society to be used for the benefit of all, while the latter would also come to regard themselves as performing public functions, serving society each in his place. These views are substantially similar to such more recent economic teaching as that of Carlyle and Ruskin in our own country.

In the sphere of morals, the main office of the spiritual power would be to strengthen the social tendencies of man at the expense of the personal, a process made possible by the development of the affections originally called forth in family life. In the sphere of intellect, it should regulate and concentrate the labors of its members, putting an end to the present 'dispersive speciality' of scientific aims, and determining the direction of all intellectual efforts by reference to social needs. In pursuance of the constructive principles of P., Comte applies these general doctrines to the immediate future, by propounding a scheme of concerted action for a great Western Republic, embracing the French, English, German, Italian, and Spanish nations—an organization imperfectly effected by the influence of Feudalism and Christianity.

Positivist Religion.—Such are the creed and the practice of P. But a religion is more than creed and practice; there must be a sentiment, an appeal to the heart, a satisfaction of the feelings. The conception of an object of love and reverence proposed by Comte to succeed the idea of a Deity (whose existence he considered it impossible either to affirm or deny), is that of *Humanity*, regarded as a collective unity, a *great being*, consisting of all the men and women past, present, and to come, whose lives have been, or shall be devoted to the well-being and progress of the race. This being, partly ideal yet wholly real, capable of being definitely conceived, and not beyond the reach of our services, would gather round it all our affections for our fellow-men; gratitude and reverence for those whose struggles and achievements in the past have made us what we are; love and sympathy for all around us who are striving after better things; hope and effort for the more perfect life of those yet unborn. Comte looked on the religion of humanity as fulfilling all the highest aims sought by the religions of the past, and especially as succeeding naturally to Christianity, the historical value of which he thoroughly appreciated as a transitional phase of religious development. The worship of humanity was to consist in prayer, taking the form of high resolve strengthened by effort after ideal communion with

the noble spirits among the dead; and in public commemorations, for the observance of which a calendar was suggested, associating each day of the year with some great name in the roll of mankind, and arranged so as to illustrate the course of human progress. The spiritual power would carry on the traditions of the priesthoods of former religions, preaching self-abnegation as the rule of life bringing the highest happiness, and offering no reward, save a place in the 'choir invisible' of the great and good, whose names are cherished in the hearts of those who follow them, and whose influence will live to the end of time.

P. is of too recent origin to be adequately treated except in an account of its genesis, and the above outline of the system has therefore been entirely confined to the works of its founder. In his lifetime, Comte attached to himself a body of disciples more remarkable for intellectual eminence than for numbers. The most prominent of these was the late M. Littré (q. v.), who afterwards edited his master's works, and established a review with the title of *La Philosophie Positive*. His discipleship, however, did not extend to the later developments of the system. Near the end of his life, Comte founded the Positivist Society, the present director of which is M. Pierre Laffitte. The organization has its headquarters in Paris, but it has extended to most other countries, and the number of adherents increases slowly but steadily. The *Revue Occidentale*, their organ in the press, is published quarterly in Paris. Among the best known of the English Positivists are Dr. Congreve, Mr. Frederic Harrison, Dr. Bridges, and Professor Beesly.

Among sympathetic critics of P. are many thinkers of eminence imbued with the positive spirit, and more or less indebted to the genius of Comte. Stuart Mill, in his work on *Auguste Comte and Positivism*, though taking an independent standpoint, speaks in terms of high appreciation not only of the leading doctrines of the positive philosophy, but also of the conception of humanity as a *Grand Être*, which is the keystone of the new religion. Many of the details of ritual and worship, however, were repugnant to him, as they have proved to many; and while exaggerating the importance of these, he makes an arbitrary separation between the earlier and the later portions of Comte's career. His book should be read along with Dr. Bridges' reply, entitled *The Unity of Comte's Life and Doctrines*. Mr. Herbert Spencer, though undoubtedly owing much to Comte, has been more careful to vindicate his independence than to acknowledge his obligation. His references to his great predecessor mostly concern their disagreements.

In two essays, one on *The Genesis of Science*, and the other on *The Classification of the Sciences*, he opposes Comte's views on these subjects—not to the satisfaction of other competent critics—and he has even thought it necessary to publish an article entitled *Reasons for dissenting from the Philosophy of M. Comte*. Mr. Spencer's exposition of the theory of evolution is regarded by Positivists as a valuable contribution to that scientific philosophy, the inauguration of which they claim for their master. G. H. Lewes, in the chapter on Comte in his *History of Philosophy*, calls him the greatest thinker of modern times, and declares himself an ardent adherent of the positive philosophy. For the religious aspects of P., however, Lewes's feeling is one of partial sympathy only. In 'George Eliot's' works, the influence of Comte's doctrines is evident, and she has devoted one of her poems to the interpretation of the positivist conception of immortality.

Among critics, wholly antagonistic to P. are naturally to be found the theologians and so-called metaphysicians, i. e., all whose explanations of phenomena either assume the action of supernatural beings, or are expressed in terms of abstractions such as *vital principle*, *inherent tendency*, *nature*. Such thinkers, generally profess little knowledge of scientific fact; but with these may be included many scientific specialists whose contracted view of the phenomenal world unfits them for general conceptions, and leaves them open to theological and metaphysical influences beyond the immediate sphere of their own specialty. The opposition of these classes follows from the refusal of P. to recognize the claims of such modes of thought to other than an historical importance.

POSITIVE PRINTING, in Photography. This term is used to designate that process by which impressions from a Negative (q. v.) are produced upon suitably prepared paper. The term, however, does not belong exclusively to positives produced on paper, and intended to be viewed by reflected light, since transparent positives for examination by transmitted light are produced on glass. The means by which this kind of positives is obtained are so exactly similar to the dry negative collodion process, that a detailed notice thereof is hardly necessary in the present article, which will be confined exclusively to the means of obtaining positive proofs on paper.

Regarding, then, the negative, not so much as the picture as the means of producing one, the first thing which presents itself for notice is the paper. This may be either German or French,

known in the markets under the respective names of Saxe and Rive. They are used in the simply salted condition, or more generally in the salted and albuminized state, the purpose of the albuminizing being to prevent the chemicals used in the process from sinking into the paper, whereby the delicate details of the negative would become defective on the surface. The process is briefly as follows: Float the paper on the salting bath from one to five minutes; drain for one minute; hang up to dry. Float the paper on the exciting bath from five to ten minutes, according to its strength; drain and hang up to dry. Expose in a pressure-frame under a negative. The necessary depth of impression, being obtained (a point only to be determined by experience), wash the print in common water. Some operators at this stage immerse the print in a bath containing one per cent. of ammonia for two or three minutes. This is by no means absolutely necessary; should it, however, be done, it should be afterwards washed in water for five or ten minutes; after which it is immersed in the toning bath from one to ten minutes, or until the desired tone be obtained; it is then washed in several changes of water, preparatory to immersion in the fixing bath. This last operation occupies from fifteen to thirty minutes, according to the strength of the fixing solution, and the depth to which the printing has been carried. The print is then copiously washed in many changes of water, and hung up to dry.

The baths referred to above are composed as follow: *Salting Bath*, water, 1 ounce; albumen, 4 ounces; good common salt, 48 grains. *Exciting Bath*, nitrate of silver, 240 grains; water, 4 ounces; glacial acetic acid, half a dram. *Toning Bath*, chloride of gold, 4 grains; water, 24 ounces; carbonate soda, 100 grains. *Fixing Bath*, hypo-sulphite of soda, 4 ounces; water, 1 pint.

Printing in carbon, lamp-black, or other impalpable powder, which doubts as to the stability of silver prints had long made a *desideratum*, has recently been brought to a considerable degree of perfection. It is based on the discovery by Mungo Ponton, that a mixture of gelatine and bichromate of potass is rendered insoluble by the action of light, and on the experiments of Poitevin, Fargier, and Blair. There are three typical processes—the *Autotype*, *Woodburytype*, and *Lichtdruck*. The *Autotype* consists in coating a sheet of prepared paper with a mixture of gelatine, bichromate of potass, and carbon, and when dry, exposing it under a negative. On removal from the printing frame, the pigment is moistened with water, and laid, prepared side down, on a support of glass, zinc, or shellac-coated paper, to which a gentle pressure makes it adhere. The paper is then removed, and the print developed by immersion in warm water, which dissolves the unaltered gelatine, but cannot touch the parts rendered insoluble by the light which has passed through the negative. The developed print is again transferred to paper, when the high lights are found to consist of those parts where the gelatine has been completely dissolved, the middle tints of the parts less soluble, and the shadows of the parts quite insoluble.—In the *Woodburytype*, a bichromated gelatine film, but without carbon is prepared, exposed, and developed in a somewhat similar way, but dried without being transferred to paper, the result being a sheet of gelatine with a picture in *relief*. This is laid on a plate of soft metal, and covered with a plate of steel, and the whole subjected to the action of a hydraulic press; by which the soft metal takes the impression of the gelatine film.

In printing from the plate so produced, an ink, consisting of carbon and gelatine, is poured on the center, the paper is laid on the ink, and the pressure of a suitable press applied, whereby the ink is squeezed into the shadows and half tones, and the high lights are left clean, the result being a really fine print. Glass may be used instead of paper, with very fine results.—*Lichtdruck* is a method of printing photographs in an ordinary lithographic press, with printer's ink, from gelatine films prepared on the same principle as the *Woodburytype*, except that the soluble gelatine is not washed away. The film is attached to a thick plate of glass fixed in the press and when sponged over, the soluble parts absorb water, and so are prevented from taking on ink, while the insoluble portions remain dry, and the ink adheres to them.

PO'SSÉ COMITA'TUS means the whole force of the county, consisting of knights and men above the age of 15, with constables, who attend the orders of the sheriff to assist in enforcing process or quelling riots. Justices of the peace can also, if apprehensive of an organized resistance, command the services of the posse comitatus, and it is the sheriff's duty to raise the necessary number of men. But practically, in modern times, constables and special constables are all the assistance given or required.

POSSE'SSION OF PROPERTY, in point of law, is the most intimate relation that can subsist between the owner and his property. Strictly speaking, the idea of property consists merely of a certain relation between a human being and a portion of external nature, whereby he appropriates to himself all the ordinary uses of which such external nature is capable. If it is land, he reaps the fruits, and excludes all other persons from interfering with

his operations; if it is a chattel, he keeps it under his exclusive control. Possession, therefore, is nothing but the legal result of the relation of property. Possession, though originally constituting the whole substance of property, has, as civilization advanced, become a separable part of it; and while the radical right is now the ownership, the possession is viewed as an incident of such ownership. It is now not only separable but saleable, and constitutes the foundation of the contract between landlord and tenant, whereby the owner, by way of a lease, sells for a limited period the exclusive use, otherwise called the possession.

So long, therefore, as an owner exists, he has, as a necessary consequence, the right, more or less immediately and directly, to the possession of property. When all record of ownership is lost, then the law permits a resort to first principles, and allows any person who has been in possession for a limited time to retain it, and so ultimately to acquire the ownership. If the possession is suddenly or wrongfully interfered with, the usual remedy, in England, to recover possession of real property, such as land or houses, is an action of ejectment; if the property is a chattel, it is an action of trover or detinue. But the possession may be recovered also by other modes. See also OWNERSHIP and LOST PROPERTY.

PO'SSET, a dietetic preparation, made by curdling milk with some acidulous liquor, such as wine, ale, or vinegar. White wine or sherry is usually preferred, but sometimes old ale is used. The milk is boiled; and whilst it is still on the fire, the acidulous matter is added; if sherry, about a wine-glassful and a half to the pint of new milk is the proportion; or twice the quantity if ale. A teaspoonful of vinegar or of lemon-juice is sometimes used instead; one or two tablespoonfuls of treacle are added, to sweeten. Taken at bedtime, it is used for colds and coughs.

POST-CAPTAIN, an obsolete title applied to captains in the royal navy: it has been disused for many years. See CAPTAIN.

POSTE RESTANTE (Fr., to remain at the post-office till called for), a usual mode of addressing letters to persons who are merely traveling in, or passing through a country in which they have no fixed residence. English travelers on the continent have very generally their letters so addressed to some town through which they expect to pass. The *poste restante* office is open at certain hours, and the letters are given out when called for, production of a card, passport, or other evidence of identity being sometimes required. Letters unclaimed for a certain time are opened, and either destroyed or returned to their writer. There is a *poste restante* office in London, under stringent regulations as to the conditions on which letters are given out. If the applicant for a letter be a British subject, or subject of a state not issuing passports, he must state the place from which he expects letters, and he, or the messenger who applies for him, must be provided with some proof of identity. If he be the subject of a country which issues passports, his passport must be produced.

In the provincial post-offices of Great Britain, commercial travelers, tourists, and persons without a settled residence, may have their letters addressed *poste restante*, and they are kept at the post-office till called for; but residents are not allowed to have their letters so addressed, and the post-office authorities have orders to deliver them. In the British post-office, letters addressed *poste restante* are kept one month, and then returned to the writer through the dead-letter office.

PO'STERN, in Fortification, is a small doorway communicating usually through the flank of a bastion between the fort and the ditch. Its object is to afford unseen egress to troops marched out to relieve sentries on the external works, to make sallies, &c. The postern is often called the 'sally-port.'

POSTING, the forwarding of passengers from place to place by means of relays of horses. The application of the same words—post and postmaster—to the transmission of letters and to the stations where post-horses are kept, is, both on the continent of Europe and in Britain, a source of ambiguity. Posting was long in Britain, as it is yet in most parts of the continent, a government monopoly. A statute of Edward VI. fixed the charges of posting at 1*d.* per mile in 1548. The post-office act of 1656 confirmed the monopoly of furnishing post-horses for travelers in favor of the postmaster and his deputies; for a long time past, however, posting has been in the hands of private individuals. Post-chaises were first used in France, and introduced into England in the early part of last century. The payment is estimated per mile for each pair of horses, without regard to the number of persons conveyed; and a second pair of horses is charged at the same rate as the first.

Over the continent generally, posting is managed by the state, which retains the monopoly of supplying post-horses, and usually of forwarding the mails and diligences. The prices are fixed by government, as well as the number of horses that may be employed, which is regulated by the weight and number of persons conveyed.

POSTIQUE, an ornament in sculpture, marble, &c., applied or added after the work is otherwise finished.

POST-NUP'TIAL CONTRACT means, in Scotch law, an agreement, or, as it is called in England, a settlement, made between husband and wife after the marriage has taken place, with a view to affect the property of the parties, and generally to make provision for the wife and children. As a general rule, a post-nuptial settlement is not so effectual as an ante-nuptial settlement in securing the rights of a wife, because in the former case the marriage is considered a valuable consideration in point of law, and puts it on the footing of a sale. Nevertheless, if the husband is quite solvent, he and his future creditors will be bound by the provisions of a post-nuptial contract. See HUSBAND AND WIFE.

POST-O'BIT is a bond or security given by heirs and others entitled to reversionary interests, whereby, in consideration of a sum of money presently advanced, the debtor binds himself to pay a much larger sum after the death of some person, or of himself. Whenever, as is not unusual, the payment is uncertain, and depends on the obligor outliving somebody else, very high interest is required, or rather a very much larger sum is agreed to be repaid than what is advanced. These are generally usurious bargains; but the obligee or creditor can enforce payment of the full amount; though, if there is a gross case of inadequacy in the proportions amounting to fraud, a court of equity will interfere.

POST-OFFICE, a place for the reception of letters, and the management of the various departments connected with their dispatch and conveyance. The name originated in the posts (from Lat. *positum*, placed, fixed) placed at intervals along the roads of the Roman empire, where couriers were kept in readiness to bear dispatches and intelligence; but the posts of ancient times were never used for the conveyance of private correspondence. The first letter-post seems to have been established in the Hanse Towns in the early part of the 13th century.

A line of letter-posts followed, connecting Austria with Lombardy, in the reign of the Emperor Maximilian, which are said to have been organized by the princes of Thurn and Taxis; and the representatives of the same house established another line of posts from Vienna to Brussels, connecting the most distant parts of the dominions of Charles V. This family continue to the present day to hold certain rights with regard to the German postal system, their posts being entirely distinct from those established by the crown, and sometimes in rivalry to them.

In England, in early times, both public and private letters were sent by messengers, who, in the reign of Henry III., wore the royal livery. They had to provide themselves with horses until the reign of Edward I., when posts were established where horses were to be had for hire. Edward IV., when engaged in war with Scotland, had dispatches conveyed to his camp with great speed by means of a system of relays of horses, which, however, fell into disuse on the restoration of peace. Camden mentions the office of 'Master of the Postes' as existing in 1581, but the duties of that officer were probably connected exclusively with the supply of post-horses. The posts were meant for the conveyance of government dispatches alone, and it was only by degrees that permission was extended to private individuals to make use of them. A foreign post for the conveyance of letters between London and the continent seems to have been established by foreign merchants in the 15th c.; and certain disputes which arose between the Flemings and Italians, regarding the right of appointing a postmaster, and were referred to the privy-council, led to the institution of a 'chief-postmaster,' who should have charge both of the English and the foreign post. Thomas Randolph was the first chief-postmaster of England. The first proper postal communication for private letters in England came into operation 100 years after the institution of the foreign post.

The increased intercourse between the English and Scottish capitals, brought about by King James's accession, led to a great improvement in the system of horse-posts, but their services were still confined to the conveyance of government dispatches. That king, however, instituted a foreign post for letters going abroad from England, and conferred the office of postmaster of England for foreign parts on 'Mathewe de Quester the elder, and Mathewe de Quester the younger.' This appointment was considered by Lord Stanhope, the English chief-postmaster, to interfere with his functions, and a dispute and law-plea between the heads of the two establishments was settled in 1632, after Charles I. had become king, by the retirement of Lord Stanhope, and an assignment of their office by the De Questers, under royal sanction, to William Frizell and Thomas Witherings. In 1635, Witherings was authorized to run a post night and day between London and Edinburgh, 'to go thither and back again in six days.' Eight main postal lines throughout England were at the same time instituted, and the post was allowed to carry inland letters. Two years later, a monopoly of letter-carrying was established, which has been preserved in all the subsequent regulations of the post-office. The rates of postage were 2*d.* for a

single letter for a distance less than 80 miles, 4d. up to 140 miles, 6d. for any longer distance in England, and 8d. to any place in Scotland. An attempt, in 1649, by the Common Council of London to set up a rival post-office for inland letters, was suppressed by the House of Commons. A practice of farming the post-office revenues, which began in 1650, continued, as regards some of the by-posts, till the close of last century.

An important post-office statute was passed under the Protectorate in 1656, and re-enacted by 12 Car. II. c. 35. It ruled that there should be one general post-office and one postmaster-general for England, who was to have the horsing of all through posts and persons riding post. A tariff was established for letters, English, Scotch, Irish, and foreign, and the only non-governmental posts allowed to continue were those of the universities and the Cinque Ports.

In 1685, a penny-post was set up for the conveyance of letters and parcels between different parts of London and its suburbs. It was a private speculation, originating with one Robert Murray, an upholsterer, and assigned by him to Mr. William Docwray. When its success became apparent, it was complained of by the Duke of York, on whom the post-office revenues had been settled, as an encroachment on his rights; a decision of the Court of King's Bench adjudged it to be a part of the royal establishment, and it was thereupon annexed to the crown. In this way began the London district-post, which was improved and made a two-penny-post in 1801, and continued as a separate establishment from the general post down to 1854.

The first legislative enactment for a Scottish post-office was passed in 1695, prior to which time, the posts out of Edinburgh had been very few and irregular. About 1700, the posts between the capitals were so frequently robbed near the borders, that acts were passed both by the parliament of England and that of Scotland, making robbery of the post punishable with death and confiscation. The post-office of Ireland is of later date than that of Scotland. In the time of Charles I., packets between Dublin and Chester, and between Milford-Haven and Waterford, conveyed government dispatches; and after the Restoration, the rate of letter-postage between London and Dublin was fixed at 6d.

Act 3 Anne, c. 10, repealed the former post-office statutes, and put the establishment on a fresh basis. A general post-office was instituted in London for the whole British dominions, with chief offices in Edinburgh, Dublin, New York, and other places in the American colonies, and one in the Leeward Islands. The whole was placed under the control of an officer appointed under the Great Seal, called the Postmaster-general, who was empowered to appoint deputies for the chief offices. Rates higher than those formerly charged were settled for places in the British dominions, and also for letters to foreign parts. A survey of post-roads was ordered, for the ascertainment of distances. Letters brought from abroad by private ships were ordered to be handed over to the deputy-postmasters of the ports who were to pay the master a penny for each letter. A complete reconstruction of the cross-post system was effected in 1720, by Ralph Allen, postmaster of Bath, to whom the Lords of the Treasury granted a lease of the cross-posts for life: at his death, they came under the control of the postmaster-general. The rates of postage were further raised by act 1 Geo. III. c. 25, which also gives permission for the establishment of penny-posts in other towns, as in London. The Edinburgh penny-post was instituted in 1766, by one Peter Williamson, a native of Aberdeen, whom the authorities induced to take a pension for the good-will of the concern, and merged it in the general establishment.

Mail-coaches owe their origin to Mr. John Palmer, manager of the Bath and Bristol theaters, who, in 1783, submitted to Mr. Pitt a scheme for the substitution of coaches, protected by armed guards, for the boys on horseback, who till then conveyed the mail. After much opposition from the post-office authorities his plan was adopted, and Mr. Palmer, installed at the post-office as controller-general, succeeded in perfecting his system, greatly increasing the punctuality, speed, and security of the post, and adding largely to the post-office revenue.

In 1837, a plan of post-office reform was suggested by Mr. (afterwards Sir) Rowland Hill, the adoption of which has not only immensely increased the utility of the post-office, but changed its whole administration. Its principal features were the adoption of a uniform and low rate of postage, a charge by weight, and prepayment. The change met with much opposition from the post-office authorities, but was eventually carried by a majority of 100 in the House of Commons, becoming law by 3 and 4 Vict. c. 96. The new system came into full operation on January 10, 1840. Previously to the change, members of parliament had the right of sending their letters free, but this privilege of franking was entirely abolished. A penny was adopted as the uniform rate for every inland letter not above half an ounce. Facilities for prepayment were afforded by the introduction of postage-stamps, and double postage was levied on letters not prepaid. Arrangements were made for the registration of letters; and the

money-order office, by a reduction of the commission charged for orders, became available to an extent which it had never been before. As far back as 1792, a money-order office had been established as a medium for sailors and soldiers to transmit their savings, and its benefit had afterwards been extended to the general public; but the commission charged had been so high, that it was only employed to a very limited extent. The immediate result of the changes introduced in 1840 was an enormous increase in the amount of correspondence, arising in part from the cessation of the illicit traffic in letters, which had so largely prevailed before; but for some years there was a deficit in the post-office revenue. The reduction of postage-rates was, however, a reduction of taxation, and if the Exchequer lost revenue from one source, it gained it in other ways.

With the development of the railway system came the carriage of letters by train instead of by mail-coaches; and one novelty which arose out of this change was the adoption of traveling post-offices, forming part of the mail-train, where letters are arranged during transit, and which sometimes receive and drop the letter-bags while the train is going at full speed. The conveyance of the mails by railroad added greatly to the expenses of the post-office establishment; but, nevertheless, the former gross revenue of the post-office was exceeded in 1851, and the net revenue in 1863. According to the annual report of the postmaster-general for 1880-81, there are 912 head post-offices in the United Kingdom, 13,637 branch offices or receiving-houses, and about 13,160 road or pillar letter-boxes. Above 1776 millions of letters passed through the post-office in 1880-81—more than twice as many as in 1861, and thirteen times as many as in 1839, the last year of the dear postage. In 1880-81, the gross revenue of the post-office, exclusive of that yielded by the telegraphs was £6,733,427; the expenditure, also excluding the telegraphic service, £4,135,659; leaving a surplus of £2,597,768. The number of money orders transmitted within the United Kingdom, in the same year, was 16,329,476; the amount of money transmitted being £24,228,763. This is a decrease on previous years, probably caused by the introduction of postal orders. (See below, under *Money Orders*.)

The postal service of the three kingdoms is now under the immediate control of the postmaster-general, assisted by the general secretary of the post-office in London. There are also chief officers in Edinburgh and Dublin, with secretarial and other departmental staffs. The postmaster-general is a member of the privy council and sometimes a cabinet minister. He has a salary of £2500, and is the only officer connected with the department who leaves office on a change of government. The secretary is his responsible adviser, and has a salary of £2000. The receiver and accountant-general keeps account of the money received by each department, receiving remittances from branch and provincial offices, and taking charge of the payment of all salaries, pensions, and items of current expenditure.

The surveyors are the connecting link between the metropolitan and provincial offices, each postmaster, with some exceptions, being under the superintendence of the surveyor of his district. In 1881, the staff of officers employed in the post-office, including those engaged in telegraph work, was upwards of 47,000; of this number, about 12,000 were engaged solely in telegraph work, and about 11,000 were employed in London alone.

Act 24 Vict. c. 19 instituted a system of savings banks in connection with the post-office. The rate of interest payable to depositors is 2½ per cent., calculated on complete pounds and complete months, being a halfpenny per pound month. The number of depositors at the end of 1880 was 2,184,972; the amount of their deposits in the year, £10,219,631; and the number of banks, 6233. A novel extension of this system took place in 1880. Blank forms, with twelve ruled spaces, are now issued to intending depositors, who may secure their penny savings by affixing ordinary postage-stamps to the form. When the twelve spaces are filled, the form is presented at the bank, and credit is given for a shilling.

The Savings-bank Act (1880) permits the investment of small sums in government stocks; in Consols, Reduced, or New 3 per Cents. The sums invested must not be less than £10, and must not exceed £100 in any one year; the total sum for any one investor is limited to £300. The postmaster-general is empowered to insure the lives of applicants for not less than £20 or more than £100, and also to grant immediate or deferred annuities. See **POST-OFFICE INSURANCE**.

Halfpenny post-cards were introduced in 1870, and in the first year 75 millions were used. The number in 1880-81 reached 122 millions. The ordinary penny stamp is now a 'Postage and Inland Revenue' stamp, and may be used as a receipt stamp.

In 1869 the post-office acquired the existing electric telegraphs. About 30 millions of telegraphic messages were sent in the year ending March 31, 1881. Gross revenue, £1,633,884; working expenses, £1,189,425; net revenue, £444,459.

The home and foreign mail-packet service was, in the 17th and

18th centuries, in the hands of the post-office authorities, but was removed to the Board of Admiralty, under whose control it remained till 1860, when it was again restored to the post-office. Steam-vessels were first used for conveying the mail in 1821; and in 1833, mail-contracts were introduced, the first being with the Mona Steam Company to run steamers from Liverpool to Douglas in the Isle of Man. Of the home mail-packet contracts, the most important are those with the City of Dublin Steam-packet Company for conveying the Irish mails between Holyhead and Kingstown. The principal foreign contracts are for the Indian and Chinese mails, entered into with the Peninsular and Oriental Steam-navigation Company, the mails to North and South America, the West Indies, the Australian colonies, and the Cape.

The post-office statute of Queen Anne contains a prohibition repeated in subsequent acts, for any person employed in the post-office to open or detain a letter, except under a warrant from one of the principal secretaries of state. During last century, such warrants were often granted on very trivial pretences. In 1723, at Bishop Atterbury's trial, copies of his letters, intercepted at the post-office, were produced in evidence against him; and in 1735, it appeared that an organization existed, at an immense expense, for the examination of home and foreign correspondence. In 1732, the correspondence of Lord Temple, when Lord-lieutenant of Ireland was subjected to a system of post-office espionage. In the beginning of the present century, an improvement took place in this matter, and Lord Spencer introduced the custom, in 1806, of recording the dates of all warrants granted for the opening of letters and the grounds on which they were issued.

Since 1822, the warrants have been preserved at the Home Office; and a House of Commons' return in 1853 shows that, in the preceding ten years, only six letters were detained and opened—four in cases of felony, and two that they might be properly returned to those who claimed them. One of these cases of interference with the privacy of correspondence occurred in 1844, when Sir James Graham, as Home Secretary, issued a warrant for opening the letters of Mazzini, and caused certain information contained in them to be conveyed to the Austrian Minister, an act which involved the ministry of the day in considerable popular obloquy, and produced a wide-spread, though very groundless, distrust of the security of the ordinary correspondence of the country. See GRAHAM, SIR JAMES.

The following is a summary of the most important regulations of the British post-office, reference being made for the minute details to the *British Postal Guide*.

Inland Letters.—The rates of postage, prepaid, are 1d. for a letter weighing not more than 1 oz.; 1½d. when the weight is 1 oz. and not above 2 oz.; 2d. 2 oz. and not above 4 oz.; 2½d. 4 oz. and not above 6 oz.; 3d. 6 oz. and not above 8 oz.; 3½d. 8 oz. and not above 10 oz.; 4d. 10 oz. and not above 12 oz. A letter exceeding 12 oz. is charged 1d. per oz.; e.g., for a letter weighing 16 oz. the postage is 16d. A letter posted unpaid is charged double postage. Letters insufficiently stamped are charged double the deficiency on delivery. Redirected letters are charged additional postage at the prepaid rate; and this may either be prepaid, or charged on delivery. Letters for officers, soldiers, or seamen on actual service abroad, are redirected without charge, also with several restrictions, at home. By paying 1d. extra postage, letters may now be posted in the boxes attached to mail trains, in which sorting is performed.

No inland letter can be conveyed by post which is more than one foot six inches in length, nine inches in width, and six inches in depth, unless sent to or from one of the government offices.

Registration.—The registration fee of 2d.—in addition to the ordinary postage—prepaid in stamps, secures careful treatment to any letter, newspaper, or book-packet, and renders its transmission more secure, by enabling it to be traced from its receipt to its delivery. Letters may be registered for a fee of 2d. to any place in the British colonies, and for various rates of charge to different foreign countries. Letters containing coin, if not registered, are treated as if they were, and charged on delivery with a registration fee of eightpence; the same fee is charged on letters marked 'Registered' and posted in the usual way instead of being given to a post-office servant. If lost, the contents are only made good to the extent of 2s.

Foreign and Colonial Letters.—For the rates payable, reference is made to the *British Postal Guide*. Prepayment must be wholly in stamps. In some cases, prepayment is optional; in others, compulsory; and to some countries the whole postage cannot be prepaid. A letter posted unpaid or partially paid, directed to go by a route by which prepayment is compulsory, is returned to the writer, unless there be another route to send it by, by which prepayment is not required. Letters, however, for Australia and New Zealand, if prepaid as much as one rate, are forwarded, charged with the deficient postage and an additional rate. Letters for the Cape of Natal posted unpaid (wholly or in part), in addition to the deficient postage are charged 6d. each. Those for St. Helena and British West Indies, not included in the General

Postal Union, are charged 1s. each in addition to the deficient postage. No letter for any foreign country may be above two feet in length or one foot in width or depth.

Letters to be sent by private ship must be so marked; their postage varies from 2½d. upwards for half an ounce, and prepayment is obligatory in some cases, and in others not.

Letters to passengers on board the American or Mediterranean packets must be registered, and must be addressed to the care of the commander of the packet.

The post-office monopoly is applicable to letters only; and it does not include letters sent specially by private messenger, or letters concerning goods or merchandise sent to be delivered along with the goods which they concern.

Newspapers.—In 1870, the impressed duty stamp was abolished; and now, any newspaper published at intervals not exceeding seven days, and on a sheet or sheets unstitched, and registered at the General Post-office, is transmissible by post within the United Kingdom at a postage of one halfpenny for each transmission. The postage must be prepaid, either by an adhesive stamp or by a stamped wrapper. A packet of newspapers is not chargeable at a higher rate than a book packet—namely, one halfpenny for every 2 oz. or fraction of 2 oz. The cover, if there is one, must be open at both ends, and such that the packet can be easily removed for examination. There must be no writing outside or inside, except the address of the person to whom the newspaper is sent. Registration for inland circulation includes registration for transmission abroad. Newspapers for foreign countries and the colonies are subject to the same general regulations as for inland circulation, except that they may be published at intervals of thirty-one days, and printed on sheets stitched together. They must be posted within eight days from the day of publication.

Parliamentary Proceedings.—The printed proceedings of parliament, with the words 'Parliamentary Proceedings' written or printed on the cover, may circulate throughout the United Kingdom at the rate of one halfpenny for every 2 oz. or fraction of 2 oz. Prepayment is optional. Parliamentary notices may be forwarded by post under certain regulations and restrictions, the postage chargeable, and a registration fee of 6d., being payable in stamps.

Book-post.—This branch of the post-office was first established in 1848, and further improved by regulations issued in 1855, 1857, and 1870. The postage is now one halfpenny for every 2 oz. or fraction of that weight. A book-packet may contain books, paper, or parchment, whether plain, or written, or printed upon (provided there be nothing of the nature of a letter); maps, prints, &c. (but not in glass frames). Circulars, when wholly or in great part printed or lithographed, may also be sent by book-post, singly or in packets. The postage must be pre-paid by adhesive stamps, or by a stamped wrapper; if not prepaid, the packet is charged double the book-postage; if not sufficiently prepaid, it will be charged double the deficiency. If there is a cover, it must be open at the ends. No book-packet must exceed 5 lbs. in weight; it must not be over 1 foot 6 inches in length by 9 inches in width and 6 inches in depth; nor must it contain anything sealed against inspection. An entry on the first page of the book stating who sends it, or to whom it is given, is allowed. In order to secure the return of book-packets that cannot be delivered it is recommended to have the names and addresses of the senders written or printed outside. No writing in the way of a letter or communication is allowed; if any such communication be found within a packet, the whole will be charged the unpaid letter rate, and forwarded. The book-post has been extended to the colonies and to foreign countries at varying rates.

Colonial and Foreign Pattern and Sample Post.—This post extends to most colonies and foreign countries, at rates corresponding with those for book-packets. It is restricted to *bona-fide trade patterns or samples of merchandise*. Goods sent for sale, or in execution of an order (however small the quantity may be), or any articles sent by one private party to another which are not actually patterns or samples, are not admissible. The patterns are to be sent in covers open at the ends or sides; but samples of articles which cannot be placed in open covers, may be inclosed in transparent bags. Such articles as knives, scissors, &c., may be sent to places abroad, except France and the French colonies, provided they are so packed as to do no damage.

Post-cards, bearing a halfpenny impressed stamp, are transmissible within the United Kingdom. On the stamped side, the address alone is to be written. On the other side, any communication may be written or printed. Reply post-cards, which were introduced in 1882, allow the sender to prepay the reply. Foreign post-cards cost 1d. and 1½d.

The Parcels Post Act, passed in 1882, provides for the carriage of small parcels within the United Kingdom at the following rates: For parcels not exceeding 1 lb.—3d.; 3 lbs.—6d.; 5 lbs.—9d.; 7 lbs.—1s.

Money Orders.—Inland money orders may be obtained at any of the post-offices of the United Kingdom, on payment of the fol-

lowing commission: For sums under 10s.—2d.; for 10s. and under £2—3d.; for £2 and under £3—4d.; for £3 and under £4—5d.; and so on, up to £9 and under £10—11d.; £10—1s. Money orders may now be issued to the colonies, to most European countries, the United States, Egypt, &c., the commission being about three to four times the above rate. In applying for a money order, the surname and initial, at least, of one Christian name of the sender, and the name of the person to whom payable, must be given; but the designation of a firm will suffice, and the name of the person to whom the order is payable may be withheld, if it is to be paid through a bank.

A money order in the United Kingdom becomes void if not presented for payment before the end of the twelfth calendar month after that in which it was issued. Orders drawn on France or Italy must be paid within three months. The lower rates for inland money orders entail a loss on each transaction. Provision was further made for the issue of ten classes of 'postal notes' for small fixed sums, under Mr. Fawcett's Post-office (Money Orders) Bill of 1880.

Any person with a fixed residence may have a private box at the post-office on paying an appointed fee; but in no other case can a resident have his letters addressed to the post-office. See *POSTE RESTANTE*.

Letters containing anything liable to injure the contents of the mail-bag are not allowed to be sent by post. This comprehends glass in any form, vessels containing liquids, meat, fruit, explosives, sharp instruments, &c.

Telegrams.—The charge for the transmission of messages by telegraph throughout the United Kingdom is 1s. for the first twenty words, and 3d. for each additional five words, or part of five words. Press telegrams cost 1s. for 100 words by day, and for 75 by night.

The Universal Postal Union.—In October, 1874, a conference at Berne resulted in the establishment of the 'General Postal Union,' embracing all the European countries, with Egypt and the United States, and resulting in a great simplification of international postal arrangements. This was followed in June 1878 by the treaty of Paris, signed or subsequently adhered to by all the parties to the former treaty, with the addition of British India, the colonies of France, Spain, Holland, and Portugal, various British colonies, Persia, Japan, Liberia, Brazil, Peru, Mexico, &c., the new convention receiving the name of the 'Universal Postal Union.' Under this important treaty, all the consenting nations were declared to be 'a single postal territory for the reciprocal exchange of correspondence.' Equal rates, weights, and rules are established, and considerable reductions of postage have followed its adoption. Except in the case of lengthy sea transit, a uniform rate of 25 centimes (2½d.) is adopted for a letter of 15 grammes (½ oz.); of ten centimes (1d.) for post-cards; of five centimes (½d.) for packets of print, &c., of 50 grammes (2 oz.); and of 25 centimes (2½d.) for registration in Europe, and 50 centimes (5d.) for registration beyond Europe.—See *Her Majesty's Mails*, by Lewins; the *Postmaster-general's Annual Reports*; *Martin's Statesman's Year Book*; *Life of Sir Rowland Hill*; and the *History of Penny Postage*, by Sir R. Hill and G. B. Hill (1880).

POST-OFFICE, OFFENCES AGAINST. Owing to the conspicuous part which the post-office plays in modern civilization, a small code of laws belongs to it, the substance of which is as follows: Every person employed by the post-office who steals a post-letter, is guilty of felony; and if it contain money or a valuable chattel, the punishment is increased. So whenever letters are stolen by strangers out of the custody of the post-office or its officers. The moment a letter is put into the post-office or delivered to the postmaster, the protection of the statutes commences. Many nice questions have, however, arisen as to the application of the rule to special circumstances, and as to what constitutes an employment by the post-office. Whoever steals, secretes, or destroys printed papers or newspapers sent by post, commits a misdemeanor. So if a letter-carrier delay the delivery wilfully, or if an official messenger disclose or intercept a telegraphic message, or violate the rules on that point. Receivers of letters improperly taken or stolen from the post-office, are guilty of felony. By the 1st Vict. c. 33, s. 2, any person conveying otherwise than by post a letter not exempted from the exclusive privilege of the post-master-general, incurs a penalty of £5 for every letter. This exclusive privilege of carrying letters extends to letters only, and not to printed books or newspapers. There are also exceptions to the general rule, that letters can only be sent by the post-office. Thus, one may send a letter by a private friend, and not by the post-office. So letters sent by messenger on purpose on the private affairs of the sender or receiver, commissions and legal writs, merchants' letters sent by vessels or along with goods, are excepted. But no person is authorized to collect and send these excepted letters, though in the legal manner described, for this is doing the work of the post-office. Moreover, there are certain persons expressly prohibited from carry-

ing letters even gratuitously, as common carriers, except the letters relate to goods in their carts or wagons; owners, masters, or commanders of ships, except such letters relate to goods on board; and passengers on board ships. Statutes and rules made thereunder secure the monopoly to the postmaster-general of sending telegraphic messages, and telegrams are put nearly on the footing of letters.

POST-OFFICE INSURANCE is a valuable addition to the many useful services which our postal establishments has been enabled to render within the last few years. Book-post, sample-post, money-orders, and postal savings-banks, all additions to the original letter-post, and newspaper-post, have been found to work so satisfactorily, that the legislature has been encouraged to intrust to the same organization a new system of insuring lives and granting annuities—specially intended to foster provident habits among persons whose savings can be but small.

In 1853, an act of parliament made an improvement in the then existing state of insurance law, by facilitating the purchase of government annuities through the medium of the savings-banks; and in 1864, another statute gave a great extension to those portions of the system which had been found to work well, effecting at the same time alterations in those which had exhibited certain defects during eleven years' working. Great facilities are introduced by this act for securing annuities by small payments. Not only may the National Debt Commissioners employ the trustees of savings-banks to receive and pay the moneys, at a certain rate of remuneration; but the Postmaster-general joins in the arrangement, acting as a medium between the public on the one hand and the commissioners on the other. Ample tables and regulations have been printed, for the guidance of the Commissioners, the Postmaster-general, and the local postmasters throughout the kingdom. On the completion of these tables and regulations in 1865, the practical working of the system began. The tables of the premiums to be charged for life-insurances, for immediate annuities, for deferred annuities, and for deferred monthly allowances, are sold by Messrs. Eyre and Spottiswoode, the government printers, for 5½d. (the cost of the paper and printing); but similar tables are kept for inspection at the local post-offices without charge.

In regard to insurance, distinct from annuities, persons of either sex may insure through the medium of the post-office. The limited ages are from 16 to 60, and the limited sums from £20 to £100. In order to afford every possible facility in the payment of the premium, minute calculations have been made of the exact sum to be paid at each instalment, by yearly, quarterly, monthly, or fortnightly payments, and terminable or not at a particular age. In order that there may be some limit to the labor thus placed on the postal authorities, no periodical instalment is made smaller than two shillings. No one life can be insured for less than £20 in the whole; but when a life has been insured for £20, further insurances may be effected on the same life from time to time, until the whole sum for which it is insured amounts to £100. The following is a tabulated example of nine different modes of paying the premium on one particular insurance, to suit the convenience of the insurer. A man in his 30th year may insure £100 to his survivors at his death:

	£	s.	d.
1. By a single payment of.....	48	3	7
2. By an annual payment for life of.....	2	6	7
3. By a quarterly " ".....	0	13	0
4. By a monthly " ".....	0	4	4
5. By a fortnightly " ".....	0	2	2
6. By an annual payment, until the insurer reaches 60 years, of.....	2	13	10
7. By a quarterly payment, until the insurer reaches 60 years, of.....	0	15	0
8. By a monthly payment, until the insurer reaches 60 years, of.....	0	5	0
9. By a fortnightly payment, until the insurer reaches 60 years, of.....	0	2	6

If an insurer who has duly paid all instalments for five years, should desire, or be compelled by circumstances to withdraw from the engagement, a portion of the past premiums will be repaid to him—never less than one-third of the total amount.

In regard to immediate annuities, persons of either sex may purchase annuities of not more than £50, and for lives from 10 years old and upwards. The premiums necessarily vary with sex, age, and amount. Thus, a man aged 65 can purchase an immediate annuity of £10, paid half-yearly, for £88, 18s. 4d.; whereas, a woman of the same age would have to pay £103, 16s. 8d. Two or more small annuities may be purchased for the same life, provided the total amount does not exceed £50. Any two persons may purchase an annuity on their joint lives, with or without continuance of the annuity to the survivor.

Deferred annuities form another element in the scheme. These annuities are very varied in kind, and the amount of premium de-

depends on a great number of conditions—amount of annuity; age and sex of the person; length of term for which the annuity is deferred (that is, the number of years which are to pass before the commencement of the annuity); mode in which the premium is to be paid; and the condition whether or not there is to be any return of purchase-money under certain contingencies. As examples, take the following: A man aged 30 may purchase a deferred annuity of £10, to commence on his reaching the age of 60, and due half-yearly, for one immediate payment of £21, 3s. 4d., or an annual payment of £1, 8s. 4d.; in the case of a woman, the immediate or total payment would be £32, 8s. 4d., and the annual payment £1, 17s. 6d. If the person on whose life the annuity is to depend should die before the annuity itself commences, all the premiums paid up to that date may be returned to his or her representatives provided a contract to this effect is made in the first instance. The premiums are necessarily higher for such a contract. The four sums just mentioned, where past premiums are not returnable, would be raised respectively to £40, 9s. 2d., £2, 0s. 10d., £47, 0s. 10d., and £2, 7s. 6d., with the returnable clause included.

Many persons in humble life would prefer that the annuities due to them should come more frequently than half-yearly. To suit this class, a system of deferred monthly allowances is established. A man aged 30 may purchase a deferred allowance of £2, 7s. 3d. per month, to commence when he reaches the age of 60, by a payment of 8s. per month, until he reaches that age; the same monthly payment by a woman would realize a monthly allowance of £1, 16s. 7d. If the returnable clause (above noticed) is included in the contract, the man's monthly allowance would be £1, 14s. 2d., and the woman's £1, 9s. 4d., for the like payment of 8s. per month. In regard to married couples, a husband and wife may each be insured to the full amount of £100, and may each purchase an annuity of £50, or a monthly allowance of £4, 3s. 4d.

Persons whose lives are insured, or to whom annuities are granted, through the post-office, have direct government security for the payment of the money at the proper time; and this is one of the many valuable features of the system. It is not necessary here to describe the exact routine of proceedings for making an insurance or purchasing an annuity; the postmasters whose post-offices have been raised to the rank of insurance offices, are fully instructed in the matter, and will give all requisite information to applicants. We may add, that the *British Postal Guide*, an authorized publication, issued quarterly at 6d., gives a considerable list of tables of premiums payable at various ages for various kinds of insurance and annuity.

POSTULATE. This word occurs in Geometry, and signifies something that is *demanded*, and must be granted before the demonstrations of the science can be wrought out. The postulates of Euclid have reference to certain constructions indispensable to the reasoning. They are these three: 'A straight line may be drawn from one point to another;' 'A line already drawn may be produced;' and 'A circle may be described from a given center, with a given radius.' The object of laying down these in the shape of demands, is to fulfil one great condition of demonstrative science, which is, that nothing shall be proceeded on, in the course of the reasoning, without being explicitly stated at the outset. It has been noticed by critics that the three postulates of Euclid do not exhaust the demands actually made in the course of his demonstrations. Thus, in the 4th and 5th Propositions, Book I., this postulate is assumed: 'Any figure may be removed from place to place without alteration of form, and a plane figure may be turned round on the plane.'

The postulate is something different from the axiom. An axiom is a general and fundamental principle, such as no one can deny, and serving as the ultimate foundation (in Logic, the major premise) of deductive inferences; as, for example, 'Things equal to the same thing are equal to one another.' The postulate, in Euclid's sense, is a special accessory to the reasoning, different from the axioms.

But in Philosophy, the postulate takes a much wider sweep, and expresses the most fundamental concessions implied in all reasoning, being pre-requisite in order to the establishment of the axioms themselves.

Thus, it is a postulate necessary to reasoning and discussion that a reasoner shall be consistent with himself—that he shall not affirm a thing one minute and deny it the next. The so-called Laws of Thought—Identity, Contradiction, and Excluded Middle—are so many forms of the postulate of consistency. These laws are tantamount to demanding that the same thing shall not be maintained in one form, and denied in another. If we say this room is hot, we must not, at the same time, say that it is not hot. So the ordinary law of the syllogism, 'Whatever is true of all the members of a class, is true of each,' is not so much an axiom as a postulate of consistency; we must be prepared to provide individually the statements that we have affirmed collectively.

The ultimate premises of all truth and reasoning may be put in the form of postulates, as follows: 1. Present Consciousness must be admitted as a ground of certainty. 'I am thirsty,' 'I hear a sound,' as facts of present consciousness, are to be held as trustworthy in the highest degree, or as amounting to the highest certainty. 2. But present consciousness is not enough; it must further be conceded that Past Consciousness is a ground of certainty. Present consciousness does not amount to an experience of value for future purposes, unless taken with past. Now, although a remembrance that is long past is often uncertain, a recent remembrance must be pronounced absolutely certain, not less than a present consciousness. That 'I was thirsty a short time ago,' I must be certain of, in order to establish the induction, 'that water quenches thirst.' 3. It must further be conceded, that 'What has been in the past, all circumstances holding the same, will be in the future.' That a thing has been, does not imply that it will be. We may admit that the sun has risen to-day, and rose yesterday, and so on, and without inconsistency, refuse to admit that it will rise to-morrow. People are generally well enough disposed to treat this as a certainty; indeed, there is a strong natural tendency of the mind to expect that the future will resemble the past, which, when corrected and regulated by experience, constitutes our belief in causation and the uniformity of nature. Still, a blind instinct is no guarantee for truth; and as the assertion of the future is a distinct position, it should be formally assumed in a separate postulate. However often a thing may have happened, we still make a leap, and, so to speak, incur a risk in venturing to predict its future recurrence. Our confidence no doubt increases with repetition, but nothing can obliterate the line between what *has been* and what *is to be*.

These three Postulates of Experience, coupled with the Postulate of Consistency, seem adequate as a basis of all the recognized axioms and truths of experience. In other words, the concession of them is enough to commit any one to the reception of all inductive and deductive evidence.

POSTULATION (Lat. 'an asking'), in Canon Law, means a presentation or recommendation addressed to the superior, to whom the right of appointment to any dignity belongs, in favor of one who has not a strict title to the appointment. It is one of the forms of proposing to the pope persons nominated, but not, strictly speaking, elected, to a bishopric. It is also used in the case of elections in which the candidate, although regularly chosen by the electors, yet labors under some legal disability which involves the necessity of a dispensation. The presentation of candidates for the episcopacy, as it exists in the Roman Catholic Church in Ireland, is called postulation.

PO'STURES, the name given to the attitude observed in worship, whether private or public, but especially the latter. They are the natural expressions of the feeling which accompanies or characterizes the particular devotion in which they are employed, and are used by suppliants to man as well as to God. Four postures are found to have been used by the ancient Christians in their prayer—the standing, the kneeling, the bowing or inclined, and the prostrate. Of these, the ordinary one was kneeling; but for it was substituted, during the Easter-time and on the Sundays, a standing posture, which was understood to symbolize the resurrection of our Lord. To this usage we find allusions as early as the time of Justin the Martyr. In the paintings of the catacombs, and on the ancient enamelled glasses found therein, the standing posture in prayer is accompanied by outstretched and upraised hands. The bowing posture was rather a special act of reverence accompanying a particular address or a particular part of an address, than a sustained posture. It occurred at frequent intervals in the ancient liturgy, and is still used in the Roman mass as well as (even more profusely) in those of all the various rites, Greek, Syrian, Coptic, Armenian, and Russian. The prostrate posture was the attitude of the deepest humiliation, and was mainly used by the Penitents (q. v.), especially in that grade of public penance which was known under the name 'prostration.' It is also used still in the solemn ordination of subdeacons, deacons, and priests, as performed in the Roman Catholic Church. The question as to the use of particular postures was a subject of much controversy between the Puritans and the Church of England; and has recently been revived in the Presbyterian Church of Scotland.

POT-WALLERS, or **POT-WALLOPERS** (from *pot*, and Old English *wall*, to boil or bubble), the popular designation of a class of electors forming the constituency of various English boroughs—as Ilchester, Honiton, Tregoney, Old Sarum—before the Reform Act of 1832, whose qualification as housekeepers was considered to be established by their boiling a pot within the limits of the borough over a fireplace erected in the open air. The doing so was regarded as evidence that the elector was in circumstances to provide for his own subsistence, and not necessitated to apply for parochial relief.

POTASH AND PEARL-ASH, in Commerce. See POTASSIUM. The chief source of this important article in Britain is Canada, where it is derived from the vast quantities of wood cut down and burned in clearing the forest for culture, and also from the branches of the trees felled for timber. The ashes, mixed with a small quantity of quicklime, are put into large wooden cisterns, and covered with water. The whole is well stirred up, and allowed to settle; the next day, the clear liquor is drawn off, and evaporated to dryness in iron pots, whence it is called *potash*. When a sufficient quantity is got to fill a cask of 5 cwt., it is fused at a red heat, and poured into the cask. The mass when cold is colored gray externally, but when broken shows a pinkish tint internally. It is very deliquescent, and consequently the casks require to be nearly air-tight. In this state, potash contains a large quantity of foreign materials, amounting to about 40 per cent., amongst which sulphur and carbonaceous matter predominate. This is the crude American potash of commerce. If it is calcined by a reverberatory furnace, the sulphur is driven off, and the carbonaceous matter burned out; the carbonic acid, however, combines with the potash, and forms it into a carbonate. To form it into *pearl-ash*, it is then broken up, and dissolved in water in a wooden cistern, having a perforated bottom, covered with straw, through which it filters, and is afterwards evaporated in flat-bottomed iron pans. As it approaches dryness, it is stirred with iron rods, which break it up into round lumpy masses of a pearly-white color, and in this state it is the *pearl-ash* of commerce, and contains about 50 per cent. of pure potassa.

All land-plants yield potash when burned, and many in much greater proportions than the timber trees of North America; but the circumstances in which the materials are obtained, give an advantage to our colonial manufacturers, which hitherto has enabled them to compete with the whole world. The quantity imported annually of 'pots' and 'pearls' as they are technically called, reaches the value of nearly half a million sterling. See POTASSIUM.

POTASSIUM (symb. K, equiv. 39, sp. gr. 0.865) is one of the alkaline metals. The letter K is selected as its symbol, as being the first letter of *Kali*, the Arabic word for potash, the letter P being preoccupied as the symbol for phosphorus. The following are the chief characters of this metal. It is of a bluish-white color, and presents a strong metallic lustre. At 32°, it is brittle, and has a crystalline fracture; at a somewhat higher temperature, it is malleable; at 60°, it is soft, and of the consistence of wax; at 180°, it is completely liquid; and at a red heat, it becomes converted into a beautiful green vapor. Its affinity for oxygen is so great, that on exposure to the air it immediately becomes covered with a film of oxide. When heated, it burns with a violet flame. Its intense affinity for oxygen is well shown by throwing it into water, on which, from its low specific gravity, it floats. The metal abstracts oxygen from the water, and forms oxide of potassium (potash); while the liberated hydrogen carries off a small portion of the volatilized potassium, and taking fire from the heat evolved by the energetic chemical action, burns with a brilliant violet flame. The experiment is a very beautiful one, the burning metal swimming about rapidly on the water, and finally disappearing with an explosion of steam when the globe of melted potash becomes sufficiently cool to come in contact with the water. At an elevated temperature, this metal removes oxygen from almost all bodies into the constitution of which that element enters; and in the laboratory it is often employed to remove any traces of oxygen from hydrocarbons, by distilling the latter with a small quantity of the metal. From the above facts, it is obvious that potassium must always be kept in some fluid, such as purified rock-oil or naphtha, which contains no oxygen.

Potassium does not occur in the native state, and can only be obtained by the reduction of its oxide, potash. There are three principal modes of reduction, all of which deserve a brief special notice, either on historical grounds or for their practical value.

1. Davy, in 1807, decomposed a fragment of hydrate of potash, by the current of a strong voltaic battery, into potassium, which separated as globules at the negative pole, and oxygen, which was evolved at the positive pole. This mode of procuring potassium yields only very small quantities, and is expensive; but the experiment was a most important one for the progress of chemistry, as showing for the first time that potash is not, as was previously supposed, a simple body.

2. Stimulated by Davy's discovery, Gay-Lussac and Thenard, in the following year (1808), succeeded in obtaining the metal by purely chemical means in greater abundance, by decomposing potash by means of metallic iron at a white heat. The oxygen of the potash combines with the iron, and the potassium in a gaseous form is condensed in a receiver filled with naphtha, and kept cool.

3. The method now usually adopted consists in the distillation of a mixture of carbonate of potash and charcoal at a white heat, in an iron retort. If proper proportions are taken, the mixture is

wholly converted into carbonic oxide and potassium, as is shown in the equation:

Potassium forms two compounds with oxygen, viz., a protoxide, KO, which constitutes potash, and is strongly basic, and a teroxide, K₂O₃, which does not combine with acids, and of which it is unnecessary to say more than that it is a yellowish-brown substance, which is found when the metal is burned in an excess of oxygen gas.

Potash can be procured in the anhydrous form by oxidizing thin slices of the metal in air perfectly free from moisture or carbonic acid. It is white, very deliquescent, and caustic. When moistened with water, it becomes incandescent, and the water cannot be expelled by any degree of heat. A far more important substance is the *Hydrate of Potash* or *Caustic Potash* (KO,HO). This is commonly prepared by dissolving carbonate of potash in ten times its weight of water, and gradually adding to the boiling solution a quantity of slaked lime, equal in weight to half the carbonate of potash used. The resulting compounds are carbonate of lime, which falls as a precipitate, and hydrate of potash, which remains in solution; the changes being expressed by the equation:

The clear supernatant fluid is removed by decantation, or by means of a syphon, into a clean silver or iron basin, and is rapidly evaporated till it flows tranquilly like oil; it is then either cast into cylinders in metallic moulds, or is poured upon a cold slab, and solidifies on cooling. It may also be obtained in acute rhombohedrons, if allowed to crystallize from a hot concentrated solution; the crystals containing four atoms of water. A solution of hydrate of potash being one of our most important chemical re-agents, it is very essential that it should be obtained pure. When obtained in the method that has been described, it is apt to be contaminated with carbonic, sulphuric, hydrochloric, and silicic acids, lime, alumina, oxides of iron, &c., any of which substances can be detected by the appropriate tests. Pure caustic potash is, however, perfectly soluble in alcohol, which does not dissolve any of the above-named impurities. Hence, by forming an alcoholic solution of potash, and by evaporating it in a silver vessel till the whole of the alcohol is expelled, we obtain this substance in a state of purity.

Hydrated potash, on solidifying after fusion, occurs as a hard, grayish-white, opaque body, with a crystalline fracture, which may be readily again fused into a colorless oily fluid, but which only volatilizes at a very high temperature. It is soluble in about half its weight either of water or of alcohol, and rapidly absorbs both carbonic acid and moisture from the atmosphere. It acts as a powerful caustic, and quickly destroys both animal and vegetable tissues, and hence its solutions can only be filtered through pounded glass or sand. Its affinities are so powerful that few vessels are capable of resisting its influence. Its solution must be preserved in glass bottles, into the composition of which no oxide of lead enters, as it has the property of dissolving this oxide out of the glass. Vessels containing silica (porcelain, earthenware, &c.) are decomposed, and platinum itself is oxidized when heated in contact with it. The principal uses of this substance are thus briefly summed up by Professor Miller. 'Potash decomposes the fixed oils, and converts them into soluble soaps; when fused with silicious minerals, it displaces the bases, and combines with the silica, forming silicate of potash. Potash is extensively employed in the arts: to the soap-boiler and the glass-maker, it is indispensable; when combined with nitric acid, it enters largely into the manufacture of gunpowder; and, in greater or less quantity, it furnishes important aids to a variety of processes employed in the manufactures of the country. In the laboratory, potash is in constant use for absorbing acid gases, such as carbonic acid, and for separating the metallic oxides from solutions of their salts, since, owing to the powerful affinity of the alkali for acids, it readily decomposes the salts of all the metals which produce oxides insoluble in water.'—*Elements of Chemistry*, 2d edition, vol. ii. p. 353.

The salts which potash forms with acids are for the most part readily soluble in water, and colorless, unless (as, for example, in permanganate of potash) the acid is colored. Most of them are crystallizable, and they all communicate a violet tint, characteristic of potash, to the flame of spirit of wine and to that of the blowpipe. Many of them occur in the animal and vegetable kingdoms, and the ashes of plants contain them in large quantity. We shall now briefly notice the most important of these salts. *Carbonate of Potash* (KO,CO₂) is obtained by burning plants in dry

pits, dissolving the ashes in water, evaporating till the sulphates, chlorides, &c., separate in crystals, and then boiling the mother liquid to dryness in iron pots. See POTASH. The quantity of pure carbonate of potash contained in it is liable to great variation, and the process termed *Alkalimetry* has been invented, with the view of rapidly determining the amount of this salt, on which the commercial value of the pearl-ash depends. Different plants furnish varying quantities of this salt, and the leaves and young shoots are the parts which furnish it most abundantly. The potash is, of course, obtained by the plants from the soil, which, when capable of supporting vegetable life, always contains that substance; and does not exist in the plants in the form of carbonate, but in union with various organic acids (such as acetic, malic, tartaric, and other acids), which, by incineration, become decomposed into carbonates. The purified carbonate of potash, employed in pharmacy and for chemical purposes, is prepared from the crude salt by adding an equal quantity of cold water, agitating, and filtering. By this means, all the less soluble foreign bodies are got rid of. The solution is then boiled down to a small bulk, and allowed to cool, when the carbonate separates in small crystals, containing 20 per cent. of water, and represented by the formula $\text{KO}_2\text{CO}_3 + 2\text{Aq}$. Carbonate of potash is extremely deliquescent, and is soluble in less than its own weight of water, but is insoluble in alcohol. It has an acrid, alkaline taste, and its reaction upon test-paper is strongly alkaline. It is a compound of great importance, both as a chemical re-agent, and as entering largely into the preparation of most of the other compounds of potash, and into the manufacture of soap and glass.

Bicarbonate of Potash ($\text{KO}_2\text{CO}_3 + \text{HO}_2\text{CO}_3$) is obtained in white rhombic prisms, by passing a current of carbonic acid gas through a strong solution of carbonate of potash. These crystals are permanent in the air, but are decomposed by heat; water and carbonic acid being evolved, and the simple carbonate left. This salt is much less soluble than the carbonate, requiring four parts of cold water for its solution, which is nearly neutral to test-paper, and has a much milder taste than the preceding salt. It is employed largely in medicine for making effervescing draughts. *Sulphate of Potash* (formerly known as *sal polychrest*) is obtained by dissolving in water the acid residue of bisulphate of potash ($\text{KO}_2\text{SO}_4 + \text{HO}_2\text{SO}_4$), which is left in the retort in the preparation of nitric acid. This solution, on being neutralized with carbonate of potash, furnishes hard transparent crystals of this salt. From its extreme hardness, this salt is used in medicine (as, for example, in Dover's Powder), for the purpose of finely comminuting vegetable matters. The *Bisulphate of Potash*, from which the preceding salt is obtained, is the *sal enizum* of the older chemists. Except that it is occasionally employed as a flux it is of no special importance. *Nitrate of Potash* has been already described under the head NITRE. *Chlorate of Potash* (KO_2ClO_3) occurs in white rhomboidal tablets of a pearly lustre. It has a cooling taste like that of nitre. It fuses at a gentle heat without decomposition, but on increasing the heat, it gradually gives off all its oxygen, and is converted into chloride of potassium, according to the equation:

It is not very soluble, as it requires for its solution 16 parts of cold and 1·7 parts of boiling water. It even exceeds nitrate of potash as an oxidizing agent; and if combustible substances, such as carbon, sulphur, or phosphorus be heated, or forcibly rubbed with it, a detonation or explosion occurs. This salt is employed in the manufacture of lucifer-matches, in certain operations in calico-printing, and for filling the friction-tubes employed for firing cannon: the best mixture for these tubes consisting of 2 parts of this salt, 2 of sulphide of antimony, and 1 of powdered glass.

A mixture known as *White Gunpowder*, consisting of chlorate of potash, dried ferrocyanide of potassium, and sugar, has been employed for blasting purposes, but its preparation is accompanied by so much danger, that it is seldom used. This salt does not occur as a natural product, but may be obtained by passing a current of chlorine gas through a hot solution of caustic potash; 6 eq. of chlorine combining with 6 eq. of potash to form 5 eq. of chloride of potassium, and 1 eq. of chlorate of potash, according to the equation: $6\text{Cl} + 6(\text{KO}_2\text{HO}) = 5\text{KCl} + \text{KO}_2\text{ClO}_3 + 6\text{HO}$. The two salts are easily separated by crystallization, as the chlorate is comparatively insoluble, and the chloride extremely soluble. *Hypochlorite of Potash* (KO_2ClO) can only be obtained in solution. Under the title of *Eau de Javelle*, it is sold as a bleaching agent. It is obtained by passing chlorine gas through a cold dilute solution of carbonate of potash, when chloride of potassium and hypochlorite of potash are formed, from which the chloride may be removed by crystallization. The *Phosphates of Potash* formed by the different varieties of phosphoric acid, are sufficiently noticed in the articles PHOSPHATES (in Physiology) and PHOSPHORUS. The *Silicates of Potash* are important compounds in connection with the manufacture of glass; they also enter into

the composition of Fuch's *Water-glass*, or *Soluble Glass*, and have been employed by Ransome and others as a coating by which the decay of magnesium and other limestones may be prevented. The *Chromate* and *Bichromate of Potash* are sufficiently noticed in the article CHROMIUM. The haloid salts of potassium may be passed over very briefly. The *Chloride of Potassium* (KCl) is obtained in large quantity in the preparation of chloride of potash, or may be procured by burning potassium in chlorine gas, when the result of the brilliant combustion which takes place is this salt. In its general characters, it closely resembles common salt (NaCl), except that the former communicates a violet, and the latter a yellow tint to the flame of alcohol. It is a constituent of sea-water, of salt marshes, and of many animal and vegetable fluids and tissues. The *Bromide* and *Iodide of Potassium* are sufficiently noticed in the articles BROMINE and IODINE.

Fluoride of Potassium (KFl) possesses the property of corroding glass. There are no less than five *sulphides of potassium*, commencing with the protosulphide (KS), and terminating with the pentasulphide (KS₅). The latter is the main ingredient in the *Hepar sulphuris*, or *Liver of sulphur*, used in medicine. It is a brown substance, obtained by fusing, at a temperature not exceeding 432°, 3 eq. of potash and 12 eq. of sulphur, the resulting compounds being 2 eq. of pentasulphide of potassium (2KS₅) and 1 eq. of hyposulphide of potash (K₂S₂O₃). From this mixture, the pentasulphide may be removed by alcohol, in which it dissolves. The *Yellow* and the *Red Prussiate* (or the *Ferrocyanide* and *Ferridcyanide*) of Potash are noticed in the articles FERROCYANOGEN and FERRIDCYANOGEN. The *Cyanide of Potassium* (KCy) may be procured by heating potassium in cyanogen gas, when brilliant combustion occurs, and the resulting product is this salt. It may, however, be more cheaply and easily prepared by Liebig's process, which does not, however, yield it pure, but mixed with cyanate of potash—an impurity which is of no consequence for most of the applications of cyanide of potassium, as, for example, electro-plating and gilding. Eight parts of anhydrous ferrocyanide of potassium are mixed with three parts of dry carbonate of potash; the mixture is thrown into a red-hot earthen crucible, and kept in fusion till carbonic acid gas ceases to be developed, and the fluid portion of the mass becomes colorless. After a few moments' rest, the clear fused salt is decanted from the heavy black sediment, which consists chiefly of metallic iron in a state of minute division. It has recently been derived from an unexpected source. In some of the iron furnaces where raw coal is used for fuel in the hot-blast, a saline-looking substance is sometimes observed to issue in a fused state from the tuyere-holes of the furnace, and to concrete on the outside. Dr. Clark of Aberdeen has shown that this substance is mainly cyanide of potassium. This salt forms colorless deliquescent crystals very soluble in water. It exhales an odor of hydrocyanic acid, and is said to be as poisonous as that acid. Its great deoxidizing power at a high temperature renders it a valuable agent in many of the finer operations of metallurgy.

The following are the ordinary tests for the potassium compounds: 1. Solution of tartaric acid added in excess to a moderately strong solution of a potassium salt, gives after some time a white crystalline precipitate of cream of tartar. See TARTARIC ACID. The result is hastened by stirring or shaking. 2. Solution of bichloride of platinum gives a crystalline yellow precipitate, which is a double salt of bichloride of platinum and chloride of potassium. If not previously acid, the mixture to be tested should be acidulated with hydrochloric acid. See PLATINUM. 3. The violet tint occurring in the presence of potassium in the outer flame of the blowpipe, or in the flame of spirit, has been already noticed. 4. The spectrum of a flame containing potassium exhibits a characteristic bright line at the extreme limit of the red, and another one at the opposite violet limit of the spectrum. See SPECTRUM ANALYSIS.

The British Pharmacopœia contains the following preparations of this metal. *Caustic Potash*, or *Hydrate of Potash* (KO_2HO), which occurs in hard white pencils. From its being fused before being poured into the moulds which give it the form of pencils, it is often termed *Potassa fusa*. From its power of dissolving the animal tissues, it is sometimes used as a caustic, although its great deliquescence renders it somewhat difficult to localize its action to the desired spot. In bites of venomous serpents, mad dogs, &c., it may be applied with advantage, and it is useful in destroying warts and fungoid growths of various kinds. It can be employed with greater safety than the lancet in opening certain abscesses, especially those of the liver. *Solution of Potash*, commonly known as *Liquor potassæ*, is obtained by the process already given for the preparation of hydrate of potash—namely, by the action of slaked lime on a boiling solution of carbonate of potash. Its sp. gr. is 1·053, and hence the solution is somewhat weaker than that of the London Pharmacopœia, whose sp. gr. is 1·063, and which, according to the experiments of Mr. Phillips, contains 6·7 grains of potash in 100 grains of the solution. 'One fluid

ounce requires, for neutralization, 48.25 measures of the volumetric solution of oxalic acid.

Liquor potassæ, in combination with a tonic infusion, is of service in cases of dyspepsia which are accompanied with excessive acidity of the stomach, such, for example, as often occur in habitual spirit-drinkers. It is also frequently given with a view of rendering the urine alkaline, or of diminishing its acidity in cases in which that secretion is too acid. In chronic skin-diseases, especially those of a scaly nature, it often gives relief, if given in full doses, and for a sufficient time; and in chronic bronchitis it is given with advantage for the purpose of diminishing the viscosity of the bronchial mucus. The usual dose is ten drops, gradually increased to as much as a fluid drachm. Infusion of orange peel and table-beer are fluids which conceal its unpleasant taste. Veal-broth has also been recommended as a medicine in which to present it. Its too prolonged use renders the urine alkaline and sedimentary (from the deposit of phosphate of lime), and tends to impoverish the blood. *Sulphurated Potash*, or *Potassa sulphurata*—which is the new name for the sulphuret of potassium, or liver of sulphur (*Hepar sulphuris*)—is obtained by fusing together carbonate of potash, and sublimed sulphur. It occurs in solid greenish masses, which are liver-brown when recently broken. It is alkaline and acid to the taste, readily forming with water a yellow solution, which has the odor of sulphuretted hydrogen, and evolving that gas freely, on the addition of an excess of hydrochloric acid. It is sometimes given internally in doses of three grains (in the form of a pill made with soap), in obstinate skin-diseases, but is chiefly used as a lotion, bath, or ointment for these diseases. It must be recollected that this compound is an energetic narcotico-acrid poison, its action being very like that of sulphuretted hydrogen. *Acetate of Potash* ($\text{KO}, \text{C}_2\text{H}_3\text{O}_2$) is obtained by the action of acetic acid on carbonate of potash, and occurs in white foliaceous satiny masses. In its passage through the system, it is converted into carbonate, and thus renders the urine alkaline. In small doses, as from a scruple to a drachm, it acts as a diuretic, and is of service in some forms of dropsy. Combined with other potass-salts, it is much given in acute rheumatism.

Carbonate of Potash ($\text{KO}, \text{CO}_2 + 2\text{Aq}$) is employed in medicine in the same cases as those in which solution of potash is used. In large doses, it acts, like caustic potash, as an irritant poison. It is frequently employed in the preparation of effervescing draughts, 20 grains of this salt being neutralized by 17 grains of citric acid, or 18 grains of tartaric acid, or by half a fluid ounce of lemon-juice. *Bicarbonate of Potash* ($\text{KO}, \text{HO}, 2\text{CO}_2$) may be used in the same cases as the carbonate or solution of potash. It is chiefly used for the manufacture of effervescing draughts, 20 grains of the crystallized salt being neutralized by 14 of citric acid, 15 of tartaric acid, and $\frac{3}{4}$ drachms of lemon-juice. *Chlorate of Potash* (KO, ClO_3) is prescribed with advantage in diseases of a low type, such as scarlatina maligna, cancrum oris, diphtheria, scurvy, &c. As it is eliminated unchanged by the kidneys, its *modus operandi* is unknown. It may be prescribed in doses of from ten to twenty grains three times a day in a solution. *Citrate of Potash* ($3\text{KO}, \text{C}_3\text{H}_3\text{O}_7$) is obtained by neutralizing a solution of citric acid with carbonate of potash, filtering and evaporating to dryness, when the salt is deposited as a white powder of a saline, feebly acid taste, deliquescent, and very soluble in water. It is procured *ex-tempore* in a state of solution in the effervescing draughts for which we have given prescriptions in our remarks on the carbonates of potash. It acts mildly on the skin, bowels, and kidneys, whose secretions it promotes, and is an excellent cooling diaphoretic in fevers with a hot and dry skin, being less liable to act on the bowels than the tartrate or acetate of potash. In irritability of the stomach, it is an excellent remedy, when given as an effervescing draught. It may be taken in doses of a scruple or half a drachm in solution every few hours. The therapeutic uses of *nitrate of potash* are noticed in the article NITRE. *Sulphate of potash* (KO, SO_4) is useful as a mild laxative, a scruple of this salt, especially if combined with ten grains of rhubarb, usually acting mildly and efficiently. It has considerable power in repressing the secretion of milk, and has been much used for this purpose.

The uses of the *tartrates of potash* are noticed in the article TARTARIC ACID. *Bromide of Potassium* (KBr) occurs in white, transparent, cubical crystals, and is occasionally employed in enlargement of the spleen and in certain forms of epilepsy. The uses of *iodide of potassium* are described in the article IODINE.

POTASH-WATER. See AERATED WATERS.

POTATO (*Solanum tuberosum*; see SOLANUM), one of the most important of cultivated plants, and in universal cultivation in the temperate parts of the globe. It is a perennial, having herbaceous stems, 1–3 feet high, without thorns or prickles; pinnate leaves with two or more pair of leaflets and an odd one, the leaflets entire at the margin; flowers about an inch or an inch and a half in breadth, the wheel-shaped corolla being white or purple, and

more or less veined; followed by globular, purplish fruit, of the size of ordinary gooseberries; the roots producing tubers. The herbage has a slightly narcotic smell, although cattle do not refuse to eat a little of it, and the tender tops are used in some countries like spinach. The tubers are, however, the only valuable part of the plant.

The P. is a native of mountainous districts of tropical and sub-tropical America, probably from Chili to Mexico; but there is difficulty in deciding where it is really indigenous, and where it has spread after being introduced by man. Humboldt doubted if it had ever been found truly wild; but subsequent travelers, of high scientific reputation, express themselves thoroughly satisfied on this point. Except that the tubers are smaller, the wild plant differs little from the cultivated. Maize and the P. are the two greatest gifts which America has given to the rest of the world.

The P. has been cultivated in America, and its tubers used for food, from times long anterior to the discovery of America by Europeans. It seems to have been first brought to Europe by the Spaniards, from the neighborhood of Quito, in the beginning of the 16th c., and spread from Spain into the Netherlands, Burgundy, and Italy, but only to be cultivated in a few gardens as a curiosity, and not for general use as an article of food. It long received throughout almost all European countries the same name with the Batatas (q. v.), or Sweet Potato, which is the plant or tuber meant by English writers down to the middle of the 17th c., in their use of the name potato. It appears to have been brought to Ireland from Virginia by Hawkins, a slave-trader, in 1565; and to England by Sir Francis Drake, in 1585, without attracting much notice, till it was a third time imported from America by Sir Walter Raleigh. It was still a long time before it began to be extensively cultivated. Gerard, in his *Herball*, published in 1597, gives a figure of it under the name of *Batata Virginiana*; but so little were its merits appreciated, that it is not even mentioned in the *Complete Gardener* of London and Wise, published more than a century later, in 1719; whilst another writer of the same time says it is inferior to skirret and radish! It began, however, to be imagined that it might be used with advantage for feeding 'swine or other cattle,' and by and by that it might be useful for poor people, and for the prevention of famine on failures of the grain-crops. The Royal Society took up this idea, and in 1663, adopted measures for extending the cultivation of the P., in order to the prevention of famines. To this the example of Ireland in some measure led, the P. having already come into cultivation there, to an extent far greater than in any other European country, and with evident advantage to the people.

From Ireland, the cultivation of the P. was introduced into Lancashire about the end of the 17th c., soon became general there, and thence spread over England; so that, before the middle of the 18th c., it had become important as a field-crop, which it became in the south of Scotland some 20 or 30 years later; about the same time, in Saxony and some other parts of Germany; but not until the latter part of the century, in some other parts of Germany and in France. In France, the extension of P. culture was very much due to the exertions of Parmentier. In some parts of Germany, the governments took an interest in it, and promoted it by compulsory regulations.

The P. is of great importance as affording food both for human beings and for cattle; and next to the principal cereals, is the most valuable of all plants for human food. It is also used for various purposes in the arts. No food-plant is more widely diffused; it is cultivated in sub-tropical countries; and struggles for existence in gardens, even within the arctic circle, yielding small and watery tubers; although the effects of late spring frosts, or early autumnal frosts, upon its foliage, often prove that it is a plant properly belonging to a climate milder than that of most parts of Britain. No more important event of its kind has ever taken place than the general introduction of P. culture into the husbandry of Britain and other European countries. It has exercised a most beneficial influence on the general welfare of the people, increasing national wealth, and preventing, as a few far-seeing thinkers had anticipated, the once-frequent returns of famine. That in 1846 and 1847, terrible famine resulted in Ireland and elsewhere from the failure of the P. crop itself, was owing only to the excess to which its cultivation had been carried. The results confirmed two great laws, that plants long very extensively or almost exclusively cultivated in any district, however successfully they may be cultivated for a time, are sure to fail at last; and that the exclusive, or almost exclusive dependence of a people on one source or means of support, is unfavorable to their welfare in respect to all their interests.

Humboldt calculates that the same extent of ground which would produce thirty pounds of wheat, would produce one thousand pounds of potatoes. But potatoes are not nearly so nutritious as wheat, and the constant employment of them as the chief article of food, is not favorable to the development of the physical powers, and is consequently in its protracted influence

unfavorable to mental energy. All this is too well illustrated in Ireland and the Highlands of Scotland, in a race capable of the highest development of both. It is calculated that 100 parts of good wheat-flour, or 107 parts of the grain, contain as much actual nutriment as 613 parts of potatoes. The inferiority of the P. in nutritious power is very much owing to the comparatively small quantity of nitrogenous substances which it contains, in consequence of which it is most advantageously used along with some very nitrogenous article of food, in Britain generally with animal food, in some parts of Europe with curds or with cheese. The P. tuber, in a fresh state, contains about 71–80 per cent. of water; 15–20 of starch, 3–7 of fibre or woody matter, 3–4 of gum, dextrine and sugar, and 2 of albumen, gluten, and casein. There are considerable differences, however, in different varieties, in different stages of maturity, and in different soils and seasons.

Potatoes are used, both raw and boiled, for the feeding of cattle. For human food, they are variously prepared by roasting or boiling, but now chiefly by boiling, a process by which they are freed from all that is narcotic and noxious in their juice. The water in which potatoes have been boiled is not wholesome, and those modes of preparing them for the table which do not admit of its complete rejection, ought to be avoided.

The herbage or haulm of the P. has been used for making paper, but the results were not encouraging. The berries are sweetish, but not pleasant; nauseous when fermented, but yield by distillation a tolerable spirit.

The varieties of the P. in cultivation are extremely numerous. Any enumeration or classification of them is impossible. New ones are continually appearing, and old ones passing away. Those most advantageously cultivated in particular soils and climates, are often found to degenerate when removed to a small distance. Many of the new varieties of P. are raised in Lancashire, but particularly of the garden kinds, which generally differ from those preferred for field-culture in their greater earliness, and not unfrequently in their inferior productiveness, and in their being less *mealy* and less nutritious. Potatoes differ considerably in the character of their herbage—which is sometimes erect, sometimes straggling—and in the size and color of their flowers; but are more generally distinguished by the size, form, and color of their tubers, which are round, long, or kidney-shaped, white, red, dark purple, variegated, &c.

New varieties of P. are produced from seed; but potatoes are ordinarily propagated by planting the tubers, or cuttings of the tubers, each containing an *eye* or bud. Late crops of early potatoes are sometimes procured by cuttings of the stalks or by layers; methods which might probably be pursued with more advantage where the summer is longer than in Britain. Much has been written by gardeners and agriculturists on the comparative advantages of planting whole tubers or cuttings; but the latter method generally prevails.

Potatoes are planted in drills, made either by the spade or plough; or in *lazy beds*, which are always made by the spade, and are beds in which the sets of potatoes are covered over with earth dug out of the alleys. The alleys serve, although imperfectly, for drains in undrained land. The cultivation of potatoes as a field-crop seems to have been first attempted in lazy beds. They are still common in many parts of Ireland, but are now rare in most parts of England and Scotland. They are very suitable for strong, heavy, and somewhat moist land, and are profitably used in reducing some kinds of soil to cultivation, but are generally unsuitable for field-culture, owing to the expense of labor required. In strong heavy land, potatoes are cultivated in raised drills; in lighter and drier soils, the raising of the drills is unnecessary. Manure is generally given, consisting generally of dung and well-rotted straw from the farm-yard. Guano and other strong artificial manures are apt to produce an excessive growth of stalks and leaves, which is to be guarded against by diminishing or even withholding manure in certain soils; potatoes of too luxuriant growth being always particularly liable to diseases. The cultivation of potatoes, after they are planted, whether in the field or garden, consists chiefly in keeping the ground clear of weeds, and in earthing up the plants, to promote the formation of tubers. Potatoes are taken up either by the fork or by turning over the drills with the plough. Garden potatoes are generally used long before they are really ripe, forming a favorite dish in a very unripe state, when they are far from being a safe article of food, and contribute not a little to the prevalence of cholera and kindred diseases in summer.

Field potatoes, unless when intended for the supply of the markets of towns, like garden potatoes, are allowed to ripen thoroughly, and are then capable of being stored for winter and spring use. Early potatoes are forced in hot-beds, and in the spare ground of hothouses, that they may be obtained very early; also, after being thus brought forward in some degree, they are planted out in gardens, for a succession of young tubers. The planting of potatoes in the open air cannot be successfully practiced in most parts of Britain before February or March, and in

many seasons the later-planted are found as early as the earlier-planted, and more productive. The storing of potatoes is variously accomplished in dry lofts or sheds, in airy cellars or barns, and in *pits*, which are sometimes holes excavated to a small depth in the earth, and the potatoes piled up above the surface of the ground, in a conical, or in a roof-like form, sometimes mere heaps of one or other of these forms upon the surface of the ground, and covered with straw and earth to keep out light and frost. The access of light makes potatoes green, bitter, and unwholesome, as is often seen in those which, whilst growing, have been partially above ground. P. pits are often ventilated by means of pipes, as without ventilation the potatoes are apt to heat and sprout. Potatoes taken from the ground before they are quite ripe are extremely apt to heat and sprout.

The P. crop is now an important one in almost all the rotations practised in Britain, although its cultivation is in most districts not quite so extensive as before its failure from the *P. disease* in 1845 and subsequent years, and farmers are more careful not to depend too much upon it. It very commonly succeeds a grain-crop, but sometimes is advantageously planted on land newly broken up from grass.

The P. is subject to a number of diseases, of which the most important is the *P. Disease* (q. v.) or *P. Murrain*. Before it began to prevail, the chief diseases affecting the P. were those called *Curl*, *Scab*, *Dry Rot*, and *Wet Rot*. Of all these diseases, it would seem that one principal cause, however combined with other causes, is the exhaustion of the vegetative powers of the plant, from frequent propagation by tubers or cuttings of tubers. It is to be borne in mind that propagation by tubers is not properly reproduction, but one plant is divided into a multitude; and the whole analogy of nature seems to show, that although it may live longer in this way and more healthfully than if left to the spot where its seed first germinated, its existence will come to an end, and the species must be preserved by reproduction from seed. It was long since observed as to *CURL*, the dread of farmers and gardeners before the *P. disease* was known, that it most readily attacks potatoes which sprung from weak sets. *Curl* is a disease affecting the foliage and general health of the P. plant, and does not seem to be necessarily connected with the presence of any vegetable parasite or insect enemy.—*SCAB* is a disease of the tubers, which become covered with brown, oblong, and finally confluent and cup-shaped spots, whilst under the surface is a powdering of minute olive-yellow grains, a fungus called *Tubercinia Scabiei*, of the division *Hyphomycetes*.—*DRY ROT* is also ascribed to the growth of a fungus of the same order, *Fusisporium Solani*, and attacks the tubers either when stored for winter or after being planted. It was very carefully investigated by Martius, and described in a memoir published in 1842. It was first observed in Germany in 1830, and caused great loss in that country throughout many years.

The tissues of the P. tuber become hardened and completely filled with the mycelium of the fungus, which at last bursts forth in little cushion-shaped tufts loaded with fructification.—*WET ROT* differs from *Dry Rot* in the tubers becoming soft and rotten instead of hard and dry, and is always characterized by the presence of a fungus referred by Fries to his genus *Periola*, but which Berkeley regards as another form or stage of the same fungus which causes or is inseparably connected with *Dry Rot*. Both *Dry Rot* and *Wet Rot* have often been observed along with the *P. disease*, which, however, is always characterized by the presence of another peculiar fungus.

But, besides its value as a culinary vegetable, the P. is important in other respects. Its starch is very easily separated, and is in large proportions; hence it is cheaper than any other kind. It is manufactured on a very large scale both in this country and on the continent. It is chiefly used in textile manufactories under the name of *farina*, which is converted into dextrine or British gum. See *STARCH*. In Holland and in Russia, where there is much difficulty in keeping potatoes through the winter, and there is consequently a necessity for using the crop quickly, large quantities of starch are made, and this is converted into sugar or syrup. See *SUGAR*. The refuse of the starch-manufactories is all economized; it is pressed out from the water, and either used for pig-feeding or for manure. In the north of Europe, much spirit for drinking is made from potatoes; it is called *Potato Brandy*.

POTA'TO-BEETLE. See *COLORADO-BEETLE*.

POTATO DISEASE, or POTATO MURRAIN. No subject connected with Agriculture or with Botany has given rise within so short a time to so extensive a literature as this. It has been treated in books and pamphlets, and in magazines and periodicals of every kind. The terrible famines caused by the failure of the potato crop in Ireland and other countries, particularly in 1846 and 1847, concentrated upon it the attention of the whole civilized world; and yet it remains very obscure.

The potato disease seems to have been at first confounded with *Dry Rot* and *Wet Rot* (see *POTATO*), which appeared a

number of years before it to a formidable extent, although not to be compared with it in their ravages. This fact—and all the more if the potato disease is to be ascribed to the presence of a different and peculiar fungus—may perhaps be held as giving support to the opinion that its chief cause was really the weakening of the plant through too constant cultivation on the same land, and continued propagation by tubers alone.

The potato disease was first observed in Germany, and first assumed a very serious character near Liège in 1842. In 1844 it broke out in Canada, and all at once proved very destructive. In 1845, it was first noticed in England, and first in the Isle of Wight. But during that year, its ravages were considerable in the British Islands; much more so in the year following, when the Irish famine was the consequence, and in the same year it prevailed very extensively over almost all parts of Europe. The summer was unusually cloudy and moist, a circumstance probably not without its effect. In 1847, the disease was still prevalent but to a smaller extent; and since that time its prevalence has gradually diminished, although it occasionally breaks out in particular localities. Meanwhile, it is to be observed, that almost all the varieties of potato cultivated to any considerable extent before 1846, have disappeared, and been replaced by others. Last too much, however, should be inferred from this in favor of a particular theory, it must also be stated, that potatoes newly raised from seed were sometimes severely attacked by the disease during the period of its greatest prevalence.

No fully satisfactory theory as to its cause or origin has been proposed. That it has long existed in the western parts of America, may probably be true, as has been alleged, although the distinction between it and other diseases of the potato might not perhaps be noted with sufficient care; but even this would not account for its sudden appearance and terrible devastations in other parts of the world. Many observers ascribed it to insects and *acari*, some even to infusoria in the tissues, but the presence of none of these was found to be constant, and they appeared therefore rather to be the consequences than the cause of the disease. It is otherwise with the fungus, *Botrytis infestans* (see *BOTRYTIS*), which is always present, although probably, like other parasites, it generally attacks an already weakened plant. The disease generally first appears in the leaves, and thence extends to the tubers, although it has been sometimes observed to appear in the tubers of some of the early kinds of which the leaves have perished before the season when it breaks out. It sometimes also lies dormant in the tubers for months, so that after being stored apparently sound in autumn, they become diseased in the following spring. When the disease appears in the growing plant, brown spots are first to be noticed on the margins of the leaves, corrugating the leaves as they spread. Very rapid extension of the disease, and decay of the leaves and stalks often ensue. It is on the under surface of the leaf that the *Botrytis* is found; it abounds also in the diseased tubers, which, when cut, produce an abundant crop of it from the fresh surface, and it sometimes vegetates even from the natural surface. The same fungus has been found in the berries of the Tomato (q.v.) when diseased, and on the leaves of other plants of the natural order *Solanaceæ*, but never on any plant not of that order. See *COLORADO BEETLE*.

The starch granules which exist within the cells of potatoes seem not to be affected by the potato disease, but remain unaltered in quality, so that as good potato starch is made from unsound as from sound tubers. On occasion of the great ravages of the disease in 1846, however, advantage was but partially taken of this fact, partly from ignorance of it; partly from an apprehension, apparently quite unfounded, that the starch might prove unwholesome; and partly from the want of machinery to grate down the diseased potatoes before rotteness had involved the whole.

POTATO-FLY (*Anthomyia tuberosa*), a dipterous insect of the

Potato-fly.

1, Larva or maggot, natural size; 2, larva magnified; 3, Potato-fly.

same genus with the Beet-fly, Cabbage-fly, Turnip-fly, &c. In its perfect state, it is very like the House-fly. The male is about five lines long, grayish-black, bristly, with five indistinct broad

stripes on the back, and four ochreous spots on the second and third segments; the female ashy-slate color, with two indistinct ochreous spots on the second abdominal segment. The maggots are very abundant in bad potatoes in autumn, and are very different from the maggots of the House-fly, being horny, spiny, bristly, and tawny; the long tail ending in six long bristles. The pupa is very like the larva.

POTCHEFSTROOM, or **POTSCHERFSTROOM**, a town in the Transvaal, South Africa, on the Mooi River, and about 25 miles north of the Vaal River. A British garrison at P. surrendered to the Boers in 1881. Pop. 8900.

POTCHINKY, a town of Russia, in the government of Nijni-Novgorod, 800 miles south-east from St. Petersburg. Pop. (1880) 7224.

POTEMKIN, **GREGORY ALEXANDROVITCH**, the most celebrated of the Czarina Catharine II.'s favorites, was born near Smolensk in September 1736. He was descended of a noble Polish family, and at an early age entered the Russian army, and rose to be ensign in the imperial horse-guards. Happening to attract the notice of the czarina by his noble appearance and handsome athletic figure, he was forthwith (1762) attached to her household, and appointed colonel and gentleman of the bed-chamber. After a time (1774), he superseded Gregory Orlov (q.v.) in the good graces of the czarina, and became her favorite and avowed lover. He played the part of lover for only two years, when he was superseded by a younger and more amiable successor; but the ascendancy which he had acquired over the czarina was in nowise affected by this change. He knew well how to flatter her vanity, rouse her fears, and make her believe that he alone could protect her from the numerous conspiracies (some of which were real, and many mythical) which were being constantly formed against her. Catharine submitted to all his caprices, consulted him in everything, and was in almost all cases guided by his advice. P. was consequently, from 1770 till the year of his death, the true representative of the Russian policy in Europe; and Frederick the Great of Prussia, and even the haughty Hapsburgs, Maria Theresa and Joseph II., cringed at his feet, and, at the demand of the czarina, loaded him with titles and honors; though, much to his chagrin, he failed to obtain the English order of the Garter, and the French one of the Holy Spirit.

P. interfered little with the internal government of Russia, beyond offering many valuable suggestions for the development of manufactures and industry, which were carried out; his important achievements being connected with the foreign policy of Russia, especially as far as it related to Turkey. It was at his instigation that the Turks were forced into war, and robbed of their territories north and east of the Black Sea, in order that Russia might possess a southern sea-board; and after this had been done P. immediately ordered the creation of a Black Sea fleet, and the building of Kherson, Kertch, Nikolaiev, and Sebastopol. For his services, he was created governor of the Taurida (q.v.), and loaded with numerous honors and presents. In 1787, Catharine paid a visit to him at his government, and the 'hoax' which he played off on his sovereign is well described by De Segur. He caused an immense number of wooden painted houses to be constructed, and grouped into towns and villages along the route the czarina was to take, and hired people to act the part of villagers, merchants, tradesmen, and agriculturists, engaged in their various pursuits. The czarina's vanity was hugely gratified at the seeming improvements of the country under her rule, and P. was rewarded for his dexterity by further honors and emoluments. Almost immediately after this, a war broke out with the Turks, and P. was placed at the head of the army, with Suwarof and Repnin for his lieutenants. His career was one of uninterrupted victory. Bessarabia and the two principalities were conquered, and he was about to advance on Constantinople, when the empress commanded a cessation of hostilities; but before P. had time to bring her round to his own views, he was seized with sudden illness on the road between Jassy and Nikolaiev, and died there, October 15, 1791.

POT'ENT, CROSS, in Heraldry, a cross crutch-shaped at each extremity. It is also called a Jerusalem cross, from its occurrence in the insignia of the Christian kingdom of Jerusalem, which are, Argent, a cross potent between four crosslets or. This coat is remarkable as being a departure from the usual heraldic rule which prohibits the placing of metal upon metal.

POTENT COUNTER-POTENT, one of the heraldic furs, in which the field is filled with crutch-shaped figures alternately of metal and color, those of opposite tinctures being placed base against base, and point against point. The metal and color are understood to be argent and azure, unless they be specially blazoned otherwise. Potent counter-potent is sometimes blazoned Vairy-cuppy.

POTENTÉE, a heraldic line of division which takes the form of the outline of a succession of crutch shaped figures.

POTENTILLA, a genus of plants of the natural order *Rosaceae*, suborder *Potentilleae*, differing from *Fragaria* (Strawberry) in the fruit having a dry instead of a succulent receptacle. The species are very numerous, natives chiefly of northern temperate regions, and some of them of the coldest north; most of them perennial herbaceous plants, with yellow, white, red, or purple flowers, and pinnate, digitate, or ternate leaves. They are often called **CINQUEFOIL** (Fr. five-leaved); and some of the species are favorite garden flowers. A few are natives of Britain; one of the rarest of which is a shrubby species (*P. fruticosa*), forming a large bush, with pinnate leaves, and a profusion of yellow flowers, often planted in shrubberies.

P. reptans, a common British species, with creeping stems, digitate leaves, and yellow flowers, once had a high reputation as a remedy for diarrhoea, from the astringent property of its root, of which most of the species partake with it. But *P. anserina*, a very common British species, popularly known as **SILVERWEED**, having creeping stems, yellow flowers, and pinnate leaves, which are beautifully silky and silvery beneath, has an edible root, with a taste somewhat like that of the parsnip. Swine grub it up with avidity, and it was once much esteemed as an article of food in some parts of Scotland, particularly in the Hebrides, where it abounds and has been a resource in times of famine.—The name *P.* is said to be derived from the Latin *potens*, powerful, and to allude to medicinal virtues now known to merit little regard. *Tormentil* (q. v.) is sometimes referred to this genus.

POTE'NZIA (anc. *Potentia*), in South Italy, the chief town of the province of Potenza, is situated on a hill of the Apennines, near the river Vaseuto or Basento, 54 miles east of Salerno. Pop. 18,500. It is surrounded by a wall, has a fine cathedral of the Doric order, and is the seat of an archbishop. *P.* was shaken by earthquakes in 1278, 1694, and 1812. The province of *P.*, which as a *compartimento* of the kingdom, is called Basilicata, used to suffer severely from brigandage.

POT-HERBS are not, as might be supposed from the name, the vegetables chiefly used for culinary purposes as supplying articles of food, but rather those which are of secondary importance, and valuable chiefly for flavoring, as parsley, fennel, &c.

POT-METAL is an alloy of lead and copper, obtained by throwing lumps of copper into red-hot melted lead. It is of a gray color, brittle and granular.

POTO'MAC, a river of the United States, formed by two branches, which rise in the Alleghany Mountains, and unite 20 miles south-east of Cumberland, Maryland, from which point the river flows in a generally south-easterly course, 400 miles and falls into Chesapeake Bay, where it is 6 to 8 miles broad, 75 miles from the ocean. Line-of-battle ships ascend to Washington, 120 miles from its mouth, and the tide reaches Georgetown. Between Westport and Washington, 220 miles, it falls 1160 feet. The scenery in this portion of its course is wild and beautiful, especially where it breaks through the Blue Ridge at Harper's Ferry. Its principal affluents are the Shenandoah, Savage, Monacacy, and Aquia Creek. The *P.* forms the greater part of the boundary between Virginia and Maryland. During the war which began in 1861, both Federal and Confederate armies crossed several times the fords of the Upper Potomac, and severe actions were fought upon its banks.

PO'TOROO, or **KANGAROO RAT** (*Hyposiprinnus*), a genus of marsupial quadrupeds, of the family *Macropidae* (see **KANGAROO**), differing from kangaroos chiefly in having distinct canine teeth in the upper jaw. The first pair of incisors in the upper jaw are also longer and larger than the others. The molars decrease in size backwards; and when not worn, present four blunt tubercles. The fore-limbs are proportionally longer, the hinder-limbs less powerful than in the kangaroos. The general form and habits are similar; there is the same sitting on the hind-feet with help of the tail for support, and a somewhat similar hopping, but not nearly an equal power of vigorous leaping. The stomach is large, and divided into two sacs, with several inflations; the food entirely vegetable. There are several species, all of small size, none of them larger than a rabbit, and all natives of Australia, timid and harmless creatures. They are generally clothed with a dense, and sometimes a beautiful fur; but the tail is nearly destitute of hairs, and scaly.

POTO'SI, one of the richest mining-towns of South America, the second town of Bolivia, and capital of a department of the same name, stands in a dreary and barren district, 13,330 feet above sea-level, in lat. 19° 35' S., and long. 65° 25' W., 70 miles south-west of Chuquisaca. It covers a large area, and in 1611, its population was 170,000, but in 1865 it was 25,774, and great part of the town was in ruins. In its center is a large square, around which are ranged the principal public edifices, as the government-house, town-house, cathedral, &c. The mint is a large building, in which the average amount now coined amounts to about 2,000,000 dollars annually. In the central square, an obelisk

in honor of Bolivar was erected in 1825. English and French manufactures are imported; and as the country in the vicinity produces little or nothing, all supplies have to be brought from a distance. The Cerro (sierra) de Potosi, or Silver Mountain, is 15,200 feet high. Its summit is honey-combed with upwards of 5000 mines, and operations are now carried on at a lower level, where the inrush of water, however, often compels the miners to abandon the richest mines. The quantity of silver extracted from the mines of this mountain has amounted in one year to the sum of £330,544,311 sterling. In 1880 the population of *P.* was quoted at 22,580.

POT-POURRI, in French, the name of a mixture of sweet scented materials, chiefly flowers, dried, and usually placed in a vase with a perforated lid, in order that their perfume may be diffused through rooms in which it is placed. The principal ingredients are rose-petals, lavender flowers and stalks, violets, jessamine flowers, woodruff leaves, cloves, orris-root, pimento, musk, sandal-wood raspings, cedar-shavings, &c. But it also signifies a dish of different sorts of viands, and corresponds, in this sense to the *hotch-potch* of Scotland, and the *Olla Podrida* (q. v.) of Spain.

POT-POURRI, in Music, a selection of favorite pieces strung together without much arrangement, so as to form a sort of medley.

PO'TSDAM, a city in the Prussian province of Brandenburg, and, next to Berlin, the handsomest and best built town in Prussia, is situated on an island at the point of junction between the small stream of the Nuthe and the river Havel, 16 miles south-west of Berlin. Population in 1871, 43,784 (with 5475 soldiers); in 1880, 48,447. *P.* is the usual summer residence of the royal family of Prussia, and seat of the imperial court. The city is divided into old town and new town, and has four suburbs. The streets are broad and regularly built, and there are fine squares, some of which are planted with trees, forming pleasant public walks. Of the many large and handsome buildings, one of the most worthy of notice is the old royal palace, an oblong parallelogram, three stories high, with a magnificent colonnade facing the fine Havel Bridge. *P.* has several benevolent and educational institutions connected with the state, as, for instance, two asylums for the orphan children of military men, and one for those of persons belonging to the civil service; schools for cadets, sub-alterns, and privates; the Luisendenkmal, an institution for providing for indigent girls of irreproachable character; a gymnasium, a high-school, and various other training and special schools. Among the churches, the most noteworthy are the Garnisons-kirche, with a tower 400 feet high, a fine chime of bells, and a noble marble pulpit, below which rests the remains of Friedrich Wilhelm I. and Friedrich II., and St. Nicolai's, lately rebuilt after the model of the Pantheon at Paris.

The Brandenburg-Thor, which is the handsomest of the various gates, is a triumphal arch copied from Trajan's Arch at Rome; and this, like the other gates, opens upon a fine allée of trees. *P.* is surrounded with pleasant public walks and gardens, wooded heights, and vine-covered banks; while in the immediate neighborhood are numerous royal country palaces, as Sans-Souci, the favorite residence of Frederick the Great, surrounded by a fine park, pleasure-grounds, and choicely-stocked gardens, near which stands the Ruinenberg, with artificially constructed ruins, designed to conceal the water-works which supply the fountains of the palace. Near the park is the New Palace, begun in 1768, 680 feet in length, containing nearly 100 rooms, many of which are filled with costly works of art. Near Sans-Souci is Charlottenhof, built by the late king, a pleasant villa, with lovely gardens, in which stands a Pompeian house. The Russian colony of Alexandrowska, with its Russian houses and Greek church, lies near the Pfingstberg, which is surmounted with an unfinished palace, from whence a fine view is obtained of the numerous royal parks and gardens, and the surrounding country. In the New Garden stands the Marble Palace, with arcades adorned with frescoes of the *Nibelungen Lied*.

P. is the seat of the provincial government, and of several of the state manufactories. Of these, the most important is the manufactory of arms, at which the rifles for the army are made. There are also numerous private manufactories of machinery, chocolate, tobacco, cotton goods, silk, leather, wax-cloth, beer, &c.

P. owes its creation as a town to the great elector, Friedrich-Wilhelm, who built a royal palace here between 1660 and 1673, and laid out several good streets. Prior to that period, it was an insignificant fishing village, built on the site of an ancient Wendish settlement.

POTSDAM, a township and village in New York, U.S., on Racket River, St. Lawrence County, in the northern portion of the state, between Lakes Ontario and Champlain. There are quarries of sandstone, mills and factories on the falls of the river, a railway connecting it with Watertown, a bank, and six churches. Pop. (1870) 7774.

POTSTONE, *Lapis Ollaris* of the ancient Romans, a variety of Talc (q. v.), or rather a mineral formed by a mixture of talc with chlorite, &c. It is generally of a grayish-green color, sometimes dark green. It occurs massive, or in granular concretions. It is soft and easily cut when newly dug up; greasy to the touch, and infusible even before the blowpipe. It becomes hard after exposure to the air. It is made into pots and other household utensils, which communicate no bad taste to anything contained in them, and when greasy are cleaned by the fire. It was well-known to the ancients; and Pliny describes the manner of making vessels of it. It was anciently procured in abundance in the isle of Siphnos (now Siphanto), one of the Cyclades, and in Upper Egypt. Large quarries of it were wrought on the Lake of Como, from about the beginning of the Christian era, to 25th August 1618, when they fell in, causing the destruction of the neighboring town of Pleurs, in which it was wrought into culinary vessels, slabs for ovens, &c. It is quarried in the Valais, where it is called *Gillstein*; in Norway, Sweden, Greenland, and near Hudson's Bay, &c. 'Should you again visit Italy, and pass by the Great St. Bernard, if the cold of that frigid region should induce you to warm yourself in the refectory of the hospitable monks of the convent, you will there see a stove of poststone.'—*Jackson on Minerals and their Uses*.

POTT, AUG. FRIEDR., a distinguished philologist, was born at Nettelrede in 1802, attended school at Hanover, studied theology and philology at Göttingen (1821), and finally (1833) became professor of the science of language in the university of Halle. Next to W. Humboldt, Bopp, and Grimm, the name of P. stands prominent in the new science of comparative philology. The foundation of his reputation was laid by his *Etymologische Forschungen* (Etymological Researches, 2 vols., Lemgo, 1833—1836), a work second in importance only to Bopp's *Comparative Grammar*. In a well-known article in Ersch and Gruber's *Encyclopædia, Indogermanischer Sprachstamm* (2d sect. vol. 18), he gave a masterly sketch of the Aryan Languages (q. v.). In numerous articles in periodicals, and in separately published treatises (e. g., *De Borussia-Lithuaniæ tam in Slaviciæ quam in Letticiæ Linguæ Principiis*, Halle, 1837—1841; and *Die Zigeuner in Europa und Aisien*, 2 vols. Halle, 1844—1845), he carried his researches into special fields of this great province. *Die Quinary und Vigesimal Zählmethode* (The Quinary and Vigesimal Notation, Halle, 1847), and *Die Personennamen* (Proper Names, Leip. 1853), are admirable treatises, containing an overwhelming mass of information, and showing an astonishing knowledge, not only of the Aryan languages, but of other Asiatic, African, and American races. In 1856 he published a work on the *Difference of Races from a Philological Point of View*, and in 1868 one on the *Diversities of European Languages*.

POTTER, JOHN, D.D., an English scholar and divine, the son of a linen-draper of Wakefield, in Yorkshire, was born in 1674, studied with great diligence and success at Oxford, where he took his degree of M.A. in 1694, and in the same year went into orders. He was appointed chaplain to Queen Anne in 1706, professor of divinity at Oxford in 1708, bishop of Oxford in 1715, and finally in 1737 attained the highest dignity in the English Church—the archbishopric of Canterbury. He died Oct. 21, 1747, and was buried at Croydon. P. was really a superior scholar, but of the dull and plodding sort. Nowhere does he flash a ray of clear searching intelligence on his subject; his habit of mind is quite uncritical, and consequently his learned labors, though creditable to his industry, have added nothing to our knowledge, and have now 'followed' their mediocre author into something very like oblivion. P.'s principal work is his *Archæologia Græca* ('Antiquities of Greece,' 2 vols. 1698), superseded for many years by Dr. W. Smith's *Dictionary of Greek and Roman Antiquities*; besides which, however, we may mention his edition of *Lycophron* (1697), and of *Clemens Alexandrinus* (1715). As a church dignitary, the linen-draper's son is said to have been haughty; he was likewise very 'zealous' in matters ecclesiastical, a vigilant guardian of clerical interests, and strictly, perhaps we may even say excessively, orthodox.

POTTER, PAUL, one of the most distinguished masters of the Dutch school. He was born at Enkhuyzen in 1625, and was the pupil of his father, Pieter Potter, an obscure painter. His progress was so rapid, that by the time he had attained the age of 15, his reputation as an artist was high. He left Amsterdam, and established himself at the Hague, where, in 1650, he was married; in 1652, however, he returned to Amsterdam, at the solicitation of the burgomaster Tulp, who commissioned him to paint a great number of works; but his health, which was delicate, gave way under constant application at his easel, and he died before he had completed his 29th year. Paul P.'s cattle-pieces are perhaps more highly valued than like pictures by any other master.

POTTERIES, THE, a district in Staffordshire nine miles long, including Hanley, Burslem, Fenton, and other places, now incorporated with the parliamentary borough of Stoke-upon-Trent.

The inhabitants of the district are mostly connected with the manufacture of pottery.

POTTER'S CLAY or **FIGULINE**, a kind of Clay (q. v.); either slaty and massive, or more generally, earthy; yellow, yellowish-white, gray, or sometimes greenish; adhering strongly to the tongue, and forming a paste with water. The earthy variety is sometimes very loose, sometimes almost solid. P. C. is a mineral of very common occurrence in alluvial districts, and sometimes occurs in beds of considerable thickness. It occurs in many parts of Britain. It is used in potteries for the manufacture of earthenware; the different varieties of it being adapted to different kinds of earthenware. Houses are built in Egypt of pots of this material.—P. C. is also employed in agriculture for the improvement of light sandy and calcareous soils.

POTTERY. This term—derived, through the French *poterie*, from the Celtic word *pot*, which has passed into Teutonic and Romance tongues—is applied to all objects of baked clay. The invention of pottery dates from the most remote period, and its application is almost universal—objects of pottery being in use amongst races even semi-barbarous. The art of moulding or fashioning vessels of moist clay, and subsequently drying them in the sun, is so obvious, that it is not above the intelligence of the rudest savage. Hence, at the most remote antiquity, the Egyptians, to whom precedence must be assigned in this art, made bricks of unbaked or sun-dried clay, cemented with straw, which were quite sufficient for the purposes of construction in a country where little or no rain falls. These bricks, in shape resembling those in use at the present day, but of larger dimensions, were impressed, at the earliest period, with the marks of the brick-maker, and later, with the names and titles of the kings for whose constructions they were made. The oppression of the Hebrews chiefly consisted in compelling them to work in the brick-fields—a task imposed on captives taken in war and reduced to slavery;

Fig. 1.—Unglazed Egyptian Bottle in the British Museum.

Fig. 2.—Glazed Egyptian Vases in the British Museum.

and the fortresses of Pithon and Rameses, on the Egyptian frontiers, were made of bricks by the Hebrews. Kiln-dried bricks, in fact, did not come into use in Egypt till the Roman dominion, although some exceptional objects of the class of bricks have been found, such as a kind of conical plug, stamped on the base with the names of the tenants of the tombs.

A few other objects were made in unbaked clay; but vases of baked earthenware were in use at the earliest period of Egyptian civilization, and are contemporary with the Pyramids themselves. The Egyptians made a red ware, pale-red or yellow ware, and a lustrous or polished red ware—the two first being used for vases destined for culinary and other purposes, the last for vases of more refined use, such as holding perfumes, wine, honey, and other delicacies. But the most remarkable Egyptian pottery was the so-called porcelain, made of a fine sand or frit loosely fused together, and covered with a thick silicious glaze of a blue, green, white, purple, or yellow color. This celebrated ware, the porcelain of the old world, sometimes exhibits the most beautiful tints of blue, a color which was produced by an oxide of copper, and which is still unrivalled. Objects were made of this material for the decoration of the dead and for the toilet. They were exported from Egypt to the neighboring countries, and are found alike in the tombs of the Greek isles, the sepulchres of Etruria, and the graves of Greece. Most of the figures of deities, the sepulchral ones deposited with the dead, a few elegant vases, portions of inlaying, objects of the toilet, and beads and other decorations, are made of this porcelain. Still finer work of this kind was produced by carving scarabæi and other small objects in steatite, and covering them with a blue glaze, so as to combine brilliancy of color with delicacy of execution. The Egyptians had at the earliest period the simpler manipulations and tools of pottery—the potter's lathe or wheel, moulds for stamping objects, and various other tools. On the decadence of the country, under the Greeks and Romans, the pottery became assimilated to the Greek and Roman.

In the contemporary empires of Assyria and Babylon, pottery was also in use at an early period. Sun-dried and kiln-dried

bricks were made in the reigns of Uruk and other monarchs of the oldest Babylonian dynasties about 2000 B.C. Platforms for elevating the larger edifices were made of them; and the bricks, like the Egyptian, were stamped with the names and titles of the monarch, to which was added the locality for which they were destined. Glazed bricks of various colors, occasionally enriched with scenes and ornamental designs, were introduced into constructions; and Semiramis is said to have adorned with them the walls of Babylon. The Assyrians and Babylonians employed this material for historical and legal purposes, making cylinders, hexagonal prisms, and purse-shaped objects of it, on which were impressed extensive writings. One of these remarkable objects contains the account of the campaign of Sennacherib against Judea and the tributes of Hezekiah. The Assyrian and Babylonian pottery resembles, but is not entirely the same as the Egyptian, being of a pale red ware, of thinner substance, finer paste, and more refined shape. At a later period, figures of deities were modelled in terra cotta. The glazed ware of Babylon and Assyria is coarser than the finest Egyptian, and is the earliest example of the employment of materials for coloring like those now in use; the glaze, however, is silicious. The objects most remarkable for size are the large coffins found at Warka, supposed by some to be the Ur of the Chaldees, with oval covers, and ornaments of the Sassanian period. The potteries of Mesopotamia continued to flourish under the Parthian and Sassanian monarchs till the conquest of Asia by the Mohammedans.

The potter's art is mentioned in the Scriptures, but few specimens of Hebrew wares have been found. Some vases have been exhumed in Phœnicia. The most remarkable pottery of antiquity was the Greek, which seems to have had another origin than the oriental. The terms *keramos* and *ostrakon* were applied by some to this material, and they made objects and vases in sun-dried clay, terra cotta, and glazed ware. The use of bricks was by no means extensive in Greece, although some public edifices were made of them. Their first use is attributed to Hyperbius of Crete, and Euryalus or Agrolas. The bricks were made by a mould (*plasion*) and were called after the numbers of palms-length. Some were so light that they floated on water. Besides bricks, tiles, cornices, artificial ornaments, friezes, pipes for conducting water, and drains, were moulded in terra cotta. Statues and small figures, *pelanoi*, gaily and appropriately painted, covered

Fig. 3.—Greek Vases of various styles.
From the British Museum.

with a *leucoma*, or white ground, and occasionally partly gilded, were in common use for votive and other purposes, and sold at a cheap price by the figurist (*kyroplathos*). Dolls, cones, and various smaller objects were made by the potters; they were sometimes modelled, but more generally moulded. The Greeks claimed the invention of the potter's wheel; and the principal cities contested the honor of the art, which is mentioned in Homer, and attributed to Corebus of Athens, Hyerbius of Corinth, or Talos, the nephew of Dædalus. Numerous vases for all the ordinary purposes of life were made by it, and others of large form, decorated also by separate ornaments, *emblemata*, attached to them. Large casks or *pithei* were modelled on a framework of wood.

Great quantities of amphoræ, manufactured on the wheel, and used to contain the choice wines of Greece, were exported from Rhodes and other cities; and their débris are found in the Crimea, Alexandria, Sicily, and other cities. Some of the earlier specimens of a glazed earthenware were painted with colors in fresco or encaustic, from which afterwards came the more elaborate pictures of the glazed vases of Greece. To these succeeded two or three classes of painted ware, consisting of rude representations of animals laid upon the pale red ground of the clay in brown outlines, a style prevalent at Athens and Asia Minor; which was followed by the potteries of Corinth, or the so-called Phœnician or Egyptian style. The paste of the vases is of a light red or yellow, the figures in a black or maroon color, with portions enriched with crimson or purple; the backgrounds of a pale straw or lemon color; the animals, of a larger size than those of the Athenian vases, intermingled with chimæras and other monsters; the back-

grounds variegated with flowers—the whole derived from oriental art. Gradually, human figures, with all the characteristics of archaic Greek art, were introduced, with accompanying inscriptions, which cannot be later than the 6th or 5th c. B.C. The subjects of these vases were derived from the oldest Greek myths. The style of this pottery by degrees improved: the paste became pale red or salmon color; the human figures, which had been at first subordinate, replaced the friezes of animal and large ornaments. As the improvement went on, the backgrounds were made of a bright orange-red color, the figures of a deep black; while portions, as the hair, garments, and flesh of female figures, were colored white. The style of art became much freer, although still retaining the rigidity of the Ægean school.

Names of figures represented, of the artists who painted and the potters who made the wares, were added, with speeches, and the names of celebrated beauties and athletes of the day. In these styles, the vases made on the wheel appear, while yet soft, to have had the subjects traced upon them with a finely-pointed tool; the figures were then filled in with a lucid black pigment of manganese, and then returned to the furnace. The details of the muscles and other portions were incised through the black with a sharp tool, so as to show the lighter background, and the purples, crimsons, blues, and other colors were laid on. The subjects were chiefly derived from the war of Troy and the heroic age; and the shapes in use were oil-jars (*lecythoi*), water-pails (*hydriæ*), wine-vases (*crateres*), wine-jugs (*anchoæ*), and *amphoræ*. They seem to have continued in use till about 450 or 420 B.C., when the red figures were substituted for black, by tracing, as before, the figures on the clay, then running round them a thick line of flock, and finally filling up the background entirely with black color—the muscles and inner marking not being incised, but traced in black and brown outlines. The earlier vases of this class, which are of the strong style, resemble those of the black figures; but the style gradually improved, and resembled the art of Phidias and Zeuxis; while the letters are those in use after the archonship of Euclid, 403 B.C. The style and form of these vases altered according to the art of the period, till the ultimate disuse of fictile or painted ware, about 300 B.C., when the conquests of Alexander the Great and the increase of luxury caused it to be superseded by vases in metals. In its last stage, the pottery became moulded, and was glazed entirely black, or else variegated with opaque white figures and ornaments.

The subjects of these later vases differ considerably from the earlier, being chiefly derived from the theater or myths of the later poets. Vases of this description are found in Greece, the isles of the Archipelago, and Italy; into which latter country they appear to have been imported from Greece.

In Italy, indeed, the Etruscans, at an early period, and perhaps some of the principal cities in Magna Græcia, manufactured their own pottery. That of the Etruscans consists principally of three kinds—an unglazed red ware; a lustrous brown ware, made also by the neighboring Sabines and Oscans; and a black ware, the paste or substance of which is black throughout, not superficial, as amongst the Greeks, and made by mixing some coloring material with the clay. The Etruscan pottery is rarely painted—the black ware never—but it is distinguished by having ornaments in salient and bas-relief modelled or moulded on it, and by the shapes of the vases apparently being derived from works in metal, and reproducing the fantastic combinations of oriental art. This ware, which was in use from 600 to 320 B.C., was the

Fig. 4.—Greek Vases of later style, found in Italy.

source from which subsequently arose the Aretine and Roman pottery. It was ornamented sometimes with incised ornaments; the subjects, however, are generally uninteresting, and it never attained a high position in art. The Etruscans, however, in later times imitated the painted vases of Greece, but their clay is much paler, the drawing coarser, and the shapes less elegant. In terra

cotta statues, they particularly excelled, and supplied the Romans with the figures of their divinities. Even sarcophagi were made of this material.

On the decline of the pottery of the Greeks and Etruscans, a new kind of ware was made at Arezzo, or Arretium, to which has been given the name of Arretine, and which resembled the later ware of the Greeks. It is evidently imitated from works in metal, in all probability from the chased cups of silver and gold which began to come into use in Italy, and was a continuation of the later moulded wares of Greece and Italy. The vases were of a bright red or black color; the paste, uniform in color throughout, but covered with a lustrous silicious glaze. The red color nearly resembles in color and texture a coarse sealing-wax, the

Fig. 5.—Anglo Roman Vase (Castor).

Fig. 6.—Roman Vase

paste is often remarkably fine. The vases, generally of small dimension, were turned on the lathe; the ornaments were moulded separately, and attached to the vase: patterns were produced by the repetition of the same mould, or by placing bas-reliefs from various moulds on the vases. This kind of pottery was first made at Arezzo, but subsequently, or nearly simultaneously, was produced at Capua and Cumæ in the 1st c. A.D. It afterwards extended over all the Roman world, and was made in Gaul and Germany. It was called Samian ware under the republic, and was at first extremely fine, but deteriorated under the last of the twelve Cæsars, and is no longer found under the Antonines; a red

Fig. 7.—Roman Amphoræ.

ware, glazed with red-lead and copper, having been substituted for it. The names of several hundred potters are found stamped upon extant specimens of this ware, and some of them are evidently of Gaulish or British origin. These names are followed by *F. fecit*, or made; *M. manu*, or by the hand of; and *OF. officina*, or establishment. The ware was extensively imported into Britain and the remotest provinces of the empire; and wherever found shows the influence of Roman civilization. Furnaces for it have been found in France and Germany, but not in England.

The other kinds of Roman ware were local, evidently made upon the spots where found, but with inferior ornamentation. Black-ware seems to have succeeded this, and to have been pro-

duced by confining the smoke of the furnace, and throwing it down upon the heated ware. In Britain, varieties of this ware were made at Castor in Northamptonshire, ornamented with bas-relief, laid on by the process of depositing a fluid clay on the wet ware, and moulding it with a tool. The style of art is Gaulish. Other vases of glazed ware were manufactured at Upchurch near Rochester, and at Crockhill in the New Forest. They have only a few ornaments, either stamped or painted in a white pipeclay on the surface. These vases are probably as late as the 3d c. A.D. Later, arose a black-ware, generally bottles or jugs, glazed externally, and with single words, invitations to drinking, painted on them in a white pipeclay. Many varieties of unglazed ware, red, yellow, white, and gray, were extant in the 2d and 3d centuries. The large culinary and other vessels were made of these—such as casks (*dolia*), amphoræ, jugs (*lagenæ*), and mortars (*mortaria*)—the last at Lyon. The Romans made great use of brick-work terra cotta. All over the empire, bricks were made for public and private buildings, and stamped at Rome with the name of the proprietors of the land, the potters, and the consulate of the period, till the middle of the 3d c. A.D. Bricks were also extensively manufactured by the legions, and bear their names and titles. The graves of the soldiery were often constructed of them. At Rome, the last inscribed bricks are those of Theodoric; none so late have been found in Britain or Gaul. Tiles, cornices, roof-ornaments, and gutters were formed of terra cotta, so were the votive figures offered to the gods; but they all disappeared at the invasion of the northern barbarians, although they continued till then to be manufactured by local potteries.

Among the northern nations, especially the Celts and Scandinavians, long prior to the Roman conquests of Gaul and Britain, at the remote age of the Stone and Bronze Periods, large and small vases, perhaps originally employed for domestic, but subsequently for mortuary purposes, are found amongst the cromlechs, the tumuli, and graves of Northern Europe. They are formed of a coarse clay, mixed with small pebbles, and have been feebly baked by surrounding them with hay, dried ferns, or other combustible vegetable matters, which have been burned inside and around them. The interior of the walls are black; the exterior, of a pale brown color. Their mouths are large, the ornaments, hatchings, and rude line sometimes making an elaborate pattern or tattooing all over the vase. Those from Britain were called *bascauda*, or baskets, by the Romans. A modification of this class of ware was continued under the Saxons and Merovingians, and is distinct from the Gallo-Roman and Romano-British potteries: the clay being better baked, and the ornaments, stamped or impressed from a mould, more regular. The use of pottery among these races was to a great extent superseded by glass, metal, and other substances for drinking and culinary vessels, and few or no specimens of mediæval unglazed vessels are known. Terra cotta, indeed, continued to be applied for making figures from the 14th to the 18th c. in Europe; but in England, even the use of bricks, a manufacture difficult to have been lost, was restored by Alfred.

Unglazed ware was, in fact, superseded or abandoned in Europe after the fall of the Roman empire; but in modern times, the use of terra cotta and such like ware is found extended all over Europe, Asia, and Africa, varying in texture and excellence from the coarse flower-pots to the thin and graceful water-bottles of the Arabs and modern Egyptians. Even the Nigritic races continue to manufacture a feebly baked earthenware, rudely colored with pigments not baked on the ware. In the New World, the existence of unglazed earthenware seems to date from the most remote antiquity. The vases and other objects found in the northern portions of America, indeed, are of the rudest kind, and bear a striking resemblance to those of the early Scandinavian, Celtic, and Teutonic graves, in paste, shape, and ornamentation. The Mexican and Peruvian potteries, however, evince a much greater mastery of the art, and both are modelled with great spirit, gaily colored, and profusely ornamented. Some of the oldest Peruvian wares, indeed, rival in their modelling European art; but they never attain to glazing. The other unglazed wares of the New World differ according to the localities where they have been manufactured, and in the most highly-civilized portions, reflect or rival the arts of the people by which it has been colonized. Those of the existing native races are very feeble, and the processes are sometimes accompanied by magic ceremonies. The pottery of the southern hemisphere is quite recent, as none of the races seem to have been acquainted with the art. The Fijis, indeed, have a ware glazed with the resin of a tree, but it appears to have been derived from Europe.

The knowledge of glazes originally acquired by the Egyptians and Assyrians, was continued under the Roman empire at Alexandria, and appears to have been transmitted to the Persians, Moors, and Arabs. Fayences, and enamelled bricks and plaques, were in use among them in the 12th c., and among the Hindus in the 14th c. A.D. The Moors introduced into Spain the use of glazed tiles about 711 A.D., examples of which, called *Azulejos*, as old as the 13th c., are found in the Alhambra. Besides these, the manufacture of glazed or enamelled fayences in Spain, distinguished by a metallic iridescence, came into use from the 18th c. in Spain. In Italy, they are supposed to have been introduced as early as the conquest of Majorca by the Pisans, 1115 A.D.; but

duced by confining the smoke of the furnace, and throwing it down upon the heated ware. In Britain, varieties of this ware were made at Castor in Northamptonshire, ornamented with bas-relief, laid on by the process of depositing a fluid clay on the wet ware, and moulding it with a tool. The style of art is Gaulish.

the first appearance of Italian enamelled fayence, the precursor of modern porcelain, does not date earlier than about 1420, when it was used for subjects in relief by Lucca della Robbia. About a century later, plates and other ware were manufactured at Pisaro and Gubbio, decorated with subjects derived from the compositions of Raphael and Marc Antonio, painted in gay and brilliant colors. But the establishment was abandoned in 1574, although pieces of *majolica* continued to be fabricated in various cities of Italy till the 18th century. From Italy, this enamelled ware passed into France in 1590 with Catharine de' Medici, where it was manufactured till the end of the 17th century.

In 1555, the celebrated Palissy discovered at Saintes the art of glazing or enamelling a gray paste, and introduced dishes and other objects with fruit, fish, and animals moulded from life, dis-

Fig. 10.—Vase of Henry II. ware.

tributed over the surface, as a kind of ornamental ware. At the same time, or earlier, was made what is called Henry II. ware, and which is now so precious, consisting of glazed white ornamental pieces. Glazed or Norman tiles, however, as they are called, date from two centuries before. At the close of the 13th c., glazed ware was made in Alsace; but it was not till two centuries later that *majolica* was fabricated at Nuremberg; and the manufacture was continued in various parts of Germany till the 18th century. Delft, which gave its name to its own fabric, is said to have produced a glazed ware as early as 1360, and continued to do so till the 19th century.

Holland was chiefly celebrated for its bottles of stoneware, glazed by salt, called *Bellarmines*, *Graybeards*, or *Bonifaces*, and for its tankards, which were imported all over Europe, in the 16th c., and are repeatedly found in London excavations. In England, glazed tiles for religious purposes were made by the monastic or-

Fig. 11.—Tyg with two handles, 14th century.

Fig. 12.—Tyg of Staffordshire ware.

ders from the 12th to the 16th centuries; and glazed bottles, jugs, and cups are found of the time of Henry II.; while Edward III. favored the establishment of potteries in England. The English wares, however, were superseded by Delft and Dutch stonewares till the close of the 17th c., when the coarse wares made at Burslem were improved by the discovery of salt and other glazes. Some Germans, named Elers, from Nuremberg, settled there, and produced an improved ware called the red Japanese; but finding that the secret was discovered by Astbury, left for Lambeth, where they established themselves in 1710.

From this period, various improvements were introduced by

Astbury, Booth, and finally by Wedgwood, who discovered more suitable clays in 1759, and called to his assistance the arts of design, by the employment of Flaxman for bas-reliefs and figures. The applications of copper-plate printing and gliding were subsequently discovered. Still later, other materials, as felspar and bones, were used in the composition of this pottery. Delft-stone and other wares were made at different places, as Liverpool, Lowestoft, and elsewhere; but after different vicissitudes, most of the potteries have disappeared except those of the stoneware at Lambeth and Vauxhall.

None of this ware, however, was of the nature of the Chinese porcelain which had been imported by the Arabs in the 13th c., was known in Italy in 1380, and was imported into France as early as 1370, and into England much later. The name porcelain, from *porcellana*, an obscure Portuguese word, supposed to mean a shell, is applied to a mixture of alumina or *kaolin* and *silice* or *petuntse*, which, when baked, does not fuse at a temperature as high as 140° of Wedgwood's pyrometer, and the glaze of which is incapable of being scratched by a knife. This porcelain, called 'hard porcelain,' is said to have been invented at Siu-ping in China, about 185 B.C., and rose to great importance at King-te-chin, 557 A.D., where, in 1712, 3000 furnaces were in activity, and where the manufacture is still carried on. There are about 18 renowned potteries in the empire. The art of pottery in China is said to be as old as 2599 B.C. In Japan, hard porcelain dates from 27 B.C.; translucent porcelain was made about 672 A.D.; but between 1211 and 1221, Kotosiro, a Japanese potter, went to China to improve his process. There are 18 celebrated potteries in Japan; and in modern times, the pieces exported come chiefly from Inali, in the province of Fizen. In 1644, the Dutch exported 44,943 pieces from Japan. At the beginning of the 16th c., the porcelain of China began to be extensively imported into Europe, and various unsuccessful attempts were made to discover the secret of its manufacture, but without success, both as to the material and the process. The Persians, indeed, are said to have produced translucent pottery about the 15th c. A.D.

After some trials, which resulted either in the production of a kind of opaque glass or stoneware, Böttcher or Böttger, an alchemist (who had been seized by Frederick Augustus II. in 1701), after Schnorr, in 1709, had discovered white *kaolin* at Aue, produced from it a white hard porcelain at Meissen, near Dresden; and the porcelain establishment there was founded under royal auspices. Extraordinary precautions were taken to prevent the process being discovered, by imposing oaths upon the workmen, and the process there pursued was not communicated till 1812 to Brongniart. The secret, however, was betrayed by Stöfzel, a workman of Meissen, who fled to Vienna in 1720, where an imperial establishment was founded, which exists to this day. Other workmen carried the secret from these establishments all over Germany. Royal works were set up at Berlin in 1755, at St. Petersburg in 1744, and at Munich in 1758. From this period, two different kinds of porcelain were made in Europe, a soft and a hard. In France, soft porcelain was made at St. Cloud in 1695, and was not discontinued till 1804. The accidental discovery, by Madame Darnet, of *kaolin* at St. Yrieix la Perche, in 1765, led to the production of hard porcelain at Sèvres, where, after 1800, only this kind was made. Various places in France made both kinds; and in Italy, both were produced at La Doccia, near Florence, at Capo di Monte, near Naples, and at Venice. Other establishments flourished at Madrid and Oporto, established in the 18th century. The manufacture of soft porcelain appears to have been introduced in England, at Bow, as early as the 17th c., and the Chelsea works were set up still earlier, according to some, by Elers. Thence the art was transferred to Derby in 1748; and an establishment at Worcester, founded in 1751 by Dr. Wall, is said to have first printed on porcelain.

Hard porcelain was made by Cookworthy at Plymouth in 1705, and afterwards at Bristol, but was subsequently abandoned as unprofitable, although again made by Minton in Staffordshire in 1850. One of the last inventions in porcelain has been the introduction of Parian, or statuary, used for the production of small figures and statues, by Copeland and Minton. Amongst the oriental nations, the production of porcelain seems limited to China and Japan, although fayences and glazed wares are manufactured

Fig. 13—Staffordshire Minton.

all over the East. The production of a white porcelain, either soft or hard, capable of being moulded and painted with various colors, effected a revolution in the ceramic art: sculptors were employed to mould small figures and other objects by the different establishments, and the vases, which at first were decorated with rude copies or poor imitations of their Chinese originals, by degrees introduced on their surfaces the art of the country where they were made: The paintings on porcelain thus resembled those on enamel, and when the pieces were of considerable dimensions, and painted by distinguished artists, became of great value. Thus, copies of works of Raphael and of Tintoretto, in the Exhibition of 1851, were valued at £1000 and £880. Even ordinary cups, painted with vignettes, have their value much augmented. So also the application of delicate colors, as blue, green, and rose-pink, added a charm not found in the monochrome glazed ware of the middle ages. For these, Dresden and Sèvres were formally unrivalled; but the colors of late years have been changed, and do not equal the old.

The style of art has varied in each century; the old rococo shapes having been superseded at the commencement of this century by classical shapes, and again by modified medieval forms. The present age has been distinguished by an attempt to reproduce *majolica patissy*, and other wares; by the improvement of printing in colors; by the invention of statuary porcelain, and an application of the material to other purposes, as buttons, stamped or pressed from a mould or die. Besides the ornamentation of vases, a trade-mark is often added, either stamped in or painted on the ware. This, on the early majolica, had the date, place, and name of the artist; but the Dresden, Sèvres, Chelsea, and other establishments introduced devices, monograms, arms, &c., as swords, anchors, crowns, and other devices. The Chinese have devices, mottoes, names of makers, and the date of the reign when made, commencing with the first monarch of the Ming dynasty about 1480, generally in red color, and imitating the seals or stamps used for sealing documents. These marks are continued to the present day (see below).

Manufacture.—The dough-like condition into which clay can be worked with water, and the hardness it may be made to acquire by burning, are qualities which have been turned to account by man from the earliest times, and it is upon these that the potter's art essentially depends; but there is great variety in clay, and it is only by knowing something of its nature and constituents, that any real advance has been effected in pottery. If a piece of clay be examined, it will be found that it consists of exceedingly minute particles, held together by aggregation when moist; but if dried, it can be easily reduced to an impalpable powder by mere pressure; and if, instead of drying, we add an excess of water, it may be so mixed and held in suspension in the water that it appears almost to be dissolved. In time, however, it is deposited as a sediment, and when the excess of water is removed, it is a soft tenacious paste, which is so non-elastic that it will retain the smallest impression made in it without change. This minute division of its particles, and the absence of elasticity, are its most valuable qualities. But all clays are not of the same purity and quality; the commonest is that of brick-fields, which is one of the most abundant substances in nature; but it is so mixed up with iron and other foreign ingredients, that except for bricks, tiles, and the coarsest kinds of pottery, it is not used.

The purest kinds of potters' clay are called *kaolin*, and are believed to have been formed by the decomposition of rocks containing large proportions of felspar, a slightly variable compound substance, which, in general terms, may be said to be a combination of neutral silicate of alumina and the silicates of potash, soda, lime, or magnesia, together or singly. Certain kinds of granitic rocks, especially the whiter varieties, by their atmospheric decomposition, yield fine kaolin. Great experience is required in selecting and using the materials, because in nature the plastic materials are very irregularly mixed with other substances, which have a more or less deteriorating effect. Most of the best known clays contain a certain portion of free silica in addition to that in combination as natural silicate, which requires to be removed for very fine wares by boiling in caustic potash, otherwise, it proves injurious. The finest china-clay of Great Britain is obtained from Cornwall, where the decomposed granite is washed by streams of water, which carry it away into ponds called *catch-pools*. The discovery of this source of china-clay was made by Mr. Cookworthy about the middle of last century, and alone afforded means for improving our native pottery, which were most admirably turned to account by Mr. Josiah Wedgwood, and after him, by Mr. Herbert Minton, Mr. Copeland, and others. Previous to this, although, as before noticed, fine pottery was

made in Britain in two or three places, yet the general character of our pottery, which was chiefly manufactured in the neighborhood of Burslem, in Staffordshire, was most miserable both in material and in design. The clay was inferior in color, prepared with very little care, and covered with a coarse white or yellow lead glaze; but the discovery of the Cornish clay, by affording a material of excellent quality, stimulated the manufacturers to improve the general style of their manufacture.

Scarcely second in importance to this discovery was Wedgwood's good taste and untiring zeal in working out that revolution in the art of the British potter, that has led to its present enormous development. In 1730, when Wedgwood was born at Burslem, in Staffordshire, that place supplied the greater part of the common household pottery of Great Britain; but so small was the trade, that it was but little more than a village encumbered with heaps of broken crockery, and its environs disfigured with clay-pits and piles of refuse; now it is the center of a populous district called "The Potteries," comprising about 48 square miles. In this limited space there are now nearly 280 kilns at work, employing more than 100,000 operatives.

The method pursued in making pottery and porcelain is the same in principal everywhere; we shall therefore give the general outline of the process without entering into the minute differences which distinguish the variations produced by different manufacturers in this and other countries. Pottery and porcelain differ chiefly in this, that the superior quality of the materials used in making the latter, gives it a peculiar translucency. For pottery, inferior materials are used, and a considerable admixture of calcined flint, bone-ashes, or native phosphate of lime, are added to the clay. The use of the calcined flint was said to have been first adopted by a Burslem potter named Astbury, who, whilst traveling to London on horseback, in the year 1720, had occasion, in passing through Dunstable, to seek the assistance of an hostler,

Fig. 14.

in consequence of some disease in his horse's eyes. He noticed that the man took a piece of flint, burned it, and then reduced it to a fine powder, which he blew into the horse's eyes. Astbury noticing the beautiful whiteness of the powder, conceived the idea of using it in his pottery; and did so with great success.

The ingredients, such as the clay and calcined flints, are ground by separate means; the former in the pug-mill, which is represented in fig. 14. This is an upright, iron-bound, wooden cylinder, with an axis A turned by machinery; projecting from A are seven arms, each of which has three knives fixed in it, with the points outward, and so arranged that they spread over the largest amount of space in the interior; and altogether they are placed in a spiral manner, so that when in motion, the clay, which is thrown in lumps into the hopper-shaped upper part of

Fig. 15.

the vat, is worked down, and is so cut and kneaded by the knives, that it is forced out at an opening at C, in the state of soft sap. This is aided by the knives on the lower part of the lowest arm being connected together by a plate D, which pre-

vents all settlement at the bottom. This pap-like clay passes into a large wooden tank, in which it is agitated with water until quite incorporated, so as to resemble milk in color and consistency. In another mill (fig. 15), of a different construction, the Cornish granite and calcined flints are being reduced to a somewhat similar state. This mill is very strongly constructed, and consists of a tub-like vat A, in the center of which turns an axle B, moved by machinery; in the bottom of the vat is a thick stone-bed C, consisting either of chert or horn stone.

From the upper part of the axis, three strong arms, D, D, D, project like the spokes of a wheel; and strongly attached to these are stout beams, *a*, pointing downward, and nearly touching the stone-bed C. As the axis, with its arms and beams, turns round, the beams push some large masses of the Cornish granite or of chert stone round with them, and these triturate the calcined flints and other hard materials, and stir up the water with which the vat is kept constantly supplied, whilst it overflows in a milky state, charged with the finely-divided materials, into a cistern, where it is kept stirred until it is sufficiently supplied with the solid materials, and the thickened milky liquid is then drawn off, in proper proportions, into a vat to which the prepared clay is also passed. The mixture of the two is then allowed to subside until the water is nearly clear, when it is drawn off; and the sediment is deprived of its surplus moisture, either by evaporation, or, in the best works, by a pneumatic-exhausting apparatus, which does it very quickly. The composition is then a fine plastic material of the consistency of tough dough, and is ready for the potter's use. In preparing the finer materials for porcelain, many other operations are required, all, however, having the same object, viz., the extremely minute division of the substances used.

The prepared clay is taken to the *throwing-machias*, or *potter's lathe*, which is represented in fig. 16. This consists of a fixed table A, through which passes the axle B, and rises a little above

Fig. 16.

its surface, and having on its upper end a disc C, which revolves with it. The axle is put into rapid motion by turning the fly-wheel D, either by hand or machinery; and this causes a rapid revolution of the disc C, upon which is placed the soft mass of clay to be moulded. At E is seen an upright, with a small sliding-bar regulated by a screw; this is the guide for the potter to regulate the height of the vessel he is making. When the lump of clay is revolving, the potter, with his hands or with proper

Fig. 17.

Fig. 18.

Fig. 19.

tools, fashions it into any shape he pleases; his management of this requires considerable skill, as nearly every article requires a different configuration. But some articles are formed in moulds, the moulds being made of plaster of Paris. This answers well for fine porcelain intended to be very thin, because the plaster-mould absorbs much of the moisture in the paste, and thus partially dries it, so that it admits of handling, which in a softer state would be very difficult. The paste is used so liquid that it can be poured into the moulds. It is usual, in casting, to have a mould for each part, as seen in figs. 17, 18, 19, which represent the body, neck and lip, and foot of the cream-ewer, fig. 20.

For nearly flat articles, such as dinner-plates, a plan is adopted which combines both processes: a mould, usually of plaster, fig. 21, *a*, is placed on the disc of the throwing-wheel, *b*, and a thin layer of the paste is pressed on to it, so as completely to take its form; then to the guide-post, *c*, is attached an arm, *d*, with a

small brass plate, *e*, on its lower side. This plate is cut to the outline of half the plate, or dish; as it revolves, this pares down

Fig. 20.

and shapes the clay to its own outline, and to the thickness to which it is set, there being an arrangement on the arm of the guide-post by which this can be effected. Sometimes, as in the case of deep vessels, moulds are used for the exterior, and the interior is formed by the hand. This process (fig. 22) insures certainty of size and shape, which is important in making large numbers of similar articles, as tea-cups, &c. The mould is lined with a thin cake of clay, and when placed on the revolving disc, it is fashioned inside by hand, and finished off with a wet sponge.

Fig. 21.

Fig. 22.

Sometimes metal or horn tools are used for producing mouldings and other raised ornaments, or for grooves, when the turning or throwing wheel is used. If the articles made require handles or other similar accessory parts, they are always moulded, unless of very simple forms, and are attached whilst they and the body are still soft enough. They are joined by a thin fluid paste called a *slip*, and the junction is smoothed over with the wet sponge, which is one of the most useful of the potter's tools.

Being formed, the articles, of whatever kind, are now taken to the drying-stove, where they are placed on shelves, and remain there some time, exposed to a heat of about 85° Fahr. When quite dry, they are next taken to a workshop near the kiln, and they are here carefully packed in coarse earthenware vessels,

Fig. 23.

called *seggars* (fig. 23), which are so made that they can be piled upon one another to a great height in the kiln, as seen in fig. 24, in which some of the seggars are seen in section, for the purpose of making the arrangement more intelligible. As the seggars are generally made large enough to hold a number of articles, which would, when highly heated, adhere if they touched, a number of curiously shaped pieces of burned clay are used for placing between them, so as to make them rest on points; these are called

watches, cockspurs, triangles, stilts, &c., fig. 25. In the seggar, filled with plates (fig. 26), the plates are seen each resting on *cockspurs*, which prevent them touching. Another object is gained by this, in burning flat articles such as plates; these, if placed one upon another, would not be fired equally, but when they are held apart, the heat affects all parts alike. The seggars are so piled in the kiln that the center is hollow, and there are free spaces between them through which the fire can ascend; props, *a, a, a*, fig. 24, being so placed as to keep them from immediate contact with the sides all round. Thus, each seggar forms a small oven, in which one or more pieces of pottery or porcelain are baked, and the seggars prevent any unequal heating of the pieces, and also protect them from smoke.

Fig. 24.

A kiln has generally eight furnaces, and it is usual to raise six piles of seggars between every two furnaces, or rather between their flues, which rise to a considerable height in the kilns. Each pile of seggars is technically called a *bung*, so that there are generally 48 or 50 bungs to the charge of a kiln. When all this is arranged, the furnaces are lighted, and great care is taken to have the best coal, as it enables the manufacturer to make a more certain calculation as to its effects, and is less liable to smoke and sulphureous vapors, which might injuriously affect the contents of the kiln. The baking or firing requires great care and attention, and there are many nice regulations connected with it to guide the workman. It usually lasts from 40 to 42 hours. The fire is then allowed to go out, and the kiln to cool very gradually, after which it is opened, and the seggars removed, to be unpacked in a separate workshop. The articles are now in the state called

Fig. 25.

biscuit-ware, and require both the glaze and any patterns they may be intended to bear. Common pottery is often figured by printing the design in enamel colors on paper, and whilst the printing is still wet, applying it to the biscuit-ware; the ware absorbs the enamel ink, and the paper is removed by water, leaving the pattern on the ware. It is then fired in seggars, or a muffle, to fix the color, and is then dipped into composition called *glaze*, of which three kinds are used in the Staffordshire potteries. The first, for common pipeclay ware, is composed of Cornish granite, 16 parts; flint, 36 parts; white-lead, 53 parts; and cullet, or broken flint-glass, 4 parts. These materials are triturated with water, with the same care and by similar means to those employed

in forming paste, and are reduced with water to the same milk-like liquidity.

Each workman has a tub of the glaze before him; and as the articles of biscuit-ware, either with or without decorations, are brought to him, he dips them in the glaze, so as to insure a uniform coating over them; and by nice management, he prevents any large drops or accumulations on one part more than another. The porous biscuit-ware rapidly absorbs the moisture, and dries up the thin film of glaze on the surface of the articles, which are again placed in seggars, and carried to the glaze-kiln, where they undergo another firing, which melts the glaze, and converts it into a perfectly transparent glass, like water, all over the surface, and renders any pattern previously printed upon it very plain. The temperature in the glaze or enamel kiln is only increased very gradually, and is kept up for about 14 hours, after which it is allowed to cool slowly, and the articles are taken out completed. So far, this description has applied to the manufacture of pottery and porcelain on a large scale, for general purposes;

Fig. 26.

Fig. 27.

but when it is applied to more costly and artistic works, very special arrangements are required; and in the case of remarkably fine pieces, instead of the huge kilns, which hold frequently many thousand pieces, muffle furnaces (fig. 27) are both used for the biscuit, the glaze, and the colored and gilded decorations, which, in porcelain, are applied on the glaze, and not on the biscuit.

The decoration of porcelain has long held a high rank as a fine art; and the exquisite skill shown in some of the finest works of the continental manufactures, and lately in those of Britain, has fairly entitled it to that rank. The colors employed are all colored glasses ground to impalpable powders, and mixed with borax or some other fluxing material; for use, they are generally made liquid with oil of spike, and they are laid on with hair-pencils, in the same way as oil-colors. The whole process is exactly the same as in painting or staining glass; the glaze on the biscuit-porcelain being true glass, and the enamel colors being exactly the same as those used by the glass decorator. The colors may be made by mixing the materials of which glass is made with the coloring material and the flux, or simply with the already colored glass and the flux. When the former plan is employed, the following are the coloring materials employed: oxide of chromium for green; oxide of iron for red, brown, violet, gray, and yellow; oxide of uranium for orange, yellow, black; oxide of manganese for violet, brown, black, and purple; oxide of cobalt for blue, gray, and black; oxide of antimony for yellow; oxide of titanium for yellow; oxide of copper for green; suboxide of copper for red; sesquioxide of iridium for fine black; protochromate of iron for brown; chromate of lead for yellow; chromate of barytes for yellow; chloride of silver for deepening reds and purples; purple of cassius for ruby and purple. Several of these colors are much increased in brilliancy by the addition of oxide of zinc, which of itself gives no color; and the transparent ones are rendered opaque by the addition of oxide of tin.

Other fluxes besides borax, or borate of soda, are used—as sand, felspar, boracic acid, minium or litharge, salt, saltpetre, potash, and soda. Nothing enriches the appearance of porcelain more than good gilding; for this purpose, gold-leaf is rubbed down with oil of turpentine; or pulverulent gold is produced by precipitating a solution of gold in aqua regia, by the addition of a solution of sulphate of iron. The gold is precipitated as a brown powder, which is washed and dried, and then worked up with one-sixteenth of its weight of oxide of bismuth and oil of turpentine. It is painted on, then fired, and afterwards burnished. Peculiar and beautiful metallic lustres are produced upon pottery by precipitated platinum and other means; but it is not within

the scope of this article to enter into all the details by which the almost numberless variations are produced in the manufacture and decoration of this material. The literature relating to its history is rich in treatises for the guidance of those engaged in the art.

The following are the chief varieties of ceramic materials and their usual composition: 1. *Porcelain*.—At Sèvres, kaolin, 48 parts; sand (pure white), 48 parts; chalk, 4 parts. At Dresden, kaolin, 62 parts; felspar, 26 parts; broken biscuit-porcelain, 2 parts. At Berlin, kaolin, 76 parts; felspar, 24 parts. In England, three mixtures are used.—For common china, ground flints, 75 parts; calcined bones, 180 parts; china-clay, 40 parts; clay, 70

parts. For fine china, ground flints, 66 parts; calcined bones, 100 parts; china-clay, 96 parts; Cornish granite, 80 parts. Fine, for modelling figures, &c., Lynn sand, 150 parts; calcined bones, 300 parts; china-clay, 100 parts; potash, 107 parts. The glazes require to be varied for nearly all, so that their fusibility may be greater or less, according to the more or less fusible character of the biscuit ingredients. 2. *Parian*.—The composition for this is the same as that for the fine English china, but it is used in a liquid state, so as to be poured into the plaster of Paris moulds. It requires very great care in the firing. 3. *Earthenware* (Fr. *faïence* from Fayeenza, the name of a place in Italy where it was made; Dutch, *Delft*, from its having been chiefly made at Delft, in Holland).—

1, Pennington, Liverpool, 1780—1780; 2, Plymouth, about 1760; 3, Richard Champion, Bristol, 1772—1790; 4, Charles Green, Leeds, 1790; 5, Bow, 1730—1790; 6, Absolon, Yarmouth, about 1790; 7, Chelsea, 1730—1784; 8, Swansea, Wales, 1790; 9, Worcester, 1790—1780; 10, Yarmouth, about 1790; 11, Derby, 1731—1769; 12, Crown, Derby, 1780—1850; 13, Shropshire, 1772—1799; 14, Cookworthy, Plymouth, 1760; 15, Derby—Chelsea, 1770.

Made of various kinds of clay, varying in color from yellow to white, according to the quality required; and more or less of powdered calcined flints, are mixed with it, to give it body and hardness. Sometimes, as in porous vessels, only clay is used. 4. *Stoneware*, such as is used for jars, bottles, drain-pipes, &c., is made of several kinds of plastic clay, mixed with felspar and sand, and occasionally a little lime, but the materials vary much in different localities.

In Great Britain, the potteries not only supply the home demand, but also export to a greater extent than any others in Europe; and so rapid and extensive have been the improvements effected in the last ten years by British potters, that, both as a manufacturing and as an artistic country, Great Britain now stands foremost. In 1880 the exports of earthen and china ware, parian and porcelain (except red pottery and brown stone-ware), amounted in value to £1,978,445. The largest quantities are sent to India, North America, and Australia. In North America, however, the manufacture of pottery is carried on with great activity in Jersey, Philadelphia, Liverpool (in Ohio), and other places.

Most of the celebrated manufacturers of pottery and porcelain, both at home and abroad, have employed a special mark to distinguish their works, and these are now of considerable importance in enabling us to ascertain the origin of choice specimens. The above illustration give some of the more important marks and monograms, so used by the earlier English makers, when their names in full were not imprinted, as was often the case.

PO'TTŌ. See KINKAJOU.

PO'TTSVILLE, a city of Pennsylvania, on the Schuylkill River, at the entrance of Norwegian Creek, 93 miles north-west of Philadelphia, with which it is connected by railway. It is in the midst of a rich anthracite coal and iron region, and has several iron foundries, a brass foundry; manufactures of iron safes, sashes, and wood-work; county buildings; 10 banks; 3 English, 3 German, and 1 Welsh paper; and 19 churches, 3 of which are Welsh. Pop. (1870) 12,384; (1880) 13,253.

POTY, a district town, and rising seaport of Russia, in the Caucasian government of Kutais, stands at the mouth of the river Rion, on the eastern shore of the Black Sea. The Rion connects the port with the interior, and since the establishment of regular steam communication by the Russian Trade and Navigation Company in this quarter, the commerce and especially the transit-trade of this town has greatly increased. It is connected by railway with Tiflis. Pop. (1867) 1809.

POUCH, MILITARY, a stout leather box, black or brown, lined with tin, covered with a strong flap, and ornamented with the device of the regiment, serves to carry the cartridges required by a soldier for immediate use. When cartridges are supplied for a whole day's service, two pouches are worn, one on the front point of the hip, and a larger one on a belt suspended over the left shoulder.

POUCHED RAT (*Pseudostoma*), a genus of *Murida*, of which there are several species, natives of parts of North America west of the Mississippi, and some of them very troublesome from the ravages they commit in fields and gardens. They have four molars on each side in each jaw. The tail is short. The cheeks are furnished with pouches, to which the name refers, the openings of which are from the outside, and not from the mouth. The pouched rats burrow in the ground, and do great mischief to root-crops.
